**PREFACE**

The work documented here was performed by the SERI Renewable Resource Assessment Branch for the U.S. Department of Energy under Task No. 1093.00. The report compares several simple global horizontal insolation models with several rigorous radiative transfer models and describes an improved, simple, global insolation model. We would like to thank J. V. Dave of IBM for providing data sets from his Spherical Harmonics code.

## NOMENCLATURE

$a_i$	Absorptance parameters defined by Hoyt
$a_{CO}$	Carbon dioxide absorptance
$a_{OX}$	Oxygen absorptance
$a_W$	Water vapor absorptance
$B_a$	Ratio of the forward-scattered irradiance to the total scattered irradiance due to aerosols
$F_{zj}$	A parameter used by Watt in air mass calculations
$I_{as}$	Solar irradiance on a horizontal surface from atmospheric scattering ( $W/m^2$ )
$I_d$	Direct solar irradiance on a horizontal surface ( $W/m^2$ )
$I_G$	Solar irradiance on a horizontal surface from multiple reflections between the ground and sky ( $W/m^2$ )
$I_s$	Solar irradiance on a horizontal surface from scattered light ( $I_{as} + I_G$ )
$I_T$	Total (global) solar irradiance on a horizontal surface ( $W/m^2$ )
$I_o$	Extraterrestrial solar irradiance ( $1353 W/m^2$ )
$K$	Aerosol transmittance for Davies and Hay
$K_1$	Constant used in Bird model associated with aerosol absorptance
$M$	Air mass
$M'$	Pressure-corrected air mass
$M_i$	Watt's path length modifier (similar to air mass)
$P$	Surface pressure (millibars)
$r_g$	Ground albedo
$r_s$	Sky, or atmospheric, albedo
$T$	Surface temperature (K)
$T_A$	Transmittance of aerosol absorptance and scattering
$T_{AA}$	Transmittance of aerosol absorptance

$T_{AS}$	Transmittance of aerosol scattering
$T_{as}$	Transmittance of dry air absorptance and scattering for Watt
$T_L$	Transmittance of lower layer aerosol for Watt
$T_M$	Global transmittance of all molecular effects except water vapor for Atwater
$T_{Md}$	Direct transmittance of all molecular effects except water vapor for Atwater
$T_O$	Transmittance of ozone absorptance
$T_R$	Transmittance of Rayleigh scattering
$T_U$	Transmittance of upper layer aerosol for Watt
$T_{UM}$	Transmittance of absorptance of uniformly mixed gases (carbon dioxide and oxygen)
$T_w$	Transmittance of water vapor absorptance ( $1 - a_w$ )
$T_{ws}$	Transmittance of water vapor scattering
$U_O$	Amount of ozone in a vertical column from surface (cm)
$U_w$	Amount of precipitable water in a vertical column from surface (cm)
$X_O$	Total amount of ozone in a slanted path (cm)
$X_w$	Total amount of precipitable water in a slanted path (cm)
$Z$	Angle between a line to the sun and the local zenith (zenith angle in degrees)
$\alpha_{cs}$	An attenuation multiplier used by Watt
$\tau_A$	Broadband aerosol optical depth from surface in a vertical path (broadband turbidity)
$\tau_{0.5}$	Aerosol optical depth from surface in a vertical path at 0.5- $\mu$ m wavelength
$\tau_{0.38}$	Aerosol optical depth from surface in a vertical path at 0.38- $\mu$ m wavelength
$\tau_L$	Lower layer aerosol optical depth in a vertical path for Watt
$\tau_u$	Upper layer aerosol optical depth in a vertical path for Watt
$W_O$	Single scattering albedo--the fraction of the light lost from an incident pencil of radiation that is due to scattering

## SECTION 1.0

### INTRODUCTION

To properly design a solar energy system for a location lacking an insolation data base, insolation models are required. This need for insolation models has been recognized for many years. One early and widely used insolation model was published in 1940 by Moon [1]. This model is still used today in its original or modified forms [2,3].

Insolation models have proliferated to the point where it is difficult for a solar user to decide which model to adopt. The purpose of this paper is to provide a detailed comparison of several simple, broadband insolation models that are currently in use and, based on this comparison and comparisons with more rigorous radiative transfer models, to formulate a simple clear sky model for direct and diffuse insolation. This type of comparison should be helpful in evaluating the relative accuracy of various models and give direction for formulating a model that uses the best of each existing model. The criteria used for evaluating and formulating models have been simplicity, accuracy, and the ability to use readily available meteorological data.

It should be noted that the use of the word "rigorous" does not necessarily mean that the "rigorous" results truly represent reality. Even though these "rigorous" codes are very detailed in the methods used to solve the radiative transfer problem, the representativeness of the results depends upon how well the atmospheric model, the measured atmospheric parameters, the mathematical methods, and other assumptions made in the codes relate to a real situation. However, in the absence of well-documented data, this approach of using "rigorous" codes as a basis of comparison was used.

## SECTION 2.0

### DESCRIPTION OF MODELS

A brief description of the several models that have been compared is presented here. Further details of this comparison can be found in Ref. 4 and in the original publications of each author. Most of the models include the effect of clouds, but this aspect of the models is not included here. Comparisons of cloud-cover global insolation models will follow (in a subsequent report) the clear sky model comparisons reported here. Such comparisons have also been performed by Davies and Hay [5].

#### 2.1 ATWATER AND BALL MODEL

Direct and global insolation models were published by Atwater and Ball [6,7]. The direct insolation model was taken from Kastrov as discussed by Kondratyev [8]. The equations of transfer and the transmission functions for this insolation model are given in Table 2-1. (The symbols in Tables 2-1 through 2-6 are defined in the Nomenclature.)

**Table 2-1. EQUATIONS FOR TOTAL DOWNWARD IRRADIANCE FOR ATWATER AND BALL MODEL**

---

#### Basic Equations

$$I_d = I_o (\cos Z) (T_{Md} - a_w) T_A$$

$$I_T = I_o (\cos Z) (T_M - a_w) T_A / (1 - r_g r_s)$$

#### Transmission Functions

$$T_{Md} = 1.041 - 0.16 [M(949 \times 10^{-6} P + 0.051)]^{0.5}$$

$$T_M = 1.021 - 0.0824 [M(949 \times 10^{-6} P + 0.051)]^{0.5}$$

$$a_w = 0.077 (U_w M)^{0.3}$$

$$T_A = \exp(-\tau_A M')$$

$$M = 35 / [(1224 \cos^2 Z) + 1]^{0.5}$$

$$M' = PM / 1013$$

---

The form of the equation for water vapor absorption was published by McDonald [9]. The value of  $r_s = 0.0685$  for a molecular atmosphere, as reported by Lacis and Hansen [10], was used with this model. Atwater and Ball

used MIE calculations to obtain  $\tau_A$ , which is much too rigorous for a simple model. Therefore, a value of  $\tau_A$  that will be described later in the Bird model was used here.

