**Which device(s) are causing oscillations? Existing Solution: Let's just turn off wind and PV.**

# New Challenges in Power System Stability Analysis

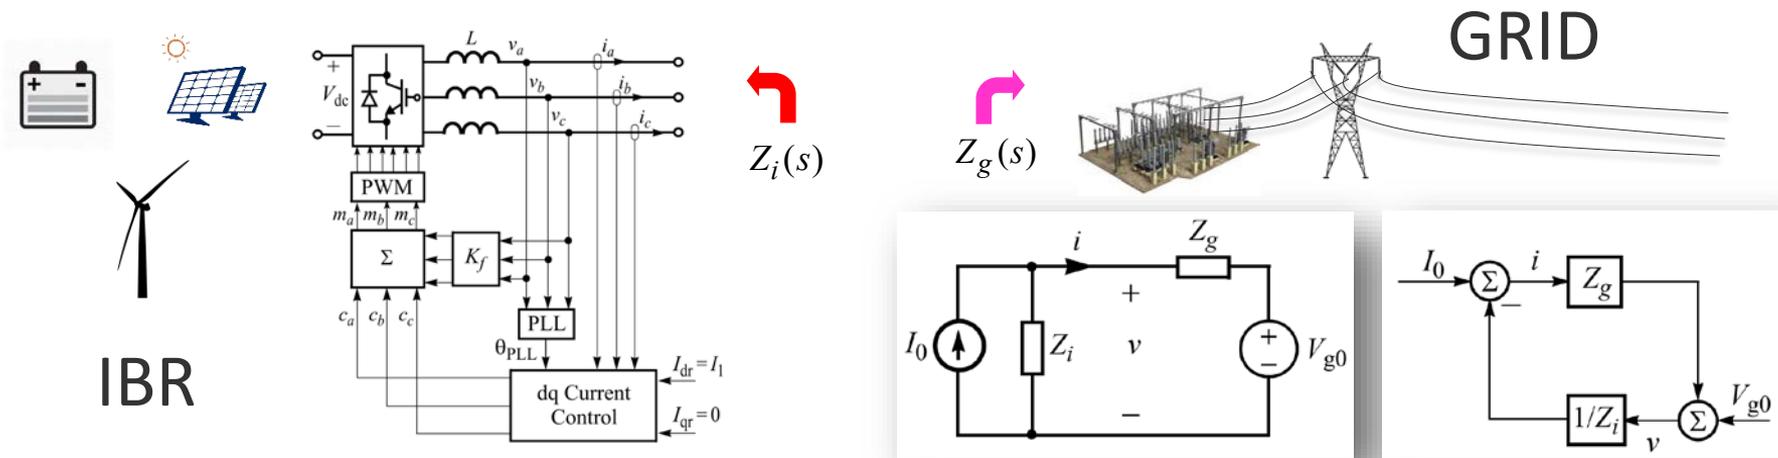

- Controls of power electronics are fast, complex, and non-standardized, resulting in control interactions, oscillations, and instabilities.
- As more power electronic-based resources are added to the grid, this will become an increasing problem unless there is a way to characterize their responses.
- Data-driven tools are needed for analyzing the stability of modern power systems.

# Impedance-Based Stability Analysis

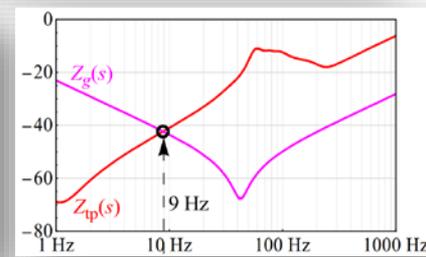

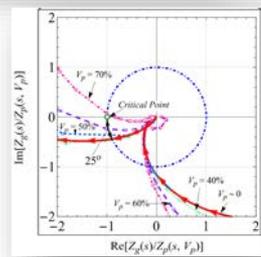

---

# Existing Impedance-Based Stability Criterion

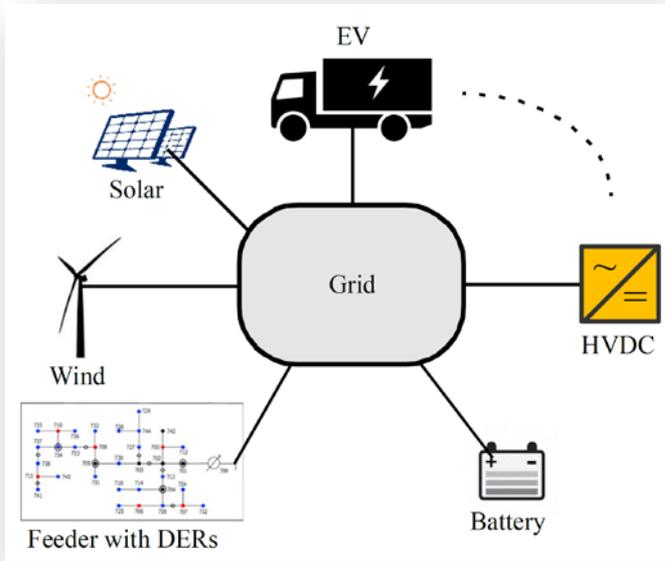

- Loop Gain:  $Z_g(s)/Z_i(s)$
- **Fundamental Premise:** IBR and the Grid are Separately Stable

$$N = Z - P$$

# Scaled Version of the Existing Stability Criterion

- Loop Gain:  $\mathbf{Z}_g(s) \cdot \mathbf{Y}_i(s)$
- **Fundamental Premise:** All IBRs and the Grid are Separately Stable

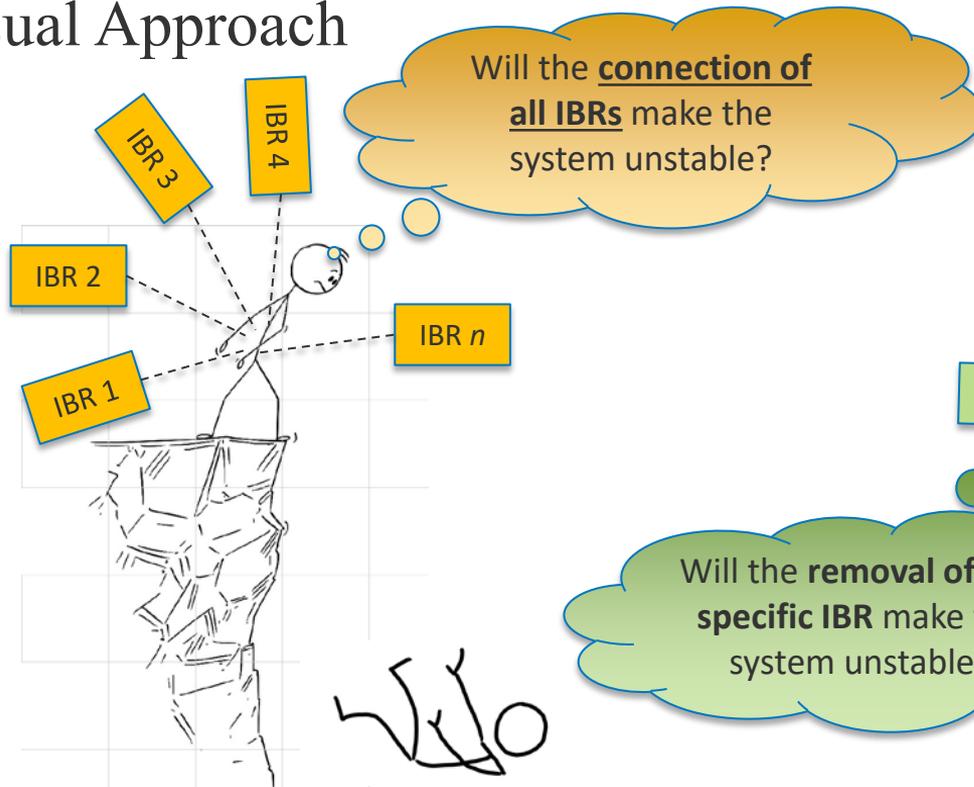

- $\mathbf{Y}_i(s)$  is the diagonal matrix with admittances of IBRs at diagonal elements
- $\mathbf{Z}_i(s)$  is the full matrix capturing the impedance of the grid (rest of the power system) from POIs of the IBRs

