While the development of new physisorption materials with high surface areas prepared from the pyrolysis of high-melt polymers are promising venues to meeting the much sought-after storage targets, our analyses indicate that engineering the self-assembly of novel classes of non-pyrolytic materials from molecular building units into three-dimensional (amorphous) PPN results in the establishment of a new benchmark in performance for hydrogen excess adsorption: 8.5 wt% at 77 K and 60 bar. An important advantage that PPN structural motifs appear to offer over the existing benchmark, MOF-177, lies in their remarkable thermal and chemical stability, which can be attributed to their entirely covalent bonding network. Indeed, PPNs can be handled in an open-air laboratory environment without

impacting their performance. Studies in the future should examine post-synthetic methods of improving the volumetric capacity of these materials, which currently falls short of the MOF-177 benchmark, by examining what effects high-pressure mechanical compaction (i.e., pelletizing) may have on the gravimetric and volumetric capacity of PPN.

Technical Targets

The goal of this project is to prepare a reference document detailing the recommended best practices and limitations in making critical performance measurements on hydrogen storage materials. This reference document will provide a resource to improve the accuracy and efficiency of critical measurements to aid the projects and ultimately the entire program to achieve or exceed the technical storage targets.

In particular this project is focused on the following target related performance measurements:

- Kinetics (Targets: system fill time for 5-kg hydrogen, minimum full-flow rate and start time to full-flow)
- Capacity (Targets: gravimetric and volumetric capacity)
- Thermodynamic Stability (Targets: maximum/minimum delivery pressure of H₂ from tank and impact on capacity and kinetic related targets)
- Cycle-Life Properties (Targets: cycle life and cycle life variation)

FY 2011 Accomplishments

- Modify 2010 Best Practices document with input from the National Renewable Energy Laboratory regarding clarifications of skeletal density and blank sample measurements.
- References collect for Cycle-Life section.
- Thermodynamics section input received and integrated from the Los Alamos National Laboratory.
- Received review of Thermodynamics section from Texas A&M University.
- Contributions to this project from world experts have been received including written materials, examples, presentation or editorial review of draft documents.
- Final Introduction section 100% complete.
- Final Kinetics section 100% complete.
- Final Capacity section 100% complete.
- Final Thermodynamic section in progress 95% complete.
- Final Cycle-Life Properties section in progress 95% complete.
- Draft Thermal Properties section started 15% complete.

Fiscal Year (FY) 2011 Objectives

- To prepare a reference document detailing best practices and limitations in measuring hydrogen storage properties of materials.
- The document will be reviewed by experts in the field.
- The final document will be made available to researchers at all levels in the DOE hydrogen storage program.

Technical Barriers

This project addresses the following technical barriers from the Storage section of the Fuel Cell Technologies Program Multi-Year Research, Development and Demonstration Plan:

- (A) System Weight and Volume
- (C) Efficiency
- (D) Durability/Operability

- Posted updated Preface, Introduction, Kinetics and Capacity sections to DOE website for world-wide access. Please download the current document from: http://www1.eere.energy.gov/hydrogenandfuelcells/storage/test_analysis.html

Introduction

The Hydrogen Storage goal is the development of hydrogen storage materials that meet or exceed the DOE's targets for the onboard hydrogen storage in a hydrogen-powered vehicle. The growth of research efforts in this field and new approaches to solving storage issues has brought the talents of a wide-range of researchers to bear in solving the grand challenge of hydrogen storage. There is a need to have common metrics and best practices for measuring the practical hydrogen storage properties of new materials that are being developed within the Hydrogen Storage sub-program as well as at an international level. H2 Technology Consulting is tasked with creating a clear and comprehensive resource that will provide detailed knowledge and recommendations for best practices in the measurements of these properties.

Approach

This project is a combined approach of documenting the experience the principal investigator and other experts in the field have with these measurement, incorporating examples from the literature, performing experimental measurements to demonstrate important issues, and finally, condensing key information into a concise reference guide. Each section covers such topics as the overall purpose of the measurements, some basic theory, experimental consideration, methods of measurement, and many details on both material properties and experimental factors that may strongly influence the final results and conclusions. Participation from other experts in the field is being sought out for input, relevant examples, and critical review at all levels.

The current document has been reviewed by many experts from around the world. We greatly appreciate the collaborative efforts of all of the reviewers: Professor Gavin Walker, University of Nottingham, United Kingdom; Dr. Thomas Gennett of the National Renewable Energy Laboratory in Golden, CO; Dr. Gary Sandrock and Dr. George Thomas, consultants to the U.S. Department of Energy; Dr. Michael Miller of Southwest Research Institute in San Antonio, TX; Dr. Anne Dailly and Dr. Frederick Pinkerton of General Motors R&D Center; Dr. Ole Martin Løvvik of the Institute for Energy Technology in Kjeller, Norway; Dr. Eric Poirier of NRC Canadian Neutron Beam Centre Chalk River Laboratories, Canada; Professor Channing Ahn of the California Institute of Technology in Pasadena, CA; Dr. Kevin Ott, Dr. Anthony Burrell, and

Dr. Troy Semelsberger of Los Alamos National Laboratory; Professor Richard Chahine, Université du Québec à Trois-Rivières, Canada; Professor Klaus Yvon, University of Geneva, Switzerland; Professor Sam Mao of the University of California Berkeley in Berkeley CA; and Dr. Nobuhiro Kuriyama and Dr. Tetsu Kiyobayashi of the National Institute of Advanced Industrial Science and Technology in Osaka, Japan. In addition, the work has been coordinated and has received important scientific input through our contract monitor Dr. Phil Parilla at the National Renewable Energy Laboratory.