## 2.2 DAVIES AND HAY MODEL

A model for solar insolation (direct and diffuse) was published by Davies and Hay [5]. The equations used in this model were partially the result of comparing several existing models, and they are presented in Table 2-2.

Table 2-2. EQUATIONS FOR TOTAL DOWNWARD IRRADIANCE FOR DAVIES AND HAY MODEL

### Basic Equations

$$I_d = I_o (\cos Z) (T_o T_R - a_w) T_A$$

$$I_{as} = I_o (\cos Z) [T_o (1 - T_R) T_A (0.5) + (T_o T_R - a_w) (1 - T_A) W_o B_a]$$

$$I_G = r_g r_s (I_d + I_{as}) / (1 - r_g r_s)$$

$$I_T = I_d + I_{as} + I_G$$

### Transmission Functions

$$T_o = 1 - 0.02118X_o / (1 + 0.042X_o + 0.000323X_o^2) - 1.082X_o / (1 + 138.6X_o)^{0.805} - 0.0658X_o / [1 + (103.6X_o)^3]$$

$$X_o = U_o M$$

$$a_w = 2.9X_w / [(1 + 141.5X_w)^{0.635} + 5.925X_w]$$

$$X_w = U_w M$$

$$T_A = K^M$$

$$r_s = 0.0685 + (1 - B_a)(1 - T_A)W_o$$

The expressions for ozone transmittance,  $T_o$ , and water vapor absorption,  $a_w$ , were taken from Lacis and Hansen [10]. The transmission due to Rayleigh scattering,  $T_R$ , was presented in tabular form, and so we used the Bird model expression for  $T_R$  in this model. The value  $K = 0.91$  was used for data generated here and is representative of aerosol conditions in southern Ontario.  $W_o = 0.98$  and  $B_a = 0.85$  were used here also.

## 2.3 WATT MODEL

Another direct and diffuse insolation model has been constructed by Watt [3], based partially on the work of Moon [1]. The equations for this model are shown in Table 2-3.

**Table 2-3. EQUATIONS FOR TOTAL DOWNWARD IRRADIANCE FOR WATT MODEL**

### Basic Equations

$$I_d = I_o (\cos Z) T_{wa} T_{as} T_o T_{ws} T_L T_U$$

$$I_s = I_o [0.8 r_s (1 + r_g r_s) (1 + \cos Z)^{0.5} + 0.5 \alpha_{cs} r_g r_s \cos Z + 0.5 r_s \cos Z]$$

$$I_T = I_d + I_s$$

### Transmission Functions

$$T_w = 0.93 - 0.033 \log (U_w M_2)$$

$$T_{as} = 10^{-0.045 [(P/P_o) M_1]^{0.7}}$$

$$T_o = 10^{-(0.0071 + 0.01 U_o M_4)}$$

$$T_{ws} = 10^{-(0.0095 U_w M_2)}$$

$$T_L = 10^{\tau_L M_2^{0.7}}$$

$$T_U = 10^{-\tau_u M_3}$$

$$\tau_L = 0.6 (\tau_{0.5} - 0.01 U_w - 0.03)$$

$$\alpha_{cs} = (0.93 - 0.033 \log U_w) 10^{-[0.006 P/1013 + 0.4 (T_L + T_U)]}$$

$$r_s = \alpha_{cs} \{1 - 10^{-[0.003 P/1013 + 0.01 U_w + 0.4 (T_L + T_U)]}\}$$

$$M_i = \sec Z \text{ for } Z \leq 70^\circ \text{ (i = 1, 2, 3, 4)}$$

$$M_i = (h_2 F_{z2} - h_1 F_{z1}) / (h_2 - h_1) \text{ for } Z > 70^\circ \text{ (i = 1, 2, 3, 4)}$$

$$F_{zj} = \{ [(r/h_j) \cos Z]^2 + 2 r/h_j + 1 \}^{0.5} - (r/h_j) \cos Z \text{ (j = 1, 2)}$$

$$\text{for } i = 1, h_1 = 0 \text{ km and } h_2 = 30 \text{ km}$$

$$i = 2, h_1 = 0 \text{ km and } h_2 = 3 \text{ km}$$

$$i = 3, h_1 = 15 \text{ km and } h_2 = 25 \text{ km}$$

$$i = 4, h_1 = 20 \text{ km and } h_2 = 40 \text{ km}$$

The upper layer broadband turbidity,  $\tau_u$ , was not well defined by Watt. A value of  $\tau_u = 0.02$  was used in the calculations performed here, which appears to be an average value for locations in the United States. The parameter  $r$  is the earth's radius ( $6.4 \times 10^6$  m).

## 2.4 HOYT MODEL

The equations used in the model by Hoyt [11] are shown in Table 2-4.

Table 2-4. EQUATIONS FOR TOTAL DOWNWARD IRRADIANCE FOR HOYT MODEL

### Basic Equations

$$I_d = I_o (\cos Z) \left( 1 - \sum_{i=1}^5 a_i \right) T_{AS} T_R$$

$$I_{as} = I_o (\cos Z) \left( 1 - \sum_{i=1}^5 a_i \right) [(1 - T_R)0.5 + (1 - T_{AS})0.75]$$

$$I_G = (I_d + I_{as}) r_g \left( 1 - \sum_{i=1}^5 a_i' \right) [(1 - T_R')0.5 + (1 - T_{AS}')0.25]$$

$$I_T = I_d + I_{as} + I_G$$

### Transmission Functions

$$a_1 = a_w = 0.110 (0.75 U_w M + 6.31 \times 10^{-4})^{0.3} - 0.0121$$

$$a_2 = a_{co} = 0.00235 (126 M' + 0.0129)^{0.26} - 7.5 \times 10^{-4}$$

$$a_3 = (1 - T_o) = 0.045 (U_o M + 8.34 \times 10^{-4})^{0.38} - 3.1 \times 10^{-3}$$

$$a_4 = a_{ox} = 7.5 \times 10^{-3} (M')^{0.875}$$

$$a_5 = 0.05 T_{AS}$$

$$M' = MP/1013.25$$

Hoyt obtained air mass values,  $M$ , from Bemporad's [12] tables. The expression for air mass of Kasten [13] was used here instead. The values of  $T_{AS}$  and  $T_R$  are calculated from tables furnished by Hoyt [11]. The  $a_i'$  values are calculated using air mass values of  $M' + 1.66 P/1013.25$  in the  $a_i$  expressions.

$T_{AS}'$  and  $T_R'$  are evaluated for air mass values of 1.66 P/1013.25 in  $T_{AS}$  and  $T_R$ . The table values from which  $T_{AS}$  is calculated are limited so that large optical depths cannot be considered. Large optical depths can occur from high turbidity or from large zenith angles. In the data presented later for  $Z = 80^\circ$ , an approximate value of  $T_{AS}$  was used to complete the plotted results.

## 2.5 LACIS AND HANSEN MODEL

The equations for the model developed by Lacis and Hansen [10] are shown in Table 2-5.