$$N = Z - P$$

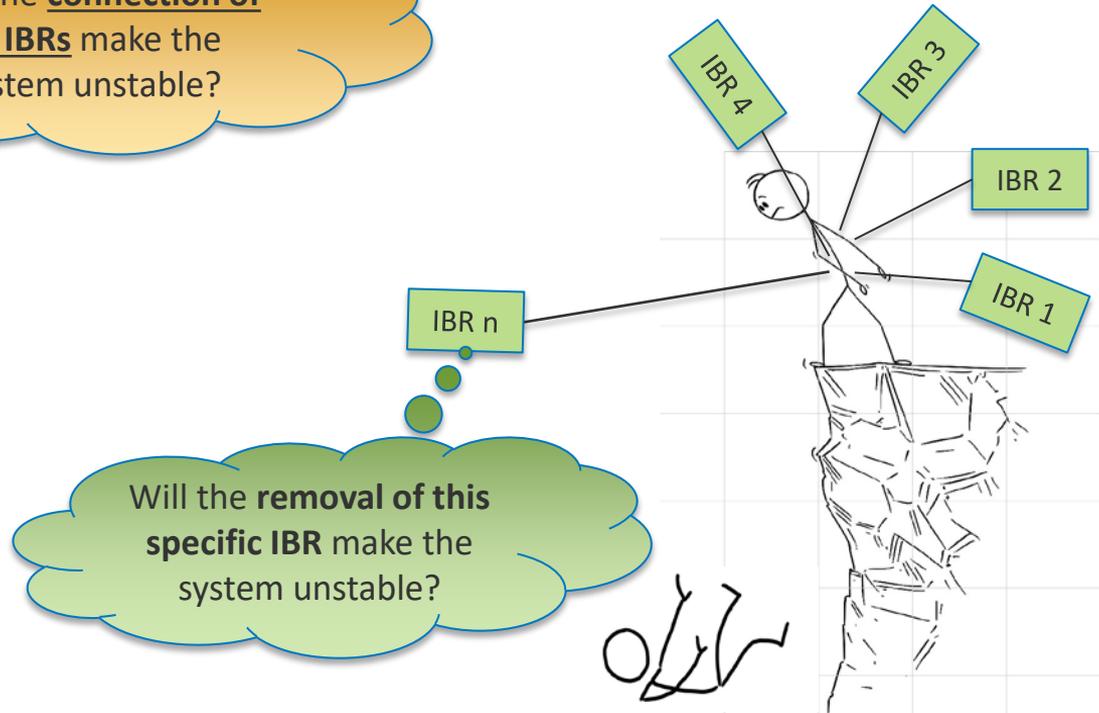

- **Approach:**  $P$  is zero, find out  $Z$  by counting the number of encirclements  $N$  of the critical point by the Nyquist plot of loop gain  $\mathbf{Z}_g(s) \cdot \mathbf{Y}_i(s)$ 
  - System is unstable if  $Z \neq 0$

# Reversed Impedance-Based Stability Criterion

## Usual Approach

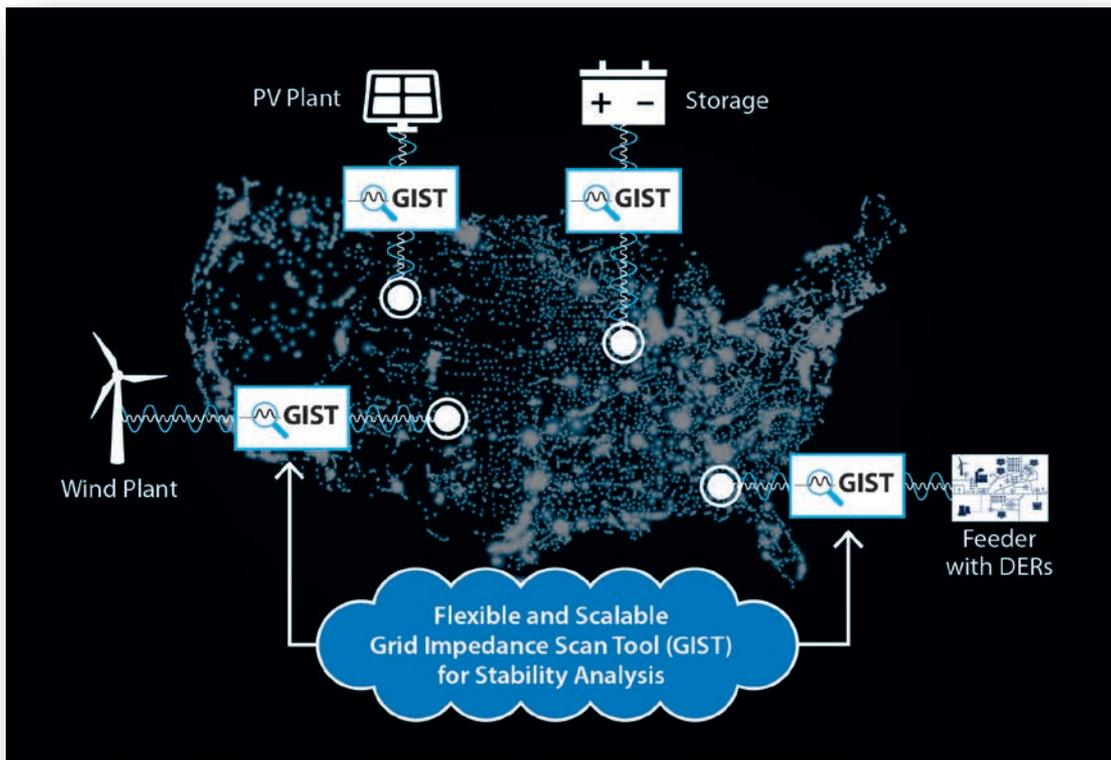

## Reversed Approach

# Grid Impedance Scan Tool (GIST)

---

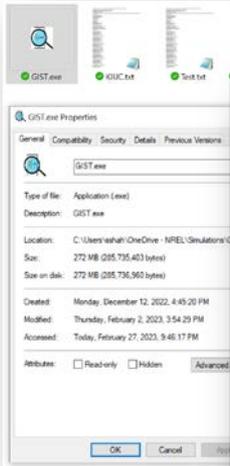

# GIST Software Capabilities

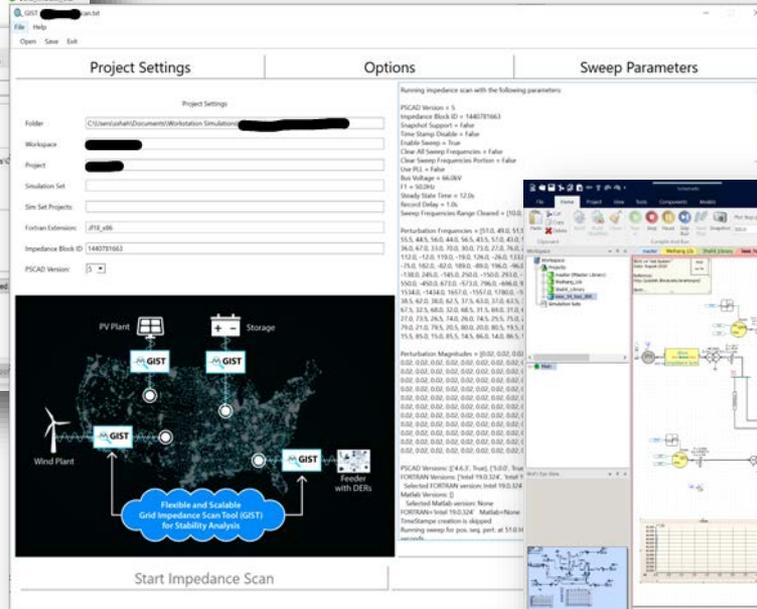

- GIST scans IBR and grid impedances in PSCAD across wide frequencies
- GIST evaluates the impact of the IBR on grid stability using impedance Scans
- Fully automated scans
- Scan when the fundamental frequency is not 60 Hz
- Output in all reference frames: stationary, rotating (dq), power-domain