Results

This year the Best Practices document had updates to the capacity measurements based on the need to elucidate measurement issues associated with low density, high surface area materials. In particular, the problems of small sample size and potential calibration errors due to helium adsorption. The need for blank sample measurements to validate accuracy was also addressed. The updated version including a preface, introduction, kinetics and capacity measurement sections is now posted on the DOE website.

This year's work focused in large part on finalizing the Thermodynamics and Cycle-Life measurements sections of the "Best Practices" document. For this work collaborations were established with the following contributing authors: Pierre Dantzer, Université Paris-Sud; Shengqian Ma and Hong-Cai Zhou, Texas A&M University; Kevin Ott, Tony Burrell and Troy Semelsberger, Los Alamos National Laboratory; Yevheniy Pivak and Bernard Dam, VU University Amsterdam and Delft University of Technology; and Dhanesh Chandra of the University of Nevada Reno. A rigorous review of the Thermodynamics section was completed by Professor Gavin Walker of the University of Nottingham. Through these collaborations the document has added perspectives of critical measurement issues from the three main materials research areas: on-board rechargeable hydrides, off-board regenerable hydrides, and hydrogen physisorption storage materials.

The objective of the thermodynamic section of the Best Practices document is to evaluate methodologies for determining equilibrium thermodynamics. In particular, there is a need to shed light on how to separate true equilibrium conditions from kinetic effects. Examples are included below of recent additions incorporated into the thermodynamic measurements section. Figure 1 shows a unique setup for high-throughput measurements of the enthalpy of formation of thin film combinatorial samples using Hydrogenography [1]. This method uses the classic conversion of pressure-composition-temperature isotherms of a reversible hydride to a van't Hoff plot for the determination of the enthalpy and entropy of hydride formation.

Hydrogenography consists of measuring the log of the optical transmission by means of a charge-coupled device

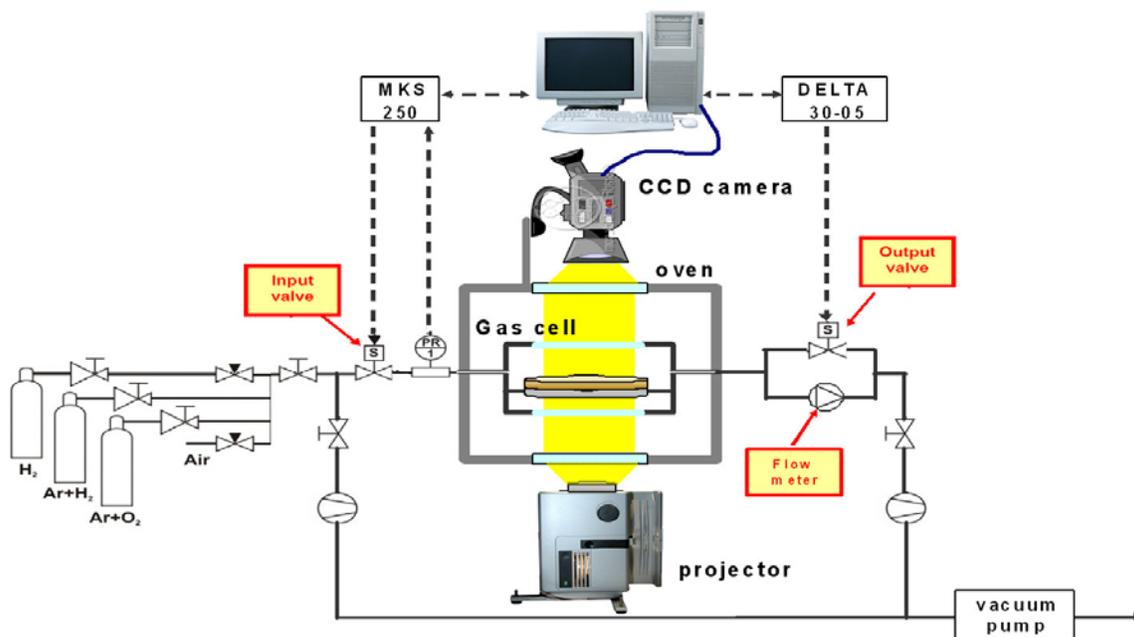

FIGURE 1. Schematic Representation of a Hydrogenography Setup [1]

camera through a thin film sample while increasing or decreasing the hydrogen pressure surrounding the sample. The optical transmission is proportional to the local hydrogen concentration of the material in the two-phase region. A rapid change in optical transmission indicates a hydride formation plateau. Thus, plateau pressures can be measured simultaneously at every point on two-dimensional combinatorial films having composition gradients. Repeating the measurement at several temperatures gives a van't Hoff plot for every point on the film and consequently every material composition. As an example of this, Figure 2 shows the phase diagram (left) and corresponding enthalpy map (right) of the Mg-Ni-Ti ternary system [2].

Cycle-life performance measurements are critical for evaluating the practical use of hydrogen storage materials in applications such as hydrogen-powered vehicles where hundreds to thousands of cycles will be required. An example of the impact on the hydrogen storage performance by making small changes in composition of the intermetallic compound LaNi_5 is shown below in Figure 3.