**Table 2-5. EQUATIONS FOR TOTAL DOWNWARD IRRADIANCE FOR LACIS AND HANSEN MODEL**

### Basic Equation

$$I_T = I_0 (\cos Z) [(0.647 - r_s' - a_o)/(1 - 0.0685 r_g) + 0.353 - a_w]$$

### Transmission Functions

$$r_s' = 0.28/(1 + 6.43 \cos Z)$$

$$a_o = 1 - T_o \text{ as shown in Table 2-2}$$

$$a_w = \text{Shown in Table 2-2 with the following correction:}$$

$$X_w = X_w(P/1013)^{0.75}(273/T)^{0.5}$$

## 2.6 BIRD MODEL

A model has been constructed that is based on comparisons with the SOLTRAN 3 and SOLTRAN 4 [4] direct insolation models and the BRITE Monte Carlo global model [14]. Formalisms in the previous models that were considered to be optimum were adopted here. The equations for this model are shown in Table 2-6.

The atmospheric turbidity values,  $\tau_{A,0.38}$  and  $\tau_{A,0.5}$ , have been measured on a regular basis by the National Weather Service [15] at 0.38- and 0.5- $\mu\text{m}$  wavelengths, respectively. If one of the turbidity values is not available, its value can be entered as a zero in the expression for  $\tau_A$ . The expression for  $\tau_A$  is based on the Air Force Geophysics Laboratory (AFGL) rural aerosol model [16]. The expression used here for  $T_{AA}$  was found by fitting the expression to the results of the SOLTRAN 4 [4] code. The value of  $K_1 = 0.0933$  for the rural aerosol was used here for all calculations. For the urban aerosol model, which contains more carbon, the value of  $K_1 = 0.385$  was found to be appropriate. From a theoretical standpoint,  $K_1$  should be nearly equal to  $1 - W_o$ , where  $W_o$  is the single scattering albedo. The forward-scattering

**Table 2-6. EQUATIONS FOR TOTAL DOWNWARD IRRADIANCE FOR THE BIRD MODEL**
Basic Equations

$$I_d = I_o (\cos Z) (0.9662) T_R T_o T_{UM} T_w T_A$$

$$I_{as} = I_o (\cos Z) (0.79) T_o T_w T_{UM} T_{AA} \\ [0.5 (1 - T_R) + B_a (1 - T_{AS})] / [1 - M + (M)^{1.02}]$$

$$I_T = (I_d + I_{as}) / (1 - r_g r_s)$$

Transmission Equations

$$T_R = \exp \{-0.0903 (M')^{0.84} [1 + M' - (M')^{1.01}]\}$$

$$T_o = 1 - 0.1611 X_o (1 + 139.48 X_o)^{-0.3035} \\ - 0.002715 X_o (1 + 0.044 X_o + 0.0003 X_o^2)^{-1}$$

$$X_o = U_o M$$

$$T_{UM} = \exp [-0.0127 (M')^{0.26}]$$

$$T_w = 1 - 2.4959 X_w [(1 + 79.034 X_w)^{0.6828} + 6.385 X_w]^{-1}$$

$$X_w = U_w M$$

$$T_A = \exp [-\tau_A^{0.873} (1 + \tau_A - \tau_A^{0.7088}) M^{0.9108}]$$

$$\tau_A = 0.2758 \tau_{A,0.38} + 0.35 \tau_{A,0.5}$$

$$T_{AA} = 1 - K_1 (1 - M + M^{1.06}) (1 - T_A)$$

$$T_{AS} = T_A / T_{AA}$$

$$r_s = 0.0685 + (1 - B_a) (1.0 - T_{as})$$

$$M = [\cos Z + 0.15(93.885 - Z)^{-1.25}]^{-1}$$

$$M' = MP/1013$$

ratio,  $B_a$ , is related through MIE theory to a parameter  $\langle \cos \theta \rangle$ , called the asymmetry factor, by

$$B_a = 0.5(1 + \langle \cos \theta \rangle)$$

The asymmetry factor is the mean of the cosine of the scattering angle,  $\theta$ , with the angular intensity as the weighting function. The extreme values of  $B_a$  are

$$B_a = \begin{cases} 1 & \text{for all forward scattering;} \\ 0.5 & \text{for isotropic scattering;} \\ 0 & \text{for all backward scattering.} \end{cases}$$

Table 2-7 contains values of the asymmetry factor at various wavelengths for the rural aerosol model and the haze L aerosol model used by Dave [17]. Two differences in these aerosol models are: (1) the rural aerosol model is bimodal, whereas Dave's model has a single mode; and (2) the rural aerosol model varies the complex index of refraction with wavelength, and the Dave model holds it constant. The values of the asymmetry factors for the two models are in reasonably good agreement, and our calculations indicate that the Bird model is relatively insensitive to small changes in this parameter. A value of  $B_a = 0.82$  was used for the rural aerosol, and  $B_a = 0.86$  for Dave's aerosol in calculations shown later.

**Table 2-7. VALUES OF THE ASYMMETRY FACTOR  
FOR THE RURAL AND THE DAVE HAZE  
L AEROSOL**

Rural		Dave Haze L	
$\lambda$	$\langle \cos \theta \rangle$	$\lambda$	$\langle \cos \theta \rangle$
0.325	0.66	--	--
0.35	0.66	0.35	0.73
0.4	0.65	--	--
0.5	0.64	0.455	0.72
0.63	0.64	0.635	0.71
0.7525	0.63	0.7525	0.71
0.86	0.63	--	--
0.9935	0.63	0.994	0.70
1.235	0.64	1.235	0.69
1.497	0.65	1.61	0.67
1.8	0.68	2.1	0.63
2.198	0.71	2.198	0.62

It is suggested that values of  $B_a = 0.84$  and  $K_1 = 0.1$  be used with this model unless good information on the aerosol is available. All other data required by the model comes from meteorological measurements near the site of interest.

Ozone measurements are sometimes difficult to obtain. Since ozone has a minor effect on broadband solar insolation, it is suggested that the method of Van Heuklon [18] could be used in lieu of real data.

The expression used for air mass in the Bird model comes from Kasten [13] and was used for all of the calculations reported here except for the Atwater and Ball model and the Watt model.

For the convenience of the reader, Table 2-8 itemizes the input parameters required for each of the simple models.