# GIST Software is Available for Licensing

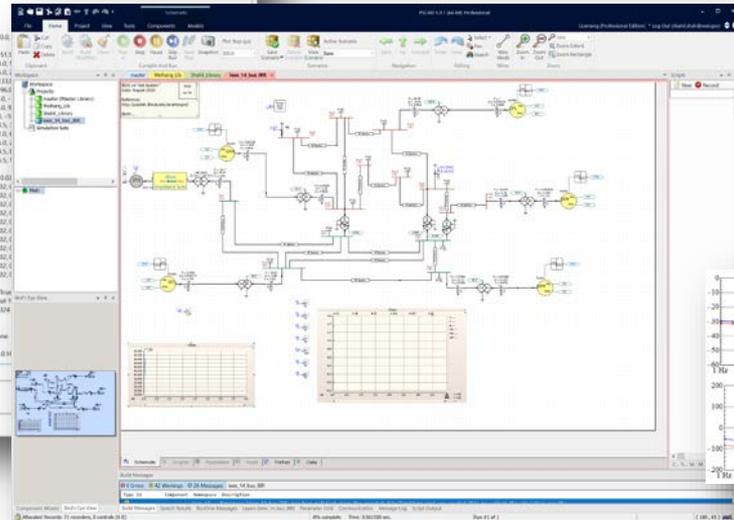

Executable File

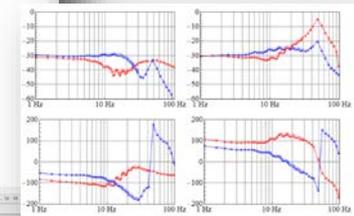

Graphical User Interface

Interface with PSCAD Software

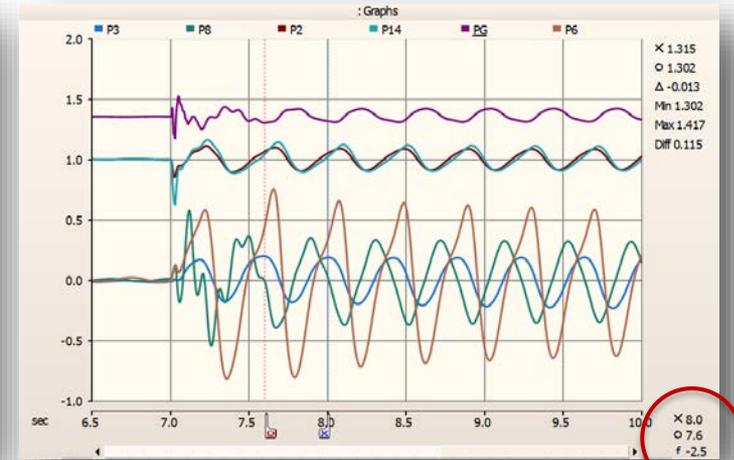

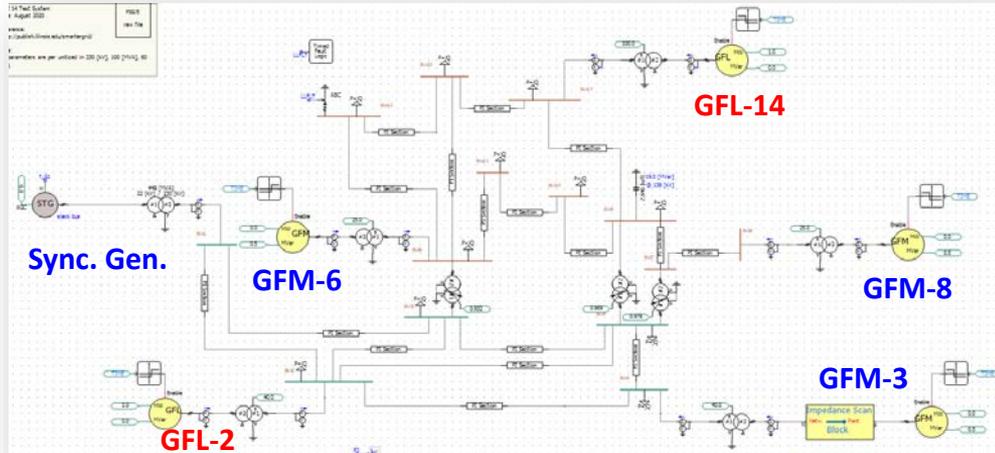

Output

# 14-Bus System with High Levels of IBRs

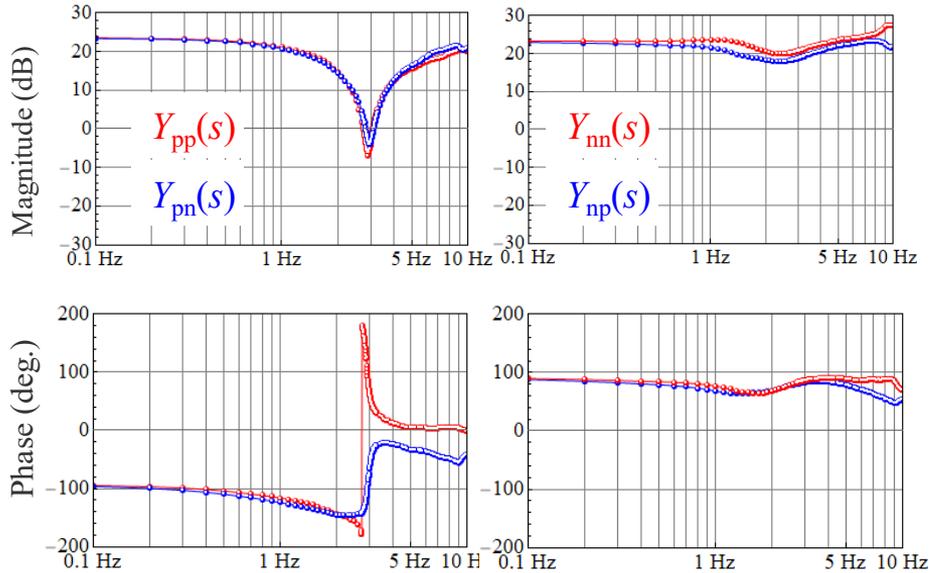

1 Sync. Generator (224 MW); 3 GFM Inverters (90 MW); 2 GFL Inverters (140 MW)

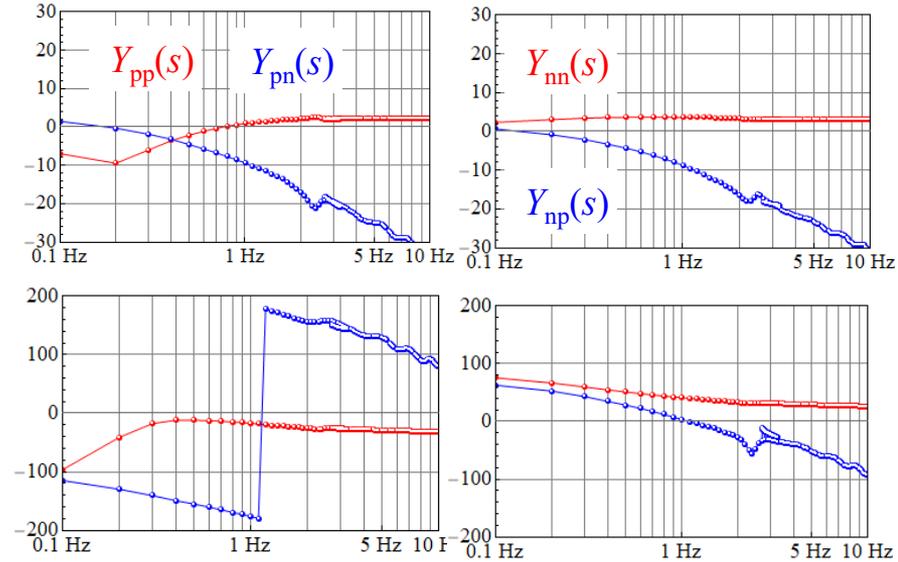

- How to identify the frequency and damping of the 2.5 Hz mode?
- What is the impact and participation of selected IBRs on the 2.5 Hz mode?
- How to estimate the minimum GFM capacity required for stable operation?