The Cycle-Life measurement section covers the advantages and disadvantages of different measurement methods. For example, measurements of the cycle-life performance of hydrogen storage materials can be performed using pressure-temperature cycling or, in some cases, far more quickly by performing a thermal aging process on test

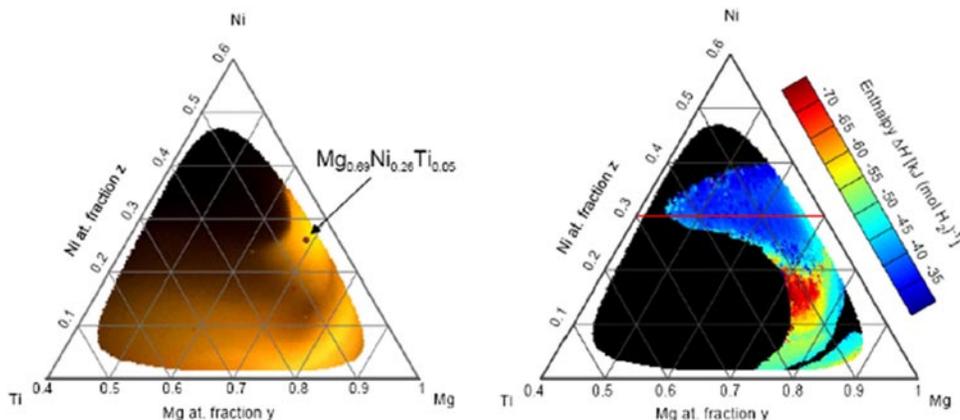

FIGURE 2. Ternary composition diagram (left) showing the final optical transmission state and the enthalpy map (right) of the Mg-Ni-Ti system, estimated using the optically determined hydrogenation plateaus. Black region on the right-hand picture represents chemical compositions that do not have a well defined plateau on the pressure-temperature isotherms [2].

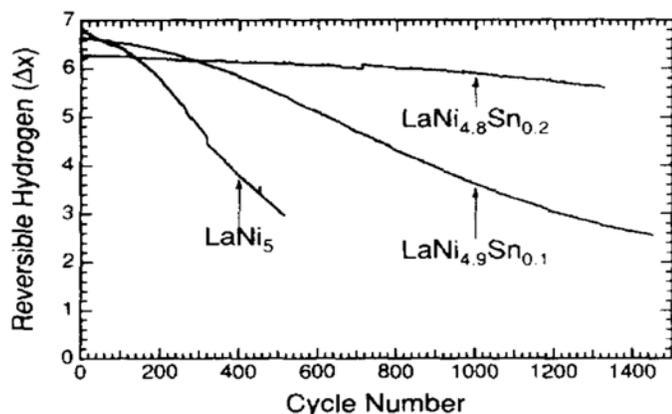

FIGURE 3. Hydrogen concentration changes Δx for $\text{LaNi}_{5-y}\text{Sn}_y\text{H}_x$ obtained from the maximum and minimum pressures for each cycle [3].

samples. In both cases, the measurements can be used to evaluate intrinsic performance degradation by using closed system designs which continuously cycle the same hydrogen gas. A comparison of results for LaNi_5 alloys using these two different methods and giving similar results is shown in Figure 4.

Conclusions and Future Directions

In FY 2011 we were able to establish important collaborations and technical assistance from experts in the field. We were able to update the Capacity section in a timely manner. We are currently working on completing the final versions of the Thermodynamic and Cycle-Life measurement sections.

Contract Number: DE-FG36-08GO18159

Subcontractor:

SCRA, Charleston, SC

Project Start Date: September 30, 2008

Project End Date: September 30, 2011

Objectives

- Over a three-year period, design and implement a pilot program for the initial H-Prize award under Section 654 of the Energy Independence and Security Act of 2007 (see the Introduction for a description of H-Prize).
 - If a qualified winner is identified, award \$1 million for a significant advancement in hydrogen storage materials for light-duty vehicle applications.
- Create a pilot award process.
- Organize and execute a comprehensive fundraising program to supplement and/or create other awards under Sec. 654.
- Combine the fundraising program with a systematic process that deploys collected funds through fair and open competitions.

Technical Barriers

This project addresses the following technical barriers from section 3.3: Hydrogen Storage of the Fuel Cell Technologies Program Multi-Year Research, Development and Demonstration Plan:

- (A) System Weight and Volume
- (C) Efficiency
- (D) Durability/Operability
- (E) Charging/Discharging Rates
- (G) Materials of Construction

- (J) Thermal Management
- (K) System Life-Cycle Assessments
- (Q) Reproducibility of Performance
- (R) Regeneration Process
- (S) By-Product/Spent Material Removal

Technical Targets

H-Prize consists of a series of contests that leverage private funds with core funding provided by the federal government to broaden the base of investment in development of hydrogen technology and advance that technology into the marketplace.

The first H-Prize in this series, for hydrogen storage, was designed to address the challenges that exist in advancing automotive hydrogen storage for fuel cell electric drive vehicles. Its goal was to produce a material that has the potential to be an on-board rechargeable hydrogen storage material. Specifically, the H-Prize required that the storage material have the following characteristics:

- Gravimetric capacity of >7.5 wt% hydrogen (releasable hydrogen):
 - Reversible hydrogen capacity between -40 to $+85^{\circ}\text{C}$, and between 1.5 to 150 bar hydrogen pressure.
- Volumetric capacity of >70 g/liter (releasable hydrogen):
 - Total volume of hydrogen ab/adsorbed by the solid plus the pressurized hydrogen contained within the pore spaces all divided by the total sample volume including the material's skeletal volume.
- Charging kinetics: greater than or equal to 4×10^{-4} (i.e. 0.0004) grams of hydrogen per gram of material per second:
 - Charging kinetics are to be measured with an inlet hydrogen gas temperature of between -40 to $+85$ degrees C and an inlet hydrogen pressure of not greater than 150 bar.
- Discharge kinetics: greater than or equal to 2×10^{-5} (i.e. 0.00002) grams of hydrogen per gram of material per second:
 - Discharge kinetics are to be measured at a sample temperature between -40 to $+85^{\circ}\text{C}$ and with an outlet hydrogen pressure of greater than or equal to 1.5 bar.
- Cycle life of >100 cycles.
- At completion of 100 charge/discharge cycles from less than 5% to greater than 95% of reversible capacity, the sample's reversible capacity must still be greater than or equal to 95% of the gravimetric capacity target (i.e. ≥ 0.95 times 7.5 wt% or ≥ 7.1 wt%).