**Table 2-8. INPUT PARAMETERS REQUIRED FOR SIMPLE MODELS**

Model	Input
Atwater and Ball	Solar constant, zenith angle, surface pressure, ground albedo, precipitable water vapor, total ozone, broadband turbidity
Davies and Hay	Solar constant, zenith angle, surface pressure, ground albedo, precipitable water vapor, total ozone, aerosol single scattering albedo (0.98 suggested), aerosol forward scattering ratio (0.85 suggested), broadband aerosol transmittance
Watt	Solar constant, zenith angle, surface pressure, ground albedo, precipitable water vapor, total ozone, turbidity at 0.5- $\mu$ m wavelength, upper layer turbidity
Hoyt	Solar constant, zenith angle, surface pressure, ground albedo, precipitable water vapor, total ozone, turbidity at one wavelength
Lacis and Hansen	Solar constant, zenith angle, surface pressure, surface temperature, ground albedo, precipitable water vapor, total ozone
Bird	Solar constant, zenith angle, surface pressure, ground albedo, precipitable water vapor, total ozone, turbidity at 0.5- and/or 0.38- $\mu$ m wavelength, aerosol forward scattering ratio (0.84 recommended)

## 2.7 RIGOROUS CODES

Three rigorous codes have been used in this study as a basis for formulating the Bird model. One code is for direct normal irradiance and is called SOLTRAN 4 [4]. Two other codes, which include both the direct normal and the diffuse irradiance, are the BRITE [14] Monte Carlo code and the Dave [17] Spherical Harmonics code. In each of these codes, a multilayered atmospheric model can be constructed, where important atmospheric parameters are defined

at each layer. In this way, a fairly detailed atmosphere can be constructed that closely resembles the real atmosphere at a given time and specific location. Each code then uses its own technique to solve the radiative transfer problem.

These rigorous codes calculate the irradiance at a specified altitude, sun angle, and for an atmospheric model at discrete wavelengths. For comparison with the simple broadband models described previously, the spectral irradiance from the rigorous codes has to be integrated over wavelength.

The SOLTRAN 3 code, an earlier version of SOLTRAN 4, was used to formulate most of the transmittance functions found in the Bird model. This was accomplished by performing a least-square fit of each transmittance function to transmittance data from SOLTRAN 3 for each atmospheric constituent. Further details of this operation can be found in Ref. 4. SOLTRAN 3 was used because it was the only version available to us when this portion of the work was performed. The only difference in the two models that would be apparent in the results would be caused by a slight difference in the "continental" and "rural" aerosol models that are used in the two codes.

A comparison was made between data from the BRITE code and several of the simple clear sky global models. Based on this comparison and the author's judgment of the best expressions used in the simple models, a model for the diffuse irradiance was formulated. This simple model of the diffuse irradiance was then fine-tuned to provide good agreement with the BRITE code as well as results from the Dave Spherical Harmonics code.

It is appropriate to comment here that there are problems with the expressions used for the diffuse irradiance model. The general formalism for the diffuse transfer equation of some of the simple models was adopted even though it may not be as acceptable, based on the physics of the problem, as one would like. For example, a cosine of the solar zenith angle is included in the diffuse transfer equation. This implies that all of the diffuse radiation behaves just like the direct normal component. The cosine is used to calculate the irradiance falling on a horizontal surface. However, it is well known that the diffuse irradiance is much more complex than this. An example of a more rigorous but fairly simple formalism for the diffuse irradiance is found in Ref. 19, in which the diffuse radiation is divided into three components: an isotropic term, a term resulting from horizon brightening, and a circumsolar term. The circumsolar term is the only one that behaves very much like the direct normal radiation. For tilted surfaces, a ground reflection should be added to this diffuse model. Another problem with this formalism is associated with using transmittance expressions for diffuse radiation that were derived for direct radiation.

## SECTION 3.0

## MODEL COMPARISONS

Each of the simple models described in Section 2.0 was programmed on a computer to produce data for comparison. A comparison of the aerosol transmittance, the transmittance after molecular (Rayleigh) scattering, the water vapor ( $H_2O$ ) transmittance, and the ozone ( $O_3$ ) transmittance will be presented first. Then, a comparison between the direct, the diffuse sky, the diffuse sky/ground, and the global radiation for three different atmospheric models will be shown. Comparisons are made, where possible, between each of the simple model results as well as the results from the rigorous models.

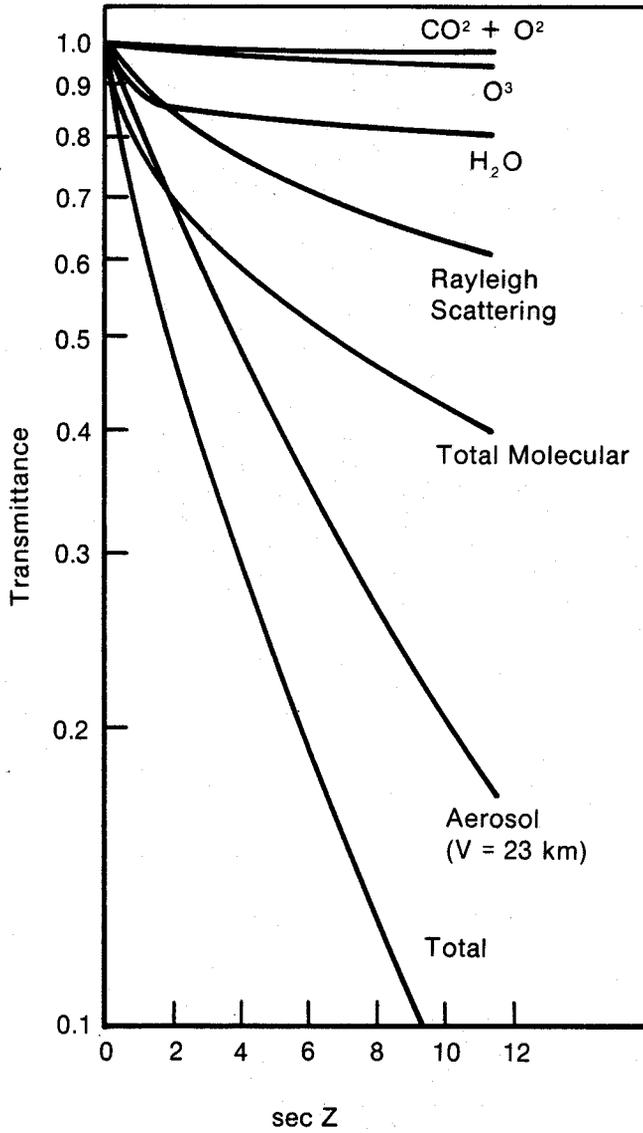

## 3.1 TRANSMITTANCE COMPARISONS

To become oriented as to the relative importance of each atmospheric constituent in atmospheric transmittance, the broadband transmittance versus the secant of the solar zenith angle (approximate air mass) for each constituent was plotted in Fig. 3-1. This figure was generated with output from the SOLTRAN 3 code for a Midlatitude Summer (MLS) atmospheric model. Table 3-1 shows the amounts of  $H_2O$  and  $O_3$  from sea level to the top of the atmosphere in a vertical column for the two atmospheric models--MLS and USS (U.S. Standard)--used in this comparison.

Table 3-1. AMOUNTS OF  $H_2O$  AND  $O_3$  IN A VERTICAL COLUMN FOR THE MLS AND USS ATMOSPHERES

	$H_2O$ (cm)	$O_3$ (cm)
MLS	2.93	0.31
USS	1.42	0.34

An examination of Fig. 3-1 shows that  $CO_2$  and  $O_2$  are the least important attenuators, and this is why they are not included in some models. The next element exhibiting increased attenuation is  $O_3$ , followed by  $H_2O$ . Molecular scattering dominates the total molecular absorption at large zenith angles and has a greater effect than most individual molecular species at all zenith angles. The most significant attenuator at all zenith angles is the aerosol. The aerosol modeled here was the continental aerosol model [16] with a sea level meteorological range of 23 km. A 23-km meteorological range is considered to be a moderately clear atmosphere. This aerosol produces an optical depth of 0.27 (base e) at 0.5- $\mu m$  wavelength.