# 19.5 Hz Oscillation Event in Kauai (Hawaii, US)

---

# 19.5 Hz Oscillation Event in Kauai System

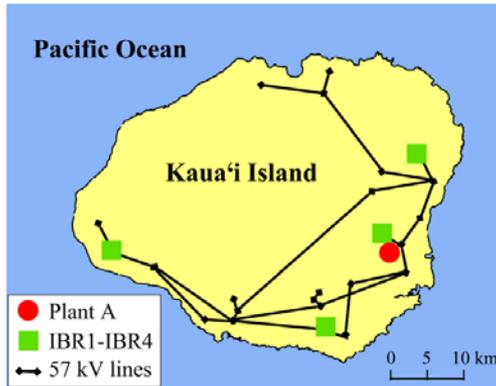

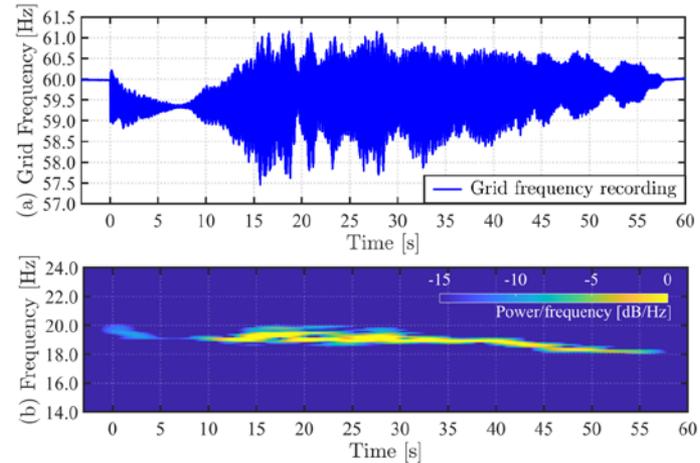

TABLE I  
KIUC GENERATION MIX  
BEFORE AND AFTER EVENT

Time	$t = 0^-$ s	$t = 60$ s
Plant A	60.6%	0.0% ↓
IBR1	4.1%	14.0% ↑
IBR2	4.6%	21.0% ↑
IBR3	0.0%	14.0% ↑
IBR4	4.1%	23.0% ↑
Biomass	13.7%	14.0% ↑
Hydros	13.0%	13.0% —

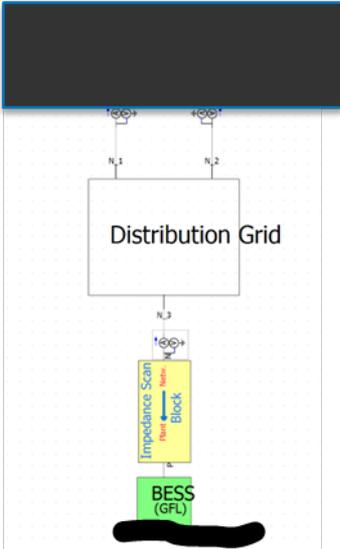

- The event started on Nov. 21, 2021, after tripping of a large generator supplying around 60% of the load

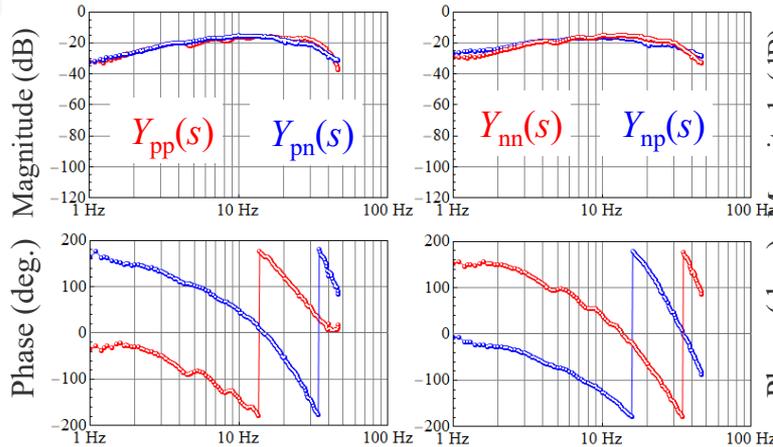

– **Question: What triggered the 19.5 Hz oscillations?**

- Source: S. Dong, et. al., “Analysis of November 21, 2021, Kaua’i Island Power System 18-20 Hz Oscillations” Link: <https://arxiv.org/pdf/2301.05781.pdf>

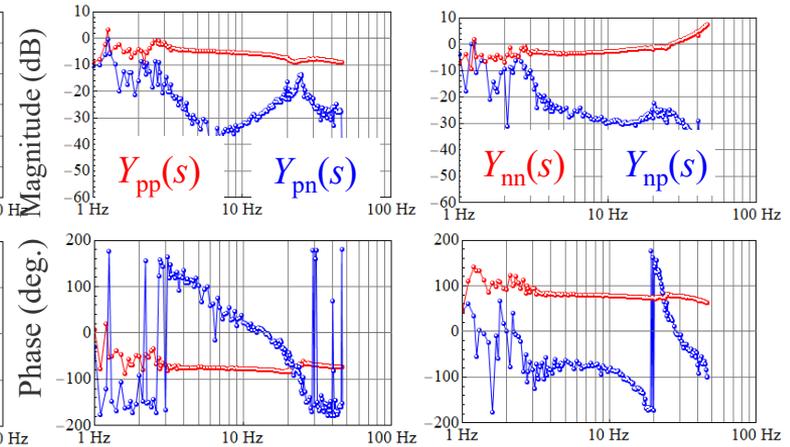

# Scan at Plant X

## Plant Admittance

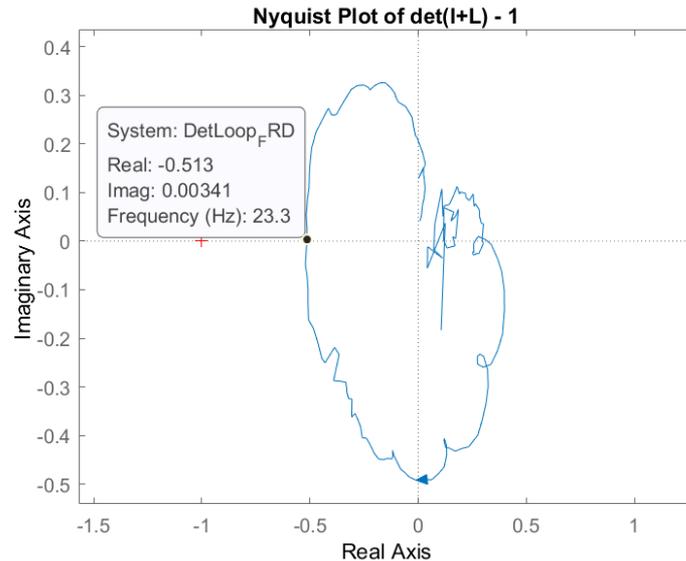

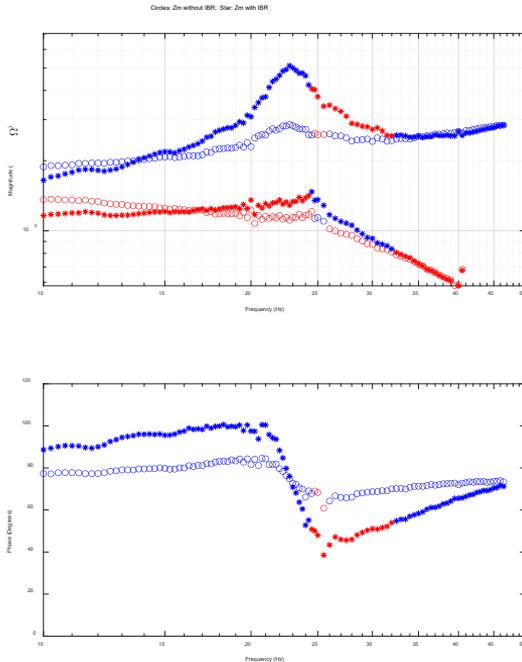

## Network Admittance

- Frequency scans are performed at the X plant by inserting GIST tool between the X plant and the rest of the network