Figures 1 and 2 show the relationship between the state of the art for hydrogen storage in 2008 and 2011 compared to the gravimetric and volumetric targets for the hydrogen storage material sought by the first H-Prize.

Accomplishments

Task 1: Contest Rules

- Specific goals and technical targets were established in partnership with DOE staff.
- Feedback was sought from industry and the hydrogen community on technical evaluation criteria for initial H-Prize contest; draft criteria were presented to the Hydrogen and Fuel Cell Technical Advisory Committee (HTAC) in November 2008 and Hydrogen Interagency Working Group in December 2008.
- Set of criteria and basic contest parameters for inclusion in a draft Federal Register Notice was submitted to DOE for review and action in February and March 2009.

Task 2: Announce and Promote Contest

- Preliminary presentations made in November 2008 (to HTAC) and December 2008 (to the Hydrogen Interagency Working Group).
- First announcement was made at National Hydrogen Association Annual Conference in March-April 2009.

- Poster presentation during DOE Annual Merit Review in May 2009.
- Federal Register Notice released on August 26, 2009, announcing the beginning of the outreach campaign.
- HEF press released about contest on September 30, 2009.
- H-Prize website operational at <http://hydrogenprize.org>.
- Presentation about H-Prize to conference: *Hydrogen Production and Storage* in October 2009.
- Presentation at Resources for the Future in Washington: *The Role of Prizes in Innovation and Entrepreneurship* in December 2009.
- Scores of individual calls and e-mails were sent to people we could identify who were working in or interested in this niche area of hydrogen storage.
- E-mail campaigns were sent out to HEF's 30,000+ person hydrogen and fuel cell mailing list to attract other interest.
- Of 20 registrants, 15 submitted all the materials necessary to participate in the contest.

Task 3: Judging

- In consultation with DOE staff, the panel of judges was developed and their willingness to participate was confirmed.

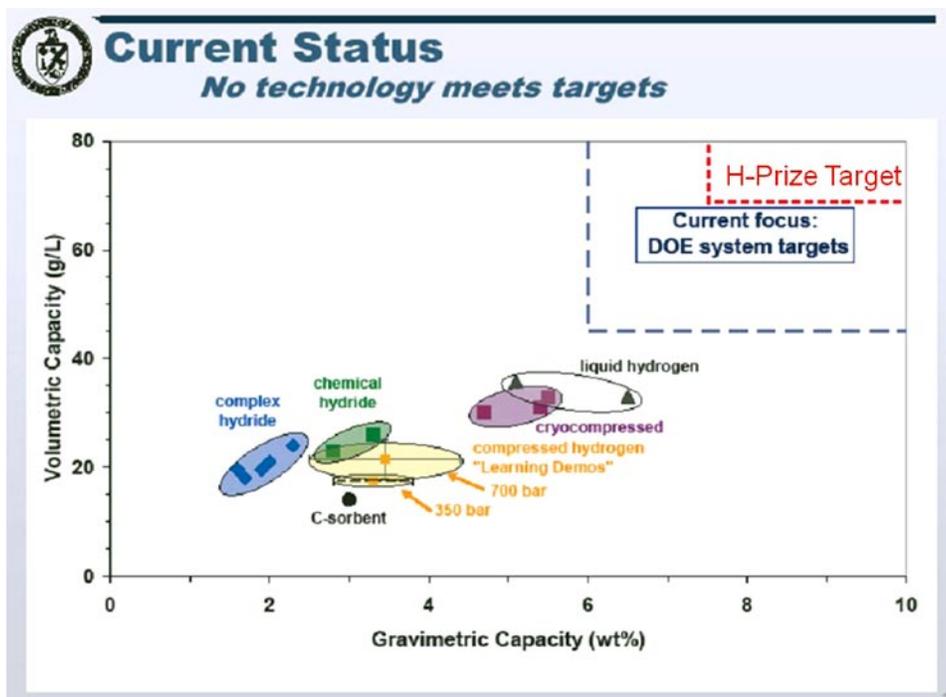

FIGURE 1. H-Prize Targets Relative to the State of Hydrogen Storage Technology as Reported by DOE in 2008 (modified from "Hydrogen Storage," Sunita Satyapal, 2008 Annual Merit Review Proceedings to include H-Prize targets)