**Figure 3-1. Transmittance versus Secant of Solar Zenith Angle for Midlatitude Summer Model**

The data in Fig. 3-1 indicate the relative effect that the atmospheric constituents have on the direct irradiance. However, when global irradiance is being considered these results can be misleading. A large fraction of the radiation lost in the direct beam by molecular and aerosol scattering is regained in the diffuse component. As a result of this, changes in aerosol optical depth through the atmosphere have less effect on the total global irradiance than on the direct irradiance.

Figures 3-2 and 3-5 present transmittance data for the USS atmosphere from several of the models. It should be pointed out that the broadband turbidity expression from the Bird model was used in the Atwater and Ball model. A similar effort could have been made with the aerosol transmittance term in the Davies and Hay model to produce identical results. One of the strengths of the Bird model is that it is based entirely on algebraic expressions for transmittance calculations rather than tabulated data. This makes the use of the model considerably easier and provides more flexibility.

The comparison made here for one model atmosphere is not really indicative of the accuracy of each model. Since a wide range of values of turbidity,  $H_2O$  amount, and  $O_3$  amount are required for real atmospheric conditions, the model must be able to accommodate these changes. Additional comparisons are presented in Ref. 4 for a range of these parameters. As was stated earlier, the transmittance expressions in the Bird model were derived from comparisons with SOLTRAN 3 results, but the comparisons made here are with SOLTRAN 4 results. This should have an effect only on the aerosol transmittance shown in Fig. 3-2. The transmittance comparisons shown in Figs. 3-2 through 3-5 are rather self-explanatory, and so no further discussions are presented.

### 3.2 IRRADIANCE COMPARISONS

The global solar irradiance has been divided into three components: the direct irradiance on a horizontal surface, the diffuse sky irradiance on a horizontal surface, and the diffuse ground/sky irradiance on a horizontal surface. The diffuse sky irradiance is the total diffuse radiation present when the ground has zero albedo (completely absorbing ground), and the diffuse ground/sky irradiance is that amount added to the total diffuse irradiance when the ground albedo is not zero.

Figures 3-6 through 3-9 present comparisons of the global irradiance at sea level in the USS atmosphere from all of the models as well as comparisons of the three components of the global irradiance. For this atmospheric model, the Bird, Hoyt, and Monte Carlo models produce very similar results. The model of Atwater and Ball significantly underestimates the diffuse sky irradiance, and the Watt model overestimates the diffuse sky irradiance. The results of the Davies and Hay model would have shown much better agreement with the Monte Carlo results if a more reasonable value of the aerosol transmittance had been used. The Bird model Rayleigh transmittance was used in the Davies and Hay model.

It is instructive to examine the relative magnitude of each component. For a solar zenith angle of zero (the sun directly overhead), the direct component provides approximately 81% of the total, the diffuse sky approximately 17%,

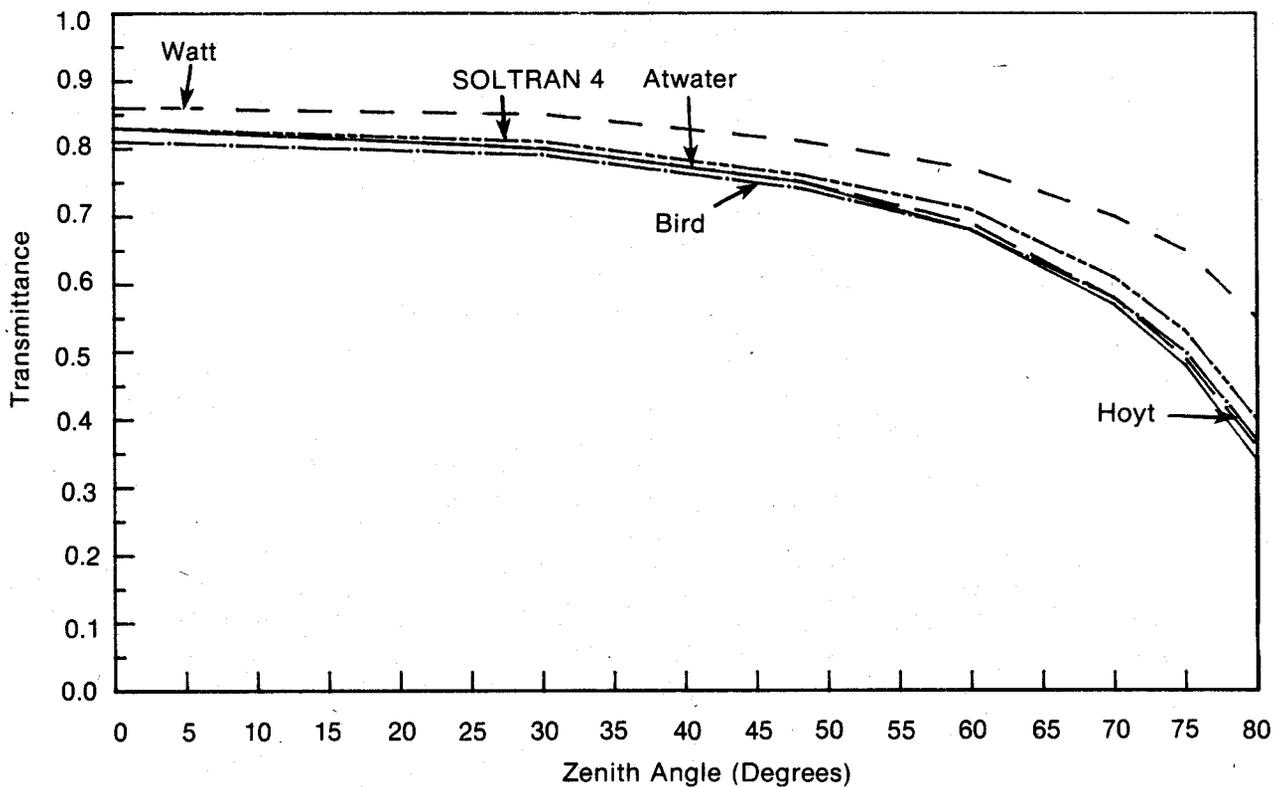

Figure 3-2. Aerosol Transmittance - USS Atmosphere (23-km-Visibility Aerosol)

**Figure 3-9. Diffuse Ground/Sky Insolation – USS Atmosphere (23-km-Visibility Rural Aerosol, Albedo = 0.2)**

and the diffuse ground/sky approximately 2%. The calculations are for a turbidity of 0.27 at 0.5- $\mu\text{m}$  wavelength and a ground albedo of 0.2.