# Analysis at Plant X

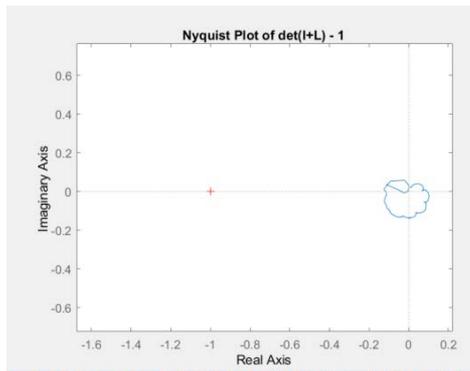

- Modal Impedance with (\*) and without (o) the X Plant
- Nyquist Plot of determinant of  $[I + Z_{\text{netw.}}(s)/Z_{\text{plant}}(s)] - 1$

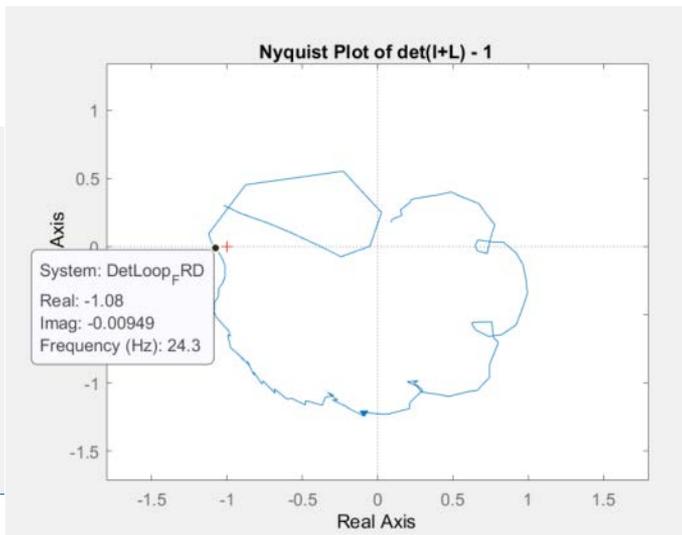

- **Analysis Result:**
  - An underdamped resonance mode at 23 Hz is identified
  - The damping of the mode is 9.8% with the X plant and it is 50% without the X plant
  - X reduces the damping of the mode by as much as 40%