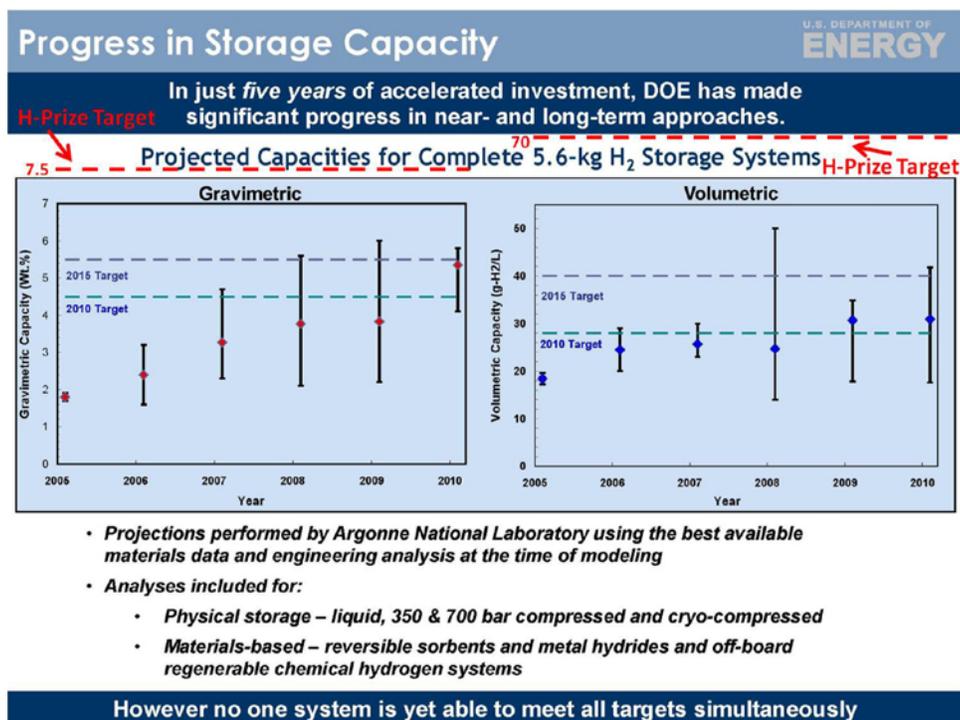

FIGURE 2. H-Prize Targets Relative to the State of Hydrogen Storage Technology as Reported by DOE in 2011 (modified from “Overview of Hydrogen Storage,” Ned Stetson, 2011 Annual Merit Review Proceedings to include H-Prize targets)

- In third quarter of 2010, HEF staff and DOE completed Conflict of Interest and Non-Disclosure Agreement forms for panel of H-Prize judges.
- HEF Board of Directors approved slate of recommended judges in third quarter of 2010.
- With the November 15, 2010 deadline for receipt of materials approaching, HEF staff prepared and sent a detailed message to all the eligible H-Prize participants to remind participants of the key upcoming contest deadlines, discuss contest procedures for testing and verification, and encourage the participants to secure their independent testing with adequate time for meeting the November 15th deadline should their storage material qualify.
- Two eligible participant teams, Microbes Unlimited and Zaromb Research Corporation, submitted their testing results. Both submissions were found not to meet the minimum requirements set by the H-Prize and therefore were not sent off to our independent laboratory.
- Zaromb Research Corporation did write a letter disputing the judges’ findings. Judge, Bob Bowman, and DOE Staff, Ned Stetson, collaborated on a response to address the issue. They refuted Zaromb Research Corporation’s argument.
- No team qualified to advance to the next phase of the Competition.

Task 4: Management

- Kick-off meeting held on October 17, 2008.
- Revised budgets and award contingencies remedied.
- HEF staff met with DOE on March 24, 2010 to discuss next steps and upcoming work items for the H-Prize, such as the judging process, details for how to conduct the required sample testing, and a status update on HEF’s administration of the contest. HEF and DOE staff discussed selections for the H-Prize’s judging panel.
- Draft conflict of interest and nondisclosure agreements necessary for judging panel were completed.
- Receipt of test results and materials for subsequent independent verification of results deadline was November 15, 2010.

Task 5: Fundraising

- Marketing lists and fliers created in mid-2009 and awaited Federal Register notice authorization.
- Subcontractor SCRA developed and executed the majority of the fundraising plan.
- Outreach completed by physical mail and phone to 226 different foundations identified as having interest in supporting energy-related programs.
 - Received over 130 rejections for funding including 100% of our “top prospects.”

- Successful application to the 2010 Combined Federal Campaign (CFC).
- Promoted the H-Prize and Hydrogen Education Foundation to CFC offices around the country to encourage donors.
- Launched an online ad campaign on Govexec.com that targeted visitors interested in activities at the Department of Energy, Green Government, as well as a run of site for visitors in the D.C. area.
- Received donations from 30 different CFC administrators around the U.S. totaling about \$2,300 at the time of writing.
- Utilized a mobile fundraising service to reach a broader audience of givers and allow givers to donate by text message.
- Sent out individual letters to key contacts/philanthropists, asking for individual donations.

Introduction

The H-Prize was created by an act of Congress as part of the Energy Independence and Security Act of 2007, Section 654, to accelerate the development of hydrogen and fuel cell technologies by offering prizes to motivate and reward outstanding scientific and engineering achievements. H-Prize consists of a series of contests that leverage private funds with core funding provided by the federal government to broaden the base of investment in development of hydrogen and fuel cell technologies and advance that technology into the marketplace.

Approach

HEF staff worked in concert with DOE to develop a contest that supported DOE's program and the legislation enacted by Congress. The first competition was designed to address challenges in hydrogen storage. While developing the Contest, we solicited feedback from industry stakeholders (both individual experts and groups like DOE's HTAC) to create the guidelines and parameters for assessing entries.

In parallel, a vigorous fundraising campaign was launched by HEF and its former subcontractor SCRA to seek non-government financial support for future contests named in the legislation. Over 220 potential sponsors were identified and contacted for possible funding of the contest. In addition, HEF staff applied for and succeeded in participation with the CFC in 2010. HEF has also been accepted into the 2011 CFC.

In addition to the fundraising efforts for future prizes, a marketing campaign was created to promote the first H-Prize competition for on-board hydrogen storage once the theme and guidelines were finalized. After input from various experts and stakeholders, the guidelines were

approved by the HEF board of directors and the U.S. Department of Energy and published in the Federal Register in August 2009.

Announcements were made at several industry events, such as the National Hydrogen Association's Annual Conference in Columbia, South Carolina and DOE's Annual Merit Review, through press releases, and individual contact to hydrogen storage experts and groups. Staff developed a contest website, <http://www.hydrogenprize.org> for communicating the contest to the public and to serve as a tool for administering the competition.

Results

Administration of the H-Prize for Hydrogen Storage:

Applying to compete in the H-Prize for Hydrogen Storage included these basic four steps:

- Register online.
- Submit your application.
- Submit independent testing results showing that your material meets the established criteria.
- Submit a sample of the material for testing by the H-Prize's official laboratory.

For this first completion, a total of 20 organizations registered to participate. Given the niche focus on a specific area of hydrogen storage plus the fact that many of the experts in the hydrogen storage community are funded in part through DOE projects (and therefore were not eligible to compete), this left a very small number of potential applicants. We believe that these 20 registrants represented a majority of the people who could have qualified to compete.