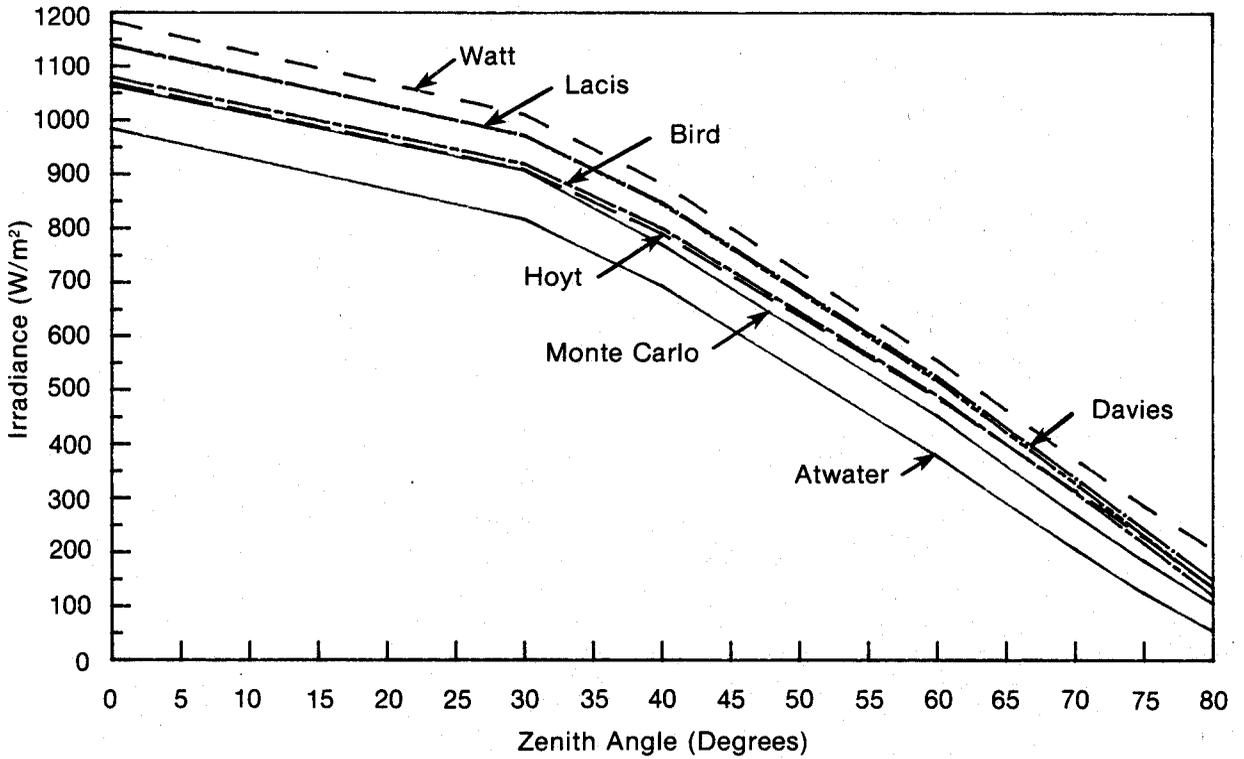

In Figures 3-10 through 3-13, a similar set of plots is presented for the MLS atmospheric model with an atmospheric turbidity of 0.27 at 0.5- $\mu\text{m}$  wavelength and a ground albedo of 0.8. The larger ground albedo increases the diffuse ground/sky component by a factor of four. It is evident that the simple models begin to deviate from the Monte Carlo result for the diffuse ground/sky component. However, since this component is so small, the global result is still in close agreement. The relative agreement of the results from the different models is nearly the same as with the USS atmosphere. This is principally because the aerosol model is identical in both models.

Finally, a comparison is made of the models for the MLS atmosphere with the Haze L aerosol model of Dave [17]. The Dave atmosphere modeled here consists of 15 homogeneous layers instead of the 32 exponentially varying layers that were used in the previous MLS atmosphere. In addition, the Haze L aerosol model is significantly different from the rural aerosol model used previously. Not only are the particle size distributions and complex indices of refraction different, but most importantly the number density of the aerosol as a function of altitude is very different. The turbidity of this model is 0.0996 instead of the 0.266 used previously in the vicinity of 0.5- $\mu\text{m}$  wavelength. Calculations with SOLTRAN 4 show that a turbidity of 0.0996 in the rural aerosol model corresponds to a sea level visibility of nearly 250 km. This is an extremely clear atmosphere. Figures 3-14 through 3-17 illustrate the comparison results for this atmospheric model.

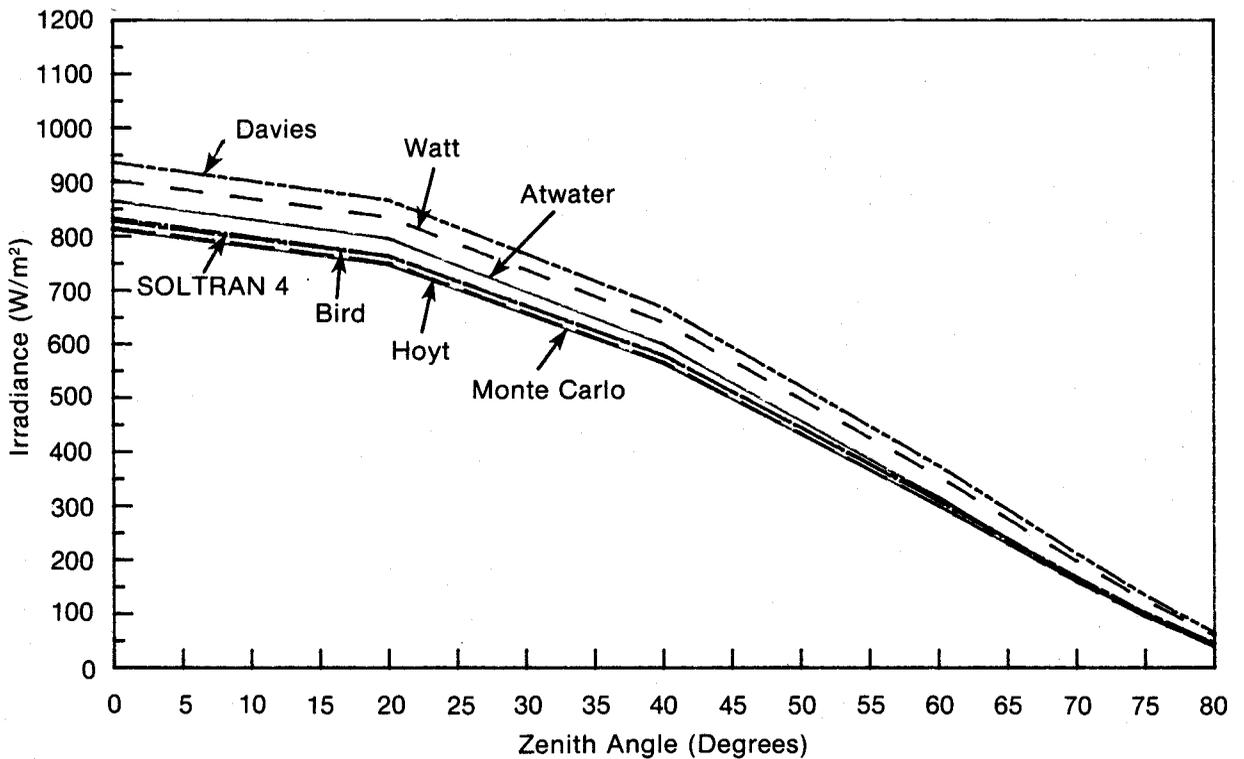

It is readily apparent from the results shown in Figs. 3-14 through 3-17 that the Atwater and Ball model is based on a very clear atmosphere, since it agrees much better with the Dave data. Similarly, the aerosol parameter,  $K = 0.91$ , used in the Davies and Hay model is for a very clear atmosphere. The Lacis and Hansen model appears to be in slightly closer agreement with this clear atmosphere also, but it does not have provisions for changes in turbidity.