# Plant X in SMIB Format: Impedance Analysis

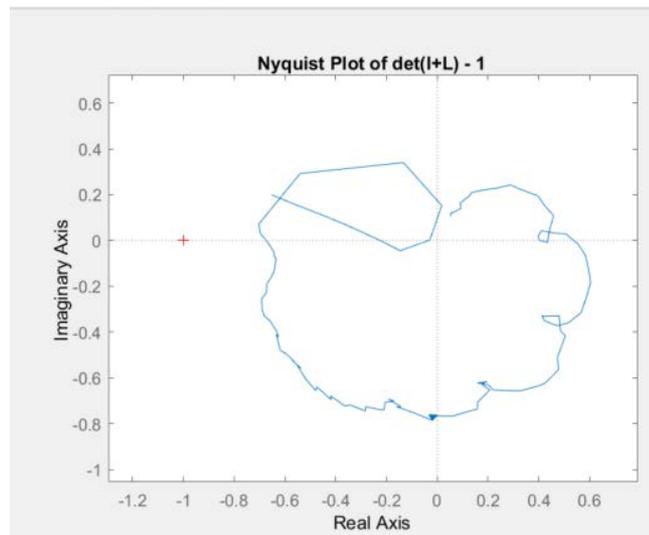

- SCR = 30
  - Impedance analysis predicts stable operation

- SCR = 3
  - Impedance analysis predicts instability at 24 Hz

- SCR = 5
  - Stable but with low margin around 24 Hz

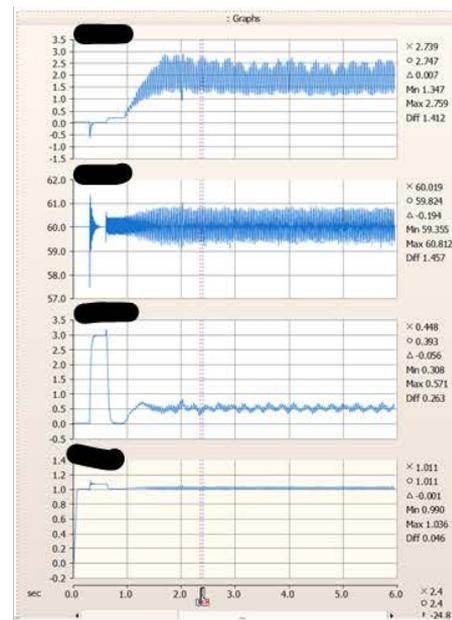

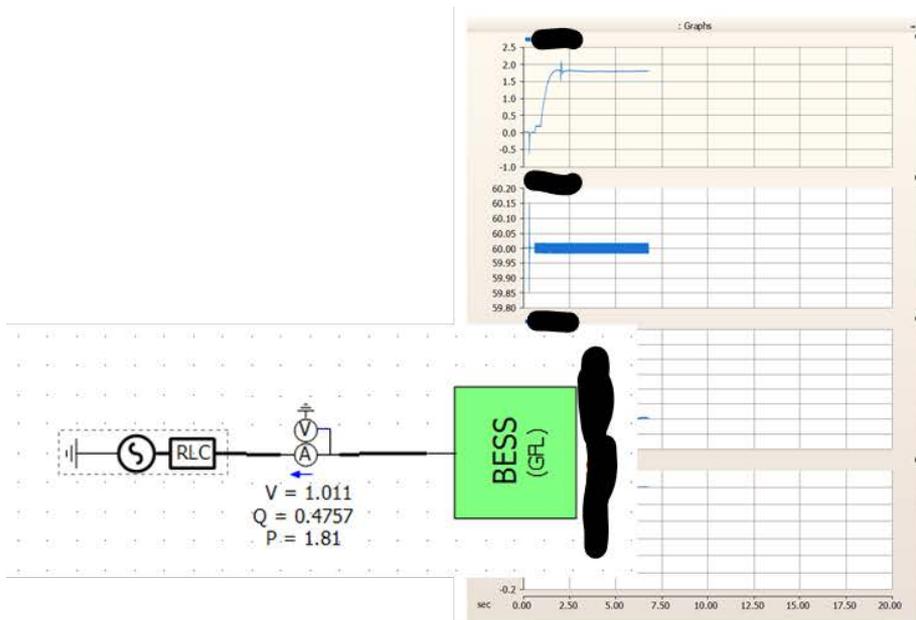

# Operation of Plant X in SMIB Format

• SCR = 30

• SCR = 3

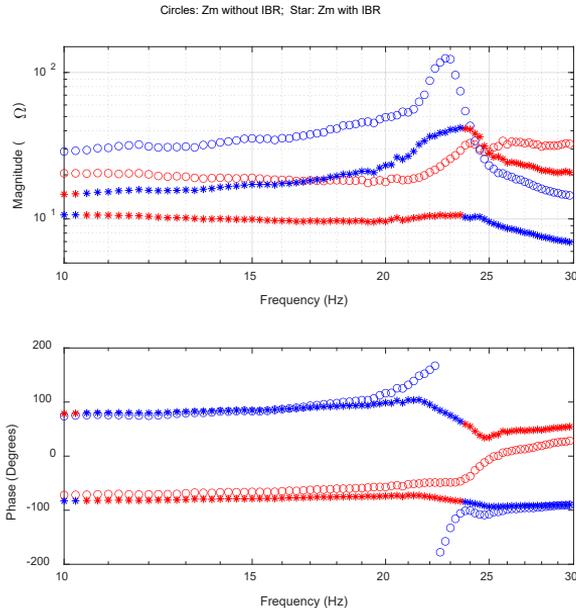

• SCR = 5

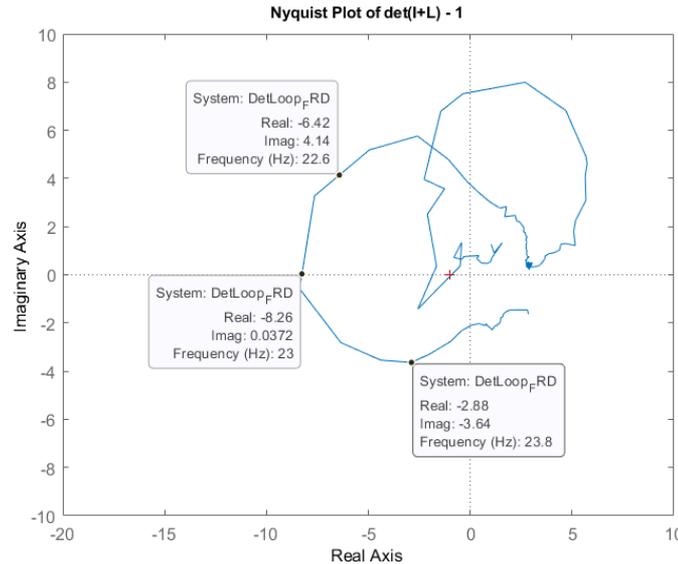

- Answer: The oscillations were triggered by the inability of couple of IBR plants to operate with grids with SCR below 3.5 and the loss of grid strength after tripping of a major conventional power plant.

# Analysis at Plant Y

- Modal Impedance with (\*) and without (o) the Y Plant

- Nyquist Plot of determinant of  $[I + Z_{netw.}(s)/Z_{plant}(s)] - 1$

- **Analysis Result:**
  - An underdamped resonance mode at 23 Hz is identified
  - The mode is unstable without the Y plant
  - The Y plant holds the system stable

# 19 Hz Oscillations in AEMO (Australia)

---

# 19 Hz Oscillations in AEMO Network

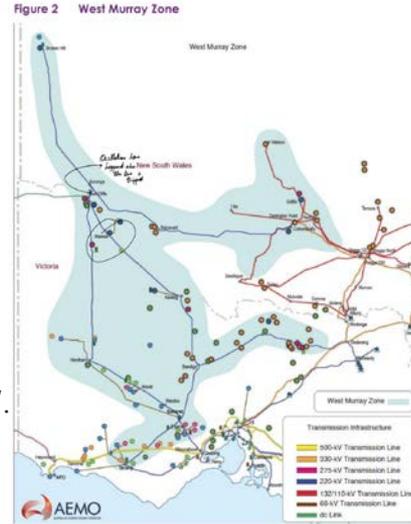

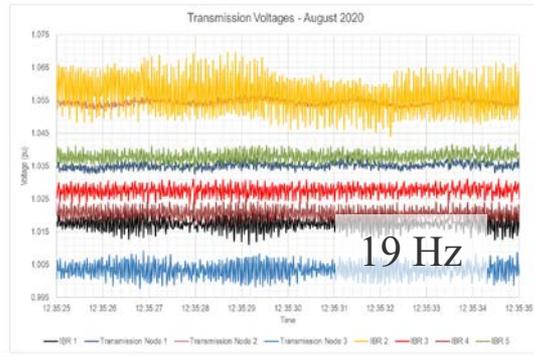

Figure 7 Red Cliffs 220 kV RMS voltage oscillations on 4 September 2020 with Harsham SVC in manual mode

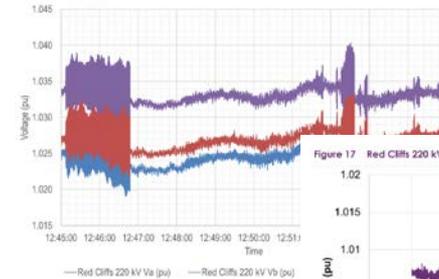

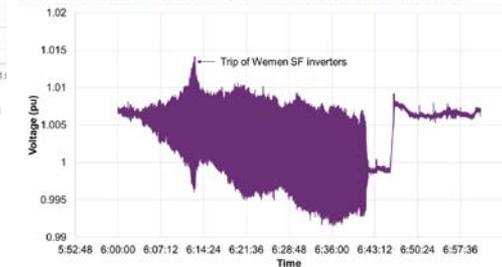

Figure 17 Red Cliffs 220 kV RMS voltage oscillations, 0600 hrs to 0700 hrs on 16 November 2021

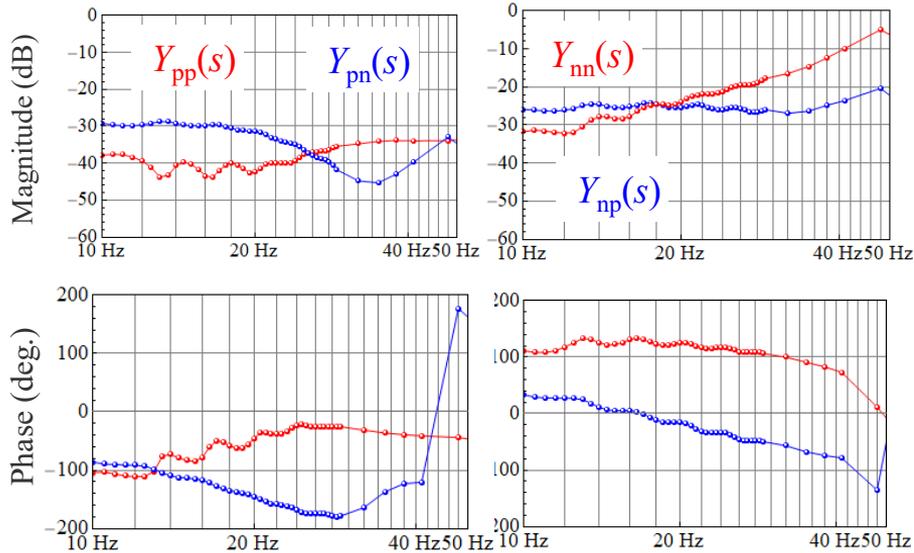

Source: Jalali, et. al. (AEMO), CIGRE 2021.

Source: West Murray Zone Power System Oscillations, 2020-2021.