Of the 20 registrants, 15 entities submitted full applications to be considered for the H-Prize and when the deadline passed to submit independent testing results, only two contestants remained. (The 13 organizations who withdrew cited costly independent laboratory work and a lack of resources to complete the required testing.)

The two remaining contestants, Microbes Unlimited and Zaromb Research Corporation, submitted their test results to the HEF and judging panel for review and to determine whether the contestants were qualified for step 4: to submit their hydrogen storage material for testing. The judges determined that the test results from Microbes Unlimited and Zaromb Research Corporation were insufficient for the prize to be awarded based on the parameters identified in the contest. Since both submissions were found not to meet the minimum requirements set by the H-Prize, no materials were requested or tested by the H-Prize laboratory.

Zaromb Research Corporation did write a letter disputing the judges' findings. Chief Judge, Bob Bowman, and DOE's Hydrogen Storage Team Leader for Metal

Hydrides, Ned Stetson, collaborated on a response to address the issue refuting Zaromb Research Corporation's argument. No team advanced to the next phase of the competition and the \$1 million prize was not awarded. The contestants were notified, but no public announcement was made.

Looking ahead, significant opportunities exist to administer future prizes differently, and we have options to use the unawarded \$1 million prize money in other areas to broaden the base of investment in development of hydrogen and fuel cell technologies.

Fund-Raising for Future H-Prizes:

During the fund-raising period for the H-Prize, over 220 foundations, tens of thousands of individuals and more than 100 companies were contacted to donate funds to support current or future H-Prizes described by the Sec. 654 legislation. Unfortunately, the results of this significant fund-raising effort did not bear the large sum of donations sought: \$1-5 million.

From the more than 220 foundations, we received over 130 rejections for funding including 100% of our "top prospects." Since this was one of the primary tactics envisioned for fund raising, once we received rejections from most of our top prospects, we changed our approach and reallocated funding into other areas to try new methods to attract new funding. That shift mostly included utilizing the CFC and raising awareness of HEF's participation in it.

At the time of writing, approximately \$2,300 had been collected, entirely from individual donations made through 30 different administrators for the 2010 CFC. Since all but one of the donations were anonymous, we do not know how many donors contributed, but the distribution of the CFC administrators that sent in checks to the HEF seem to indicate that our marketing had good nationwide reach and an unexpected international reach as well. The largest donations were received from the following CFC administrators:

- CFC-Overseas
- National Capital Area CFC
- CFC Portland Oregon
- Southeast Connecticut CFC
- South Hampton Roads (VA) CFC
- Texas Gulf Coast CFC
- Heart of Alabama CFC

We believe the small number of dollars collected can be mostly attributed to a few key things:

- Depressed economy (foundations, corporations and individuals all cited a lack of available resources).
- The subject of the current H-Prize in a very niche area of a technical field did not have the mass/popular appeal to attract funding from entities that would be considered "outside the choir" of the hydrogen and fuel cell industry.

- The technique for reaching out to foundations has changed significantly from the time we competed to administer the H-Prize to the time we started reaching out foundations. More specifically:
 - In the past, one could be successful with a well composed letter, printed materials about the proposed project, follow-up phone calls, etc. (in other words, fund raising remotely).
 - Today, after consulting with foundation fund-raising experts to try to learn if we could change our approach to increase our success with foundations, we learned that hardly anyone raises funds with foundations without first developing an in-person relationship with the foundation's staff. This equates to travel and significant time which the budget of this project was not designed to support.
 - As a result, we decreased our work with our fund-raising subcontractor and added resources to other creative fund-raising methods, including the CFC.

Conclusions and Future Directions

The initial H-Prize contest was not awarded as the two organizations competing for the prize did not meet the criteria for awarding the prize as was determined by the judging panel. In assessing the theme and parameters post-contest, it has become clear that the initial contest was quite limited in scope and the bar set extremely high (see Figures 1 and 2), thus reducing the numbers of prospective contestants. However, if the goal was to reach most of the American organizations who were not receiving DOE funding in hydrogen storage to encourage greater investment among this group, we believe that goal was reached. The number of people who meet these qualifications just happens to be very small.

The staff at the HEF will meet with DOE's H-Prize Manager, Dr. Ned Stetson to discuss lessons learned and new ideas for a new H-Prize since some administration funds remain as well as the \$1 million prize money. Prior to this meeting, the HEF will reach out to industry stakeholders to seek input on the challenges they are experiencing today and how the H-Prize may help address those challenges within the context of its objectives as defined above. Initial discussions with colleagues in the hydrogen community have revealed that there is a desire to strengthen relations between hydrogen and fuel cells with the broader renewable energy community including solar, biomass, and wind.

With a fully functional website that is active, marketing capabilities established, and lessons learned from the initial contest, DOE has a significant opportunity to build on these resources to create an even more successful prize in several different categories named in the H-Prize legislation. HEF staff looks forward to discussion what options exist in working with DOE on a second H-Prize in the near future.

- Fibras Sinteticas de Portugal (FISIPE), SA, Lavradio, Portugal

Project Start Date: November 2006

Project End Date: Project continuation and direction determined annually by DOE

Fiscal Year (FY) 2011 Objectives

- Reduce the manufacturing cost of high-strength carbon fibers by using melt-spun polyacrylonitrile (PAN) precursor technology which has the potential to reduce the production cost by >30%.
- Develop advanced conversion techniques that will significantly reduce the production cost of high-strength carbon fibers suitable for use in compressed hydrogen storage vessels by an additional 20%.

Technical Barriers

High-strength carbon fibers account for approximately 65% of the cost of the high-pressure storage tanks. This project addresses the following technical barriers from the Storage section of the Fuel Cell Technologies Program Multi-Year Research, Development and Demonstration Plan:

- (A) System Weight and Volume
- (B) System Cost
- (D) Durability/Operability
- (G) Materials of Construction

High-strength carbon fiber enables the manufacture of durable, lightweight, compressed hydrogen storage vessels for use in high-pressure storage. Unfortunately, current

high-strength carbon fiber products are far too expensive to meet DOE goals for storage system costs.