The clear sky diffuse irradiance of the Atwater and Ball model as shown in the figures presented here may be slightly lower than the model intended because of the way the calculations were performed. This model is really composed of two separate models: one for the direct irradiance and one for the global irradiance. The clear sky diffuse irradiance was obtained by running the model for a ground albedo of zero and then subtracting the direct horizontal from the global. If the direct horizontal irradiance is slightly high, as it appears to be, then the diffuse term would be slightly lower than expected. The real evaluation of this model should be made on the global horizontal irradiance.

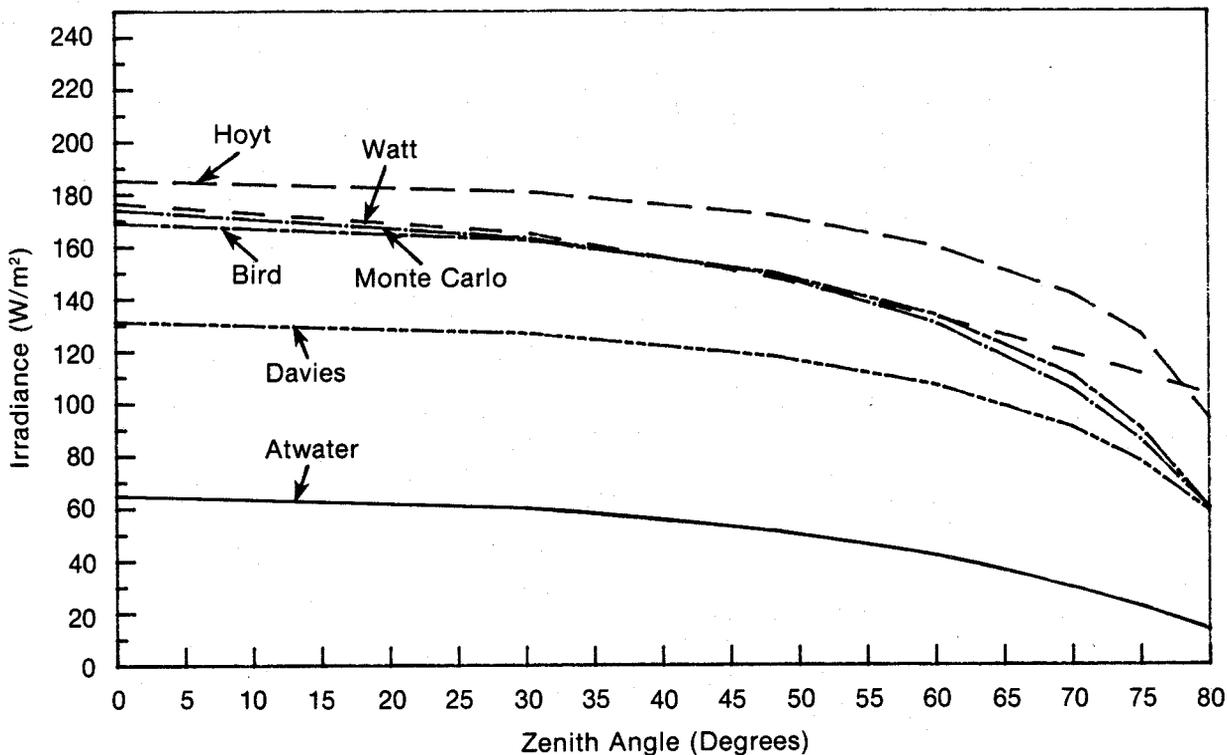

It will be noted in Fig. 3-14 that there is a slight difference between the Monte Carlo global and the spherical harmonic global results of Dave (~3.6% at a zenith angle of 0). Figure 3-15 shows that a large fraction of this difference is in the direct component. Since the direct component of the Monte Carlo code is deterministic in nature rather than statistical, these differences are most likely due to differences in the molecular absorption coefficients used and the band absorption models used. Dave used an older set