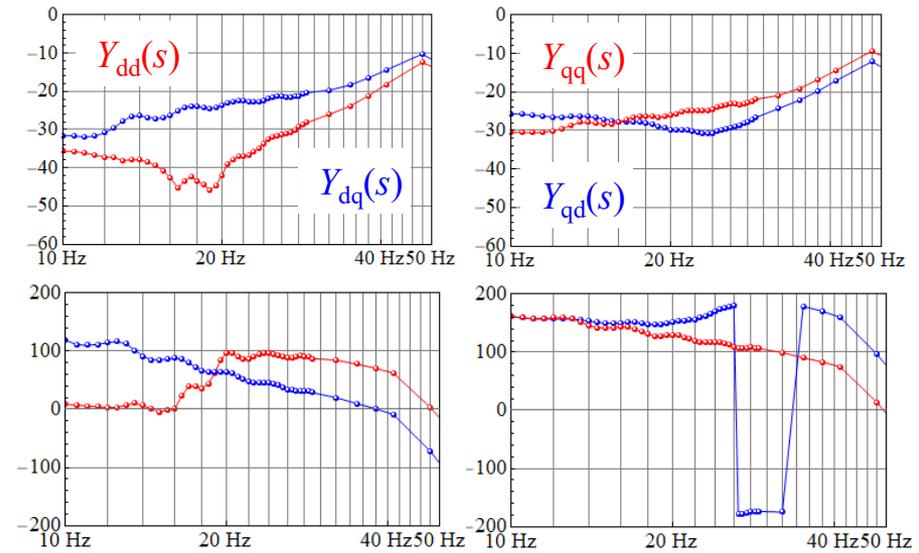

- AEMO (Australia) has experienced 17-20 Hz oscillation events in the West Murray Zone
  - Question: What is triggering these oscillations?

