Pumping system control valve inefficiencies in plant processes offer opportunities for energy savings and reduced maintenance costs. Valves that consume a large fraction of the total pressure drop for the system or are excessively throttled can be opportunities.

\[ H_L = K \times \left( \frac{v^2}{2xg} \right) \]

where

- \( H_L \) = the fitting head loss, in feet
- \( v \) = fluid flow velocity, in feet/second
- \( g \) = the gravitational constant, 32.174 feet/second
- \( K \) = the fitting head loss coefficient. For valves, \( K \) is a function of valve type, size, and the percentage of time that the valve is open.

For example, for fluid with a specific gravity of 1, a pressure drop of one pound per square inch (psi) is equal to a head loss of 2.308 feet.

Fluid horsepower = flow rate (gpm) x head loss (ft) x fluid specific gravity / 3,960 (where 3,960 is a conversion factor)

The friction loss and pressure drop caused by fluids flowing through valves and fittings depend on the size and type of pipe and fittings used, the roughness of interior surfaces, and the fluid flow rate and viscosity. Typical ranges of head loss coefficients (\( K \) values) for various fittings are given in the table. Values can vary by 30% to 50% because of variations in pipe size, type of fluid, and other factors. Fitting head losses vary with the square of the fluid flow rate or flow velocity:

\[ H_L = K \times \left( \frac{v^2}{2xg} \right) \]

U.S. Department of Energy — DOE’s PSAT can help you assess pumping system efficiency and estimate energy and cost savings. PSAT uses pump performance data from HI standards and motor performance data from the MotorMaster+ database.

Visit the BestPractices Web site at www.eere.energy.gov/industry/bestpractices to access these and many other industrial efficiency resources and information on training.

### Table 1. Range of Head-loss Coefficients (\( K \)) for Water Flowing Through Various Fittings

<table>
<thead>
<tr>
<th>Fitting Description</th>
<th>K Value</th>
<th>Fitting Description</th>
<th>K value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Globe valve, fully open</td>
<td>3 – 8</td>
<td>Square-edged inlet (from tank)</td>
<td>0.5</td>
</tr>
<tr>
<td>Ball valve, fully open</td>
<td>0.04 – 0.1</td>
<td>Bell-mouth inlet</td>
<td>0.05</td>
</tr>
<tr>
<td>Check valve, fully open</td>
<td>2</td>
<td>Discharge into tank</td>
<td>1</td>
</tr>
<tr>
<td>Gate valve, fully open</td>

Energy Savings Opportunities

Pumping system controls should be evaluated to determine the most economical control method. High-head-loss valves, such as globe valves, are commonly used for control purposes. Significant losses occur with these types of valves, however, even when they are fully open. If the evaluation shows that a control valve is needed, choose the type that minimizes pressure drop across the valve.
Adjustable speed drives (ASDs) are often recommended for pumping systems that have variable flow rate requirements. When systems are being retrofitted with ASDs, the control valve can be removed from the system to eliminate unnecessary pressure drops. The control valve can be replaced with a spool piece or, when isolation capability is desired, a carefully selected low-loss replacement valve.

Figure 1 illustrates the wide variability in frictional head loss as a function of flow rate across three types of fully open, 12-inch valves. Substantial energy and cost savings can be achieved by installing a low-loss valve, such as a butterfly valve. When installing a smaller pump impeller, trimming an existing impeller, or making other pumping system modifications, consider replacing current valves with more efficient ones.

To calculate control valve losses in terms of head, energy, and cost, see DOE’s Pumping System Assessment Tool (PSAT), available online in the Resources section of the ITP BestPractices Web site: www.eere.energy.gov/industry/bestpractices.