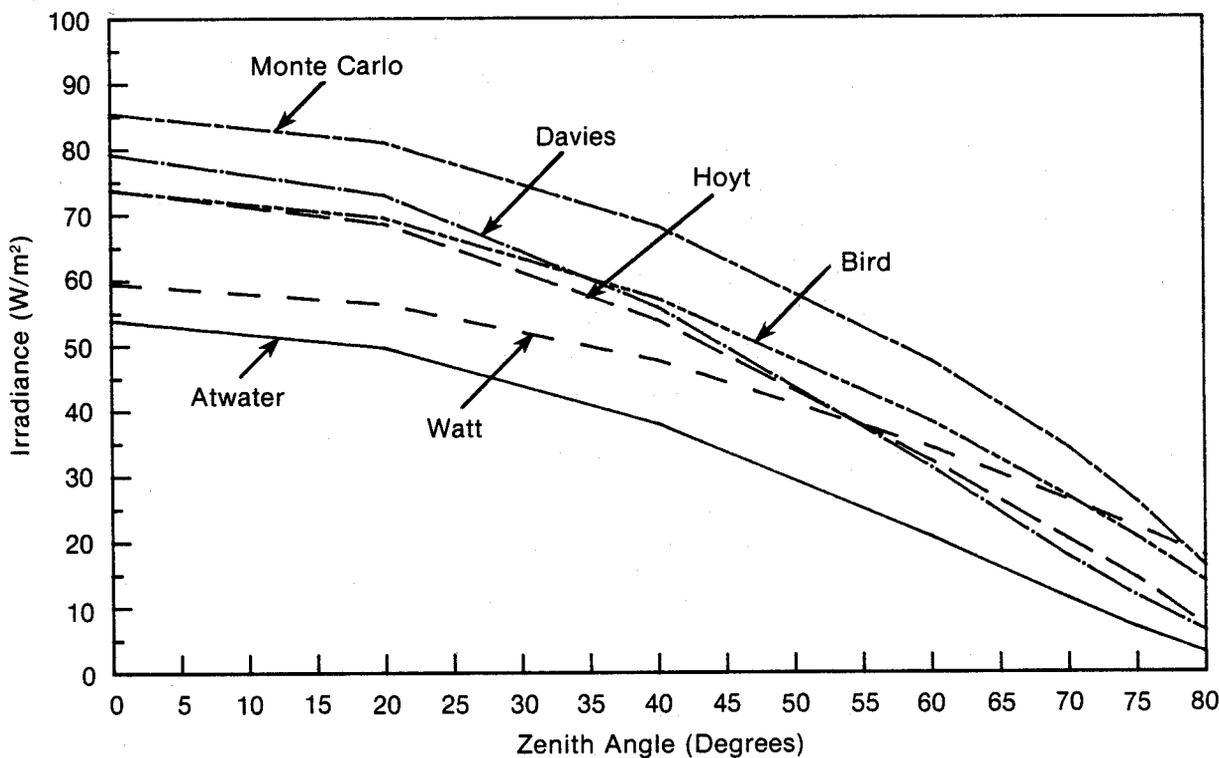

**Figure 3-10. Total Insolation – MLS Atmosphere (23-km-Visibility Rural Aerosol, Albedo = 0.8)**

 (Albedo = 0.2)

of molecular absorption coefficients from AFGL than was used in the Monte Carlo code [20]. Figure 3-18 is a comparison of the spectral direct irradiance for these two codes. It is evident that there are some weak absorption bands present in the Monte Carlo code that are not present in the spherical harmonics code, and the shape of some of the bands is significantly different for the two codes. SOLTRAN 4 is based on the same absorption data that Dave used, and similar differences in the direct normal irradiance occur between SOLTRAN 4 and the Monte Carlo code. These differences are shown in Fig. 3-19, which has 31 more data points in the Monte Carlo results than in Fig. 3-18. This increase in the number of data points increases the apparent spectral resolution. The SOLTRAN 4 code provided approximately 600 data points in this figure. Our conclusion is that most of the differences in the results from the rigorous codes are due to differences in the molecular absorption coefficients used.

A final observation is that many of the simple models have been based on actual measured data rather than comparison to rigorous models. This fact can make a difference in the direct normal irradiance or the diffuse irradiance but should not affect the total irradiance. The reason for this is that pyrheliometers measure the irradiance in a 5.8-degree field-of-view, which includes some diffuse or circumsolar irradiance. The rigorous codes include only the direct normal irradiance with no circumsolar. This means that the direct normal irradiance calculated with the Bird model will slightly underestimate the irradiance measured by a pyrheliometer. On a normal clear day, one is talking about less than a 1% underestimation. Let us reiterate that the total insolation should agree.

## SECTION 4.0

### SUMMARY AND CONCLUSIONS

Five simple broadband models for clear sky global horizontal insolation have been compared with the spectrally integrated results from three rigorous spectral codes. As a part of this comparison, a sixth simple broadband model has been formulated. This sixth model, designated the Bird model, uses parts of the formalisms from the other simple models and has been fine-tuned to provide good agreement with the rigorous codes. The Bird model was constructed so that readily available meteorological data could be used in it. It is based entirely on algebraic expressions rather than look-up tables, which greatly simplifies the use of the model.

The comparison of the results from each of the simple models with the results of the rigorous codes indicates the following:

- The Atwater and Ball model is applicable to extremely clear atmospheric conditions with an atmospheric turbidity (base e) near 0.1- at 0.5- $\mu\text{m}$  wavelength. For turbidities near 0.27, this model underestimated the global irradiance by approximately 8% for air mass 1 (AM1). This model is extremely simple but does not have a good method of treating aerosol transmittance.
- The Watt model is relatively complicated and appears to overestimate the global insolation for AM1 conditions by approximately 7%. This is a complete model based on meteorological parameters. However, the upper air turbidity required in this model is not readily available.
- The Hoyt model provides excellent agreement with the rigorous codes. However, its use of look-up tables and the requirement to recalculate transmittance and absorptance parameters for modified air mass values causes this model to be relatively difficult to use.
- The Lacis and Hansen model is extremely simple. It tends to overestimate the global irradiance by approximately 8% at AM1, and it has no provisions for calculating direct irradiance.
- The Davies and Hay model could possibly provide good agreement with the rigorous codes. However, it uses a look-up table for the Rayleigh scattering transmittance term and does not have a good method for treating aerosol transmittance. The aerosol transmittance through a vertical path used by Davies and Hay for southern Ontario ( $K = 0.91$ ) is for an extremely clear atmosphere.
- It is hoped that the rigorous codes and accurate simple models will provide results that will agree within  $\pm 5\%$  with quality experimental data on clear days. Cloudy days are much more difficult to model accurately, and clouds can have the greatest effect on the total irradiance. Models that address cloud influences for irradiance will be examined at a later date.

- It should be recalled that the basis of comparison/evaluation of the simple models is the much more rigorous radiative transfer codes--as opposed to a comparison with actual data. Because of a lack of suitable, high-quality data, comparisons with actual data are impossible at this time. The greatest deficiency has been the lack of meteorological measurements accompanying good insolation data. However, efforts\* are currently underway at SERI and several universities to provide such data. As this data becomes available, comparisons and improvements will be made. Until then, it appears that both the Hoyt and Bird simplified models yield results in good agreement with the rigorous techniques. However, the Bird model is more flexible and easily used.

**APPENDIX A**  
**TABULATED MODEL DATA**

Three sets of tabulated data from each simple model are presented here, and each set represents one of the atmospheric models discussed in the main text. The parameters listed at the top of each table are:

- $I_0$  = Solar constant ( $W/m^2$ )
- UW = Precipitable water vapor in vertical path (cm)
- UO = Ozone amount in vertical path (cm)
- PR = Surface pressure (mb)
- TAU5 = Turbidity at 0.5- $\mu m$  wavelength
- TAU38 = Turbidity at 0.38- $\mu m$  wavelength
- RS = Ground albedo
- TEMP = Surface temperature (K)
- CONST = Constant K used in BIRD model
- BA = Forward to total scattered irradiance ratio
- TAUB = Broadband turbidity

The parameters at the top of each column of data are self-explanatory for the transmittance and absorptance terms. The remaining parameters are:

- DIRH = Direct horizontal irradiance ( $W/m^2$ )
- DIFSH = Diffuse sky horizontal irradiance ( $W/m^2$ )
- DIFGH = Diffuse ground horizontal irradiance ( $W/m^2$ )
- DTOT = Total or global horizontal irradiance ( $W/m^2$ )

16. Abstract (Limit: 200 words) A detailed comparison was made between five simple broadband models for clear sky global insolation. Compared models were those of Atwater and Ball, Davies and Hay, Watt, Hoyt, and Lacis and Hansen. A sixth simple model, called the Bird model, has been formulated by using parts of these five models and by comparison with the results from three rigorous radiative transfer codes. All of the simple models provide results that agree within <10% with the three rigorous codes when the sun is in the zenith position. The Bird and Hoyt models agree within 3% with each other and with the results of the rigorous codes. However, the Bird model is easier to implement and has broader application than the Hoyt model.