# Plant X: Operation Condition 1

## Sequence Admittance

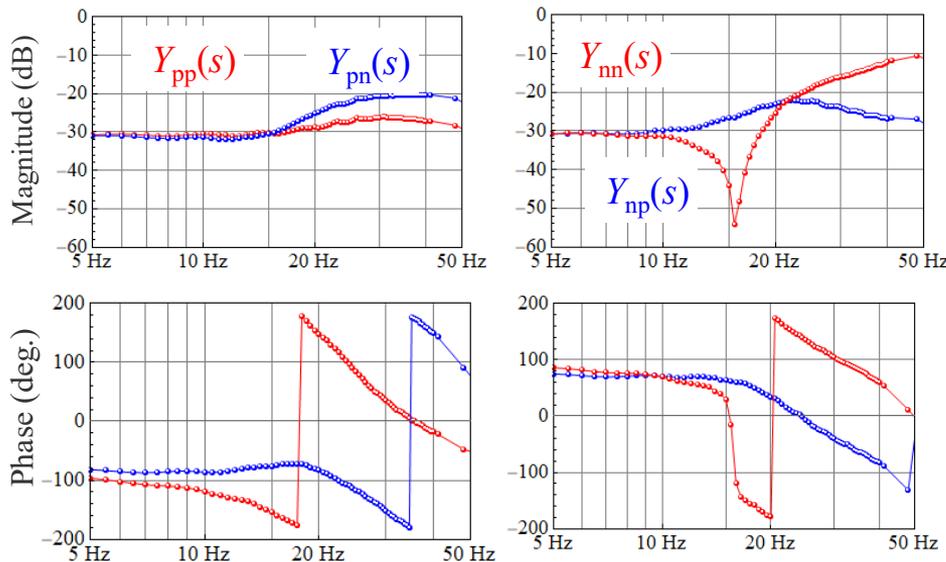

## DQ Admittance

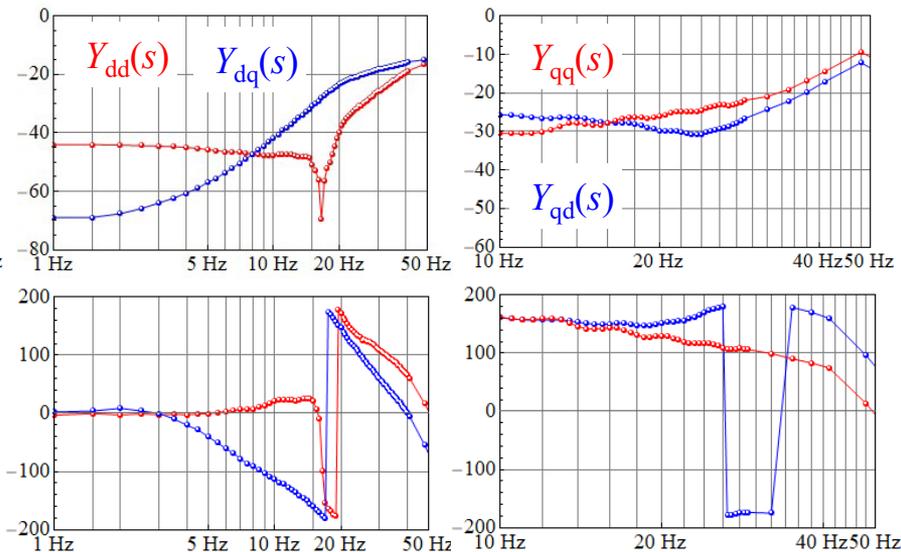

# Plant X: Operation Condition 2

## Sequence Admittance

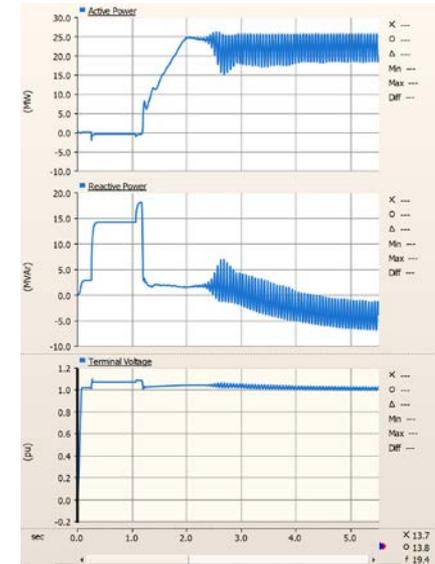

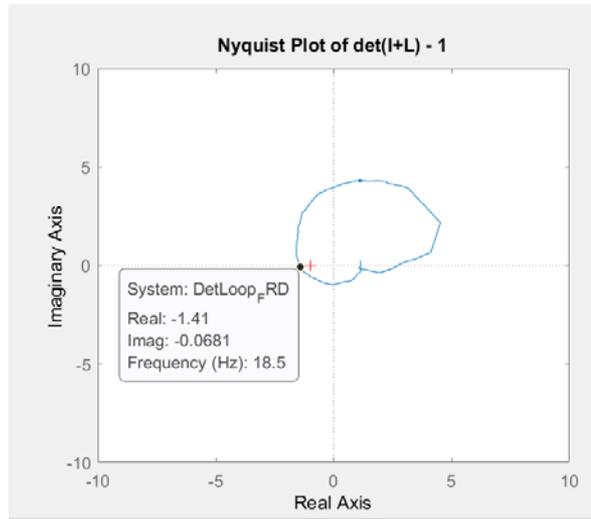

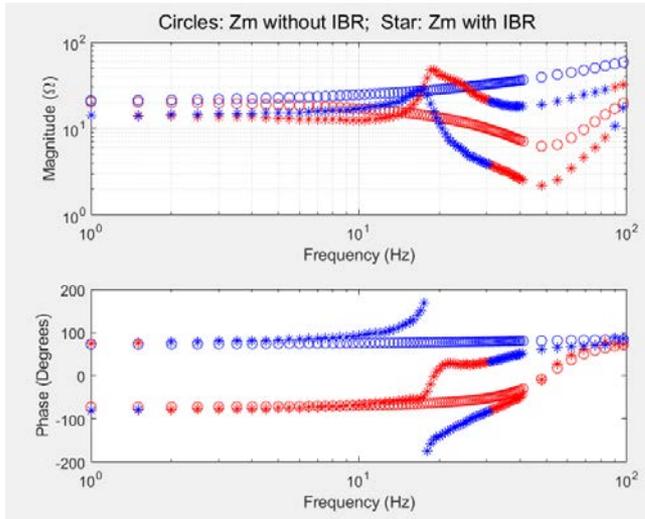

## DQ Admittance

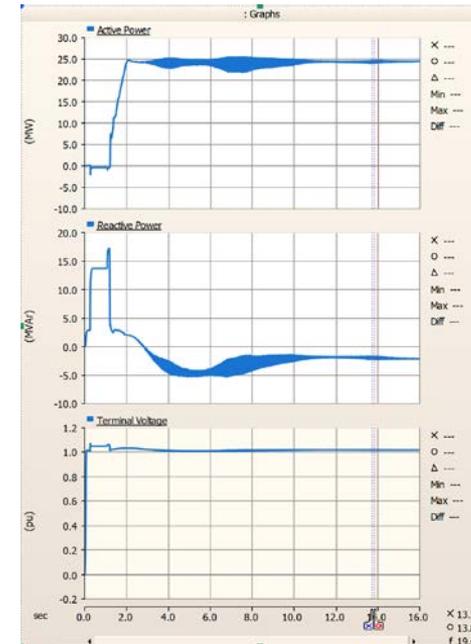

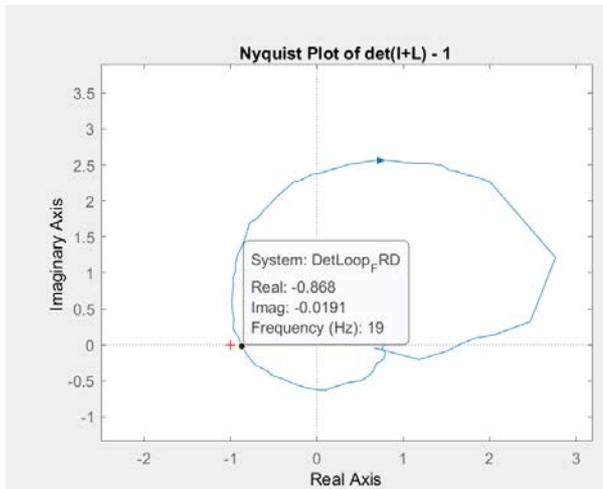

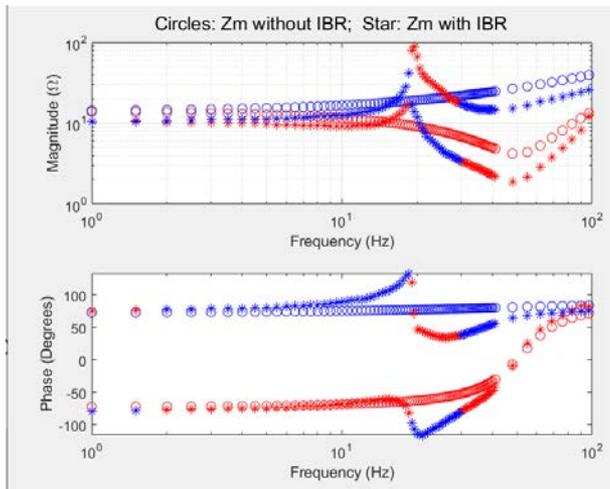

- Severe resonance at 17 Hz

# Stability Analysis for SCR 2.1 and X/R 3.2

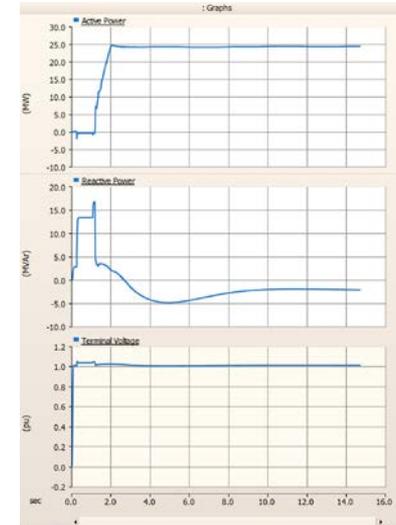

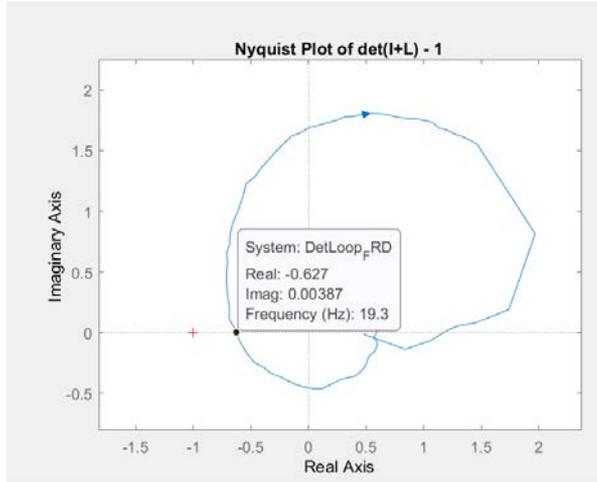

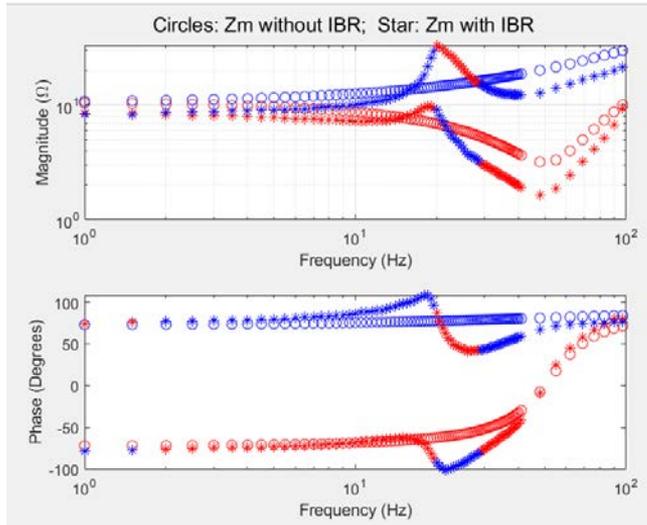

- Plant is unstable stable – confirmed by time-domain simulations (17.4 Hz)

# Stability Analysis for SCR 3.1 and X/R 3.2

- Plant is marginally stable – confirmed by time-domain simulations (19.4 Hz)

# Stability Analysis for SCR 4.1 and X/R 3.2

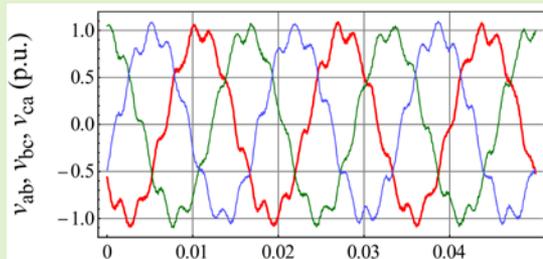

- Plant is stable with low stability margin – Plant still has highly underdamped resonance, but it will not excite oscillations in the absence of any disturbance
- Answer: Certain IBR plants have an unusual resonance mode around 17-20 Hz during certain operating conditions

# Hardware Impedance Measurement System for Utility Scale Inverters and Wind Turbines

Impedance Responses show Better Damping for GFM Control Mode

# Making Inverters Sing Using GIST

The image shows a person in silhouette pointing at a presentation slide. The slide is titled "Power Systems Can Sing to the Same Tune" and features a musical score for a piece of music. The score is written on a grand staff with treble and bass clefs. The notes are numbered 1 through 7, and the chords are labeled Eb, Am, Dm, and Eb. The frequency  $F_5 = 698\text{Hz}$  is indicated. Below the score are four graphs showing the power system's response to the music. The graphs are labeled "2022\_06\_06\_04\_03\_26\_FIG\_17\_FIG\_Music" and "2022\_06\_06\_04\_03\_26\_FIG\_18\_FIG\_Music". The graphs show the power system's response to the music, with the x-axis representing time and the y-axis representing power. The graphs show a clear correlation between the music and the power system's response. The slide also includes the text "run impedance scan" and "National Renewable Energy Lab".

**Power Systems  
Can Sing  
to the Same Tune**

As a way to help people understand a frequency scan, we created a movie of how inverters can be made to play tunes by scanning frequencies in a certain order.