Technical Targets

Working targets are approximate equivalence with Toray T-700 at substantially reduced production costs:

- 700 ksi ultimate tensile strength.
- 33 Msi tensile modulus.
- Production cost reduction of at least 25% versus baseline.

FY 2011 Accomplishments

- Acrylonitrile copolymers were successfully prepared in controlled molecular weight by classical free radical copolymerization. It has been extended to copolymers with methyl acrylate. The materials have been characterized by melt rheology, fiber spinning, mechanical testing, microscopy and size exclusion chromatography (SEC).
- Demonstrated it is possible to use water as the only plasticizer (instead of water plus organic solvents like acetonitrile) to generate melt-spun PAN fibers as carbon fiber precursors.
- Demonstrated it is possible to melt-spin PAN precursor fibers with the desired denier (10 to 20 microns in diameter) with a one-step spinning/drawing process.

Introduction

The exceptional strength-to-weight ratio of carbon fiber composite tanks makes them prime candidates for use with materials-based, cryogenic, or high-pressure gas for both vehicular and stationary storage applications. Cost is the primary issue with composite tank technology. A critical challenge lies in the cost of the fiber and the manufacture of composite tanks. Current projections of the manufactured cost per unit for high production volumes are about a factor of nine above storage system targets, and it is estimated that about 40-70% of the unit cost is due to the base cost of the carbon fiber (approximately 40% of the fiber cost is due to the precursor and the remainder due to thermal processing). Research and development (R&D) is needed as composite storage technology is most likely to be employed in the near term for transportation applications and will be needed for most materials-based approaches for hydrogen storage.

Currently, composite tanks require high-strength fiber made from carbon-fiber grade PAN precursor. Manufacturing R&D is needed to develop lower cost, high

quality PAN or alternate precursors and reduced energy or faster conversion processes for carbon fiber, such as microwave and/or plasma processing. Developing and implementing advanced fiber processing methods has the potential to reduce cost by 50% as well as provide the technology basis to expand U.S. competitiveness in high-strength fiber manufacturing [1].

This project will leverage previous and ongoing work of the FreedomCAR's program to develop a low-cost, high-strength carbon fiber. At this time, the cost and property targets needed for compressed hydrogen storage are not well understood. Analysis is underway at DOE to determine appropriate targets. Until targets are definitively established, this project will seek to develop carbon fibers with properties equivalent to Toray's T700/24k fiber (24k tow, 700 ksi ultimate tensile strength, 33 Msi tensile modulus), and reduce production costs by at least 25%.

Approach

This project is structured into tasks focused on precursor development and conversion process improvements. Development and demonstration of melt-spinnable PAN is the project's primary precursor option. This requires concurrent activities in both development of melt-stable PAN copolymer and blends as well as the processes necessary to successfully spin the formulations into filamentary tows. Backup options include textile PAN, polyolefins, and incorporation of nanomaterials. Demonstrating and down-selecting a precursor capable of meeting performance targets utilizing conventional conversion processing defines the pathway for the balance-of-project activities. In conversion, critical processability parameters include: (i) highly controlled stretching, especially during pre-treatment and stabilization; (ii) residence time in various conversion modules; (iii) optimal graphitization for maximum strength; (iv) uniform treatment of fibers throughout the tow; and (v) characterization of filaments at various stages of conversion operation. Related ORNL work in advanced processing technologies address these issues, with a focus on increasing line speed in a reduced footprint, with reduced energy consumption. Means to adapt these emerging processes will be developed and evaluated for applicability to meeting requirements of this program area. As the alternative approaches are demonstrated, the energy efficiency and overall economics of the complete system will be evaluated and forecast for production scale up.

Results

Melt processing of PAN is a difficult issue, although Virginia Tech and others have made modest progress over the last decade [2-6]. One of the principal problems is that PAN degrades even without main chain scission or weight loss, and this essentially precludes melt processing. Reactions of the side groups have been discussed in many

reports [7-10]. These degradative reactions can take place both in an intra-molecular manner, but also via inter-molecular branching and gelation, which quickly alters the capacity for these materials to be melt fabricated. At 200-220°C, the material can quickly increase in viscosity, thus rendering an intractable material in a very short time. Ideally, one would like to maintain constant viscosity for a required period, and practical considerations suggest that this should be at least 30 minutes or longer.

Random copolymers have been made either by aqueous suspension processes or emulsion systems using polyvinylpyrrolidone for the suspension aid and common organic initiators such as azobisisobutyl nitrile (AIBN) and peroxides. Monomers such as acrylonitrile methyl acrylate, hema, caprolactone and 2-acrylamido-2-methyl-1-propanesulfonic acid were purchased from laboratory supply houses. The suspension reactions were conducted mostly in a Parr reactor, which prevents loss of monomer through typical three-neck type apparatus systems. Conversions can be very high; molecular weights were controlled primarily with temperature, initiator concentration, and especially the use and concentration of dodecyl mercaptan as a chain transfer agent. Characterization of the co- and terpolymers utilized spectroscopic methods various rheological measurements.

In some cases, preliminary experiments were done in dimethyl sulfoxide, again using AIBN to produce effective random copolymers. Macromonomer grafts were prepared by utilizing hydroxy ethyl methacrylate to initiate caprolactone in the presence of catalytic quantities of stannous octanoate. The resulting methacrylic functionality macromonomer of about 1,000 to 2,000 molecular weight was successfully introduced into the terpolymerization scheme with acrylonitrile and methylacrylate. The rheological behavior was investigated for the copolymers and concurrently for the terpolymers. As shown in Figure 1, there was a noticeable effect of composition on the apparent melt viscosities; 90% or less could produce in many cases a melt processible material, which evidenced little if any degradation over a 30-minute processing period.

A laboratory-pressurized spinning system was developed, which enabled viscosity shear rate behaviors to be generated as a function of temperature and water content. A descriptive plot of viscosity vs. shear rate is provided in Figure 2. The resulting materials could be processed into fibrous materials, which are undergoing continued evaluation. All of the materials described were well characterized by SEC, which has been invaluable in establishing which compositions and molecular weights are indeed melt processible. The work is ongoing and an updated presentation will be given at the meeting.

In FY 2010, the project achieved success in generating a ten-filament mini-tow with AN/VA copolymer. The scanning electron microscope micrographs showed that the void size of the fibers is similar to that of as-spun fibers produced by BASF. The tensile strength of melt spun fibers was about 50 to 70% of industrial precursor fibers which were solution

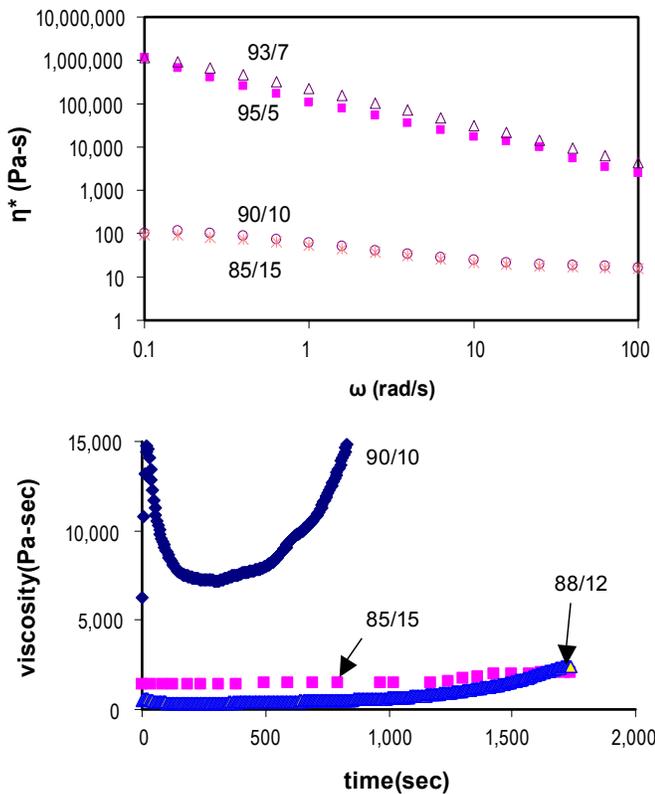

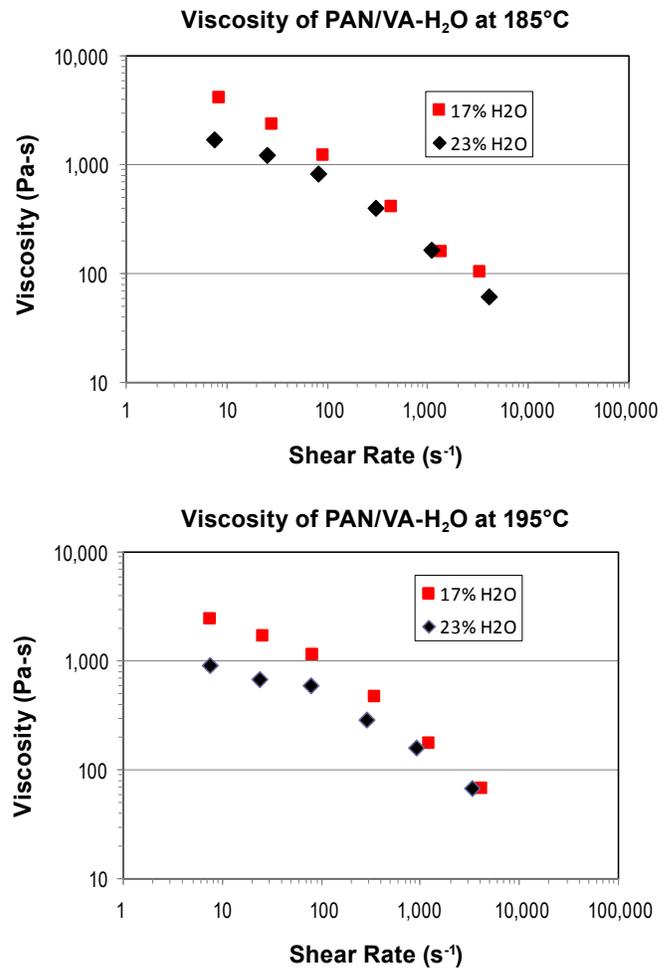

FIGURE 1. Correlation between Melt Viscosity and Copolymer Composition

spun and about four times smaller in diameter. It is expected that with a new spinneret that fibers in the range of 10 μm will be produced with significantly improved strength.

In Table 1, the tensile mechanical properties of VT melt-spun PAN fibers are presented. The properties of industrial precursor fibers are also included in the table/figures for comparison. The strength of VT melt-spun fibers is lower than all industrial precursor fibers, whereas the elongation of VT fibers is similar to that of the industrial fibers, especially Courtaulds and Hexcel fibers. Note that VT fibers are four times larger than all industrial fibers. Because smaller fibers usually have higher strength, the higher strength of melt-spun fibers would be expected when the fiber diameter is reduced to 10 μm or so with the new spinneret.

The viscosity of melt decreases as water content increases.

FIGURE 2. Viscosity of AN Copolymer-H₂O Melt

In FY 2011 efforts were made to design and fabricate a new spinneret (with diameter of 55 microns) and use it to generate a multi-filament (≥10 filaments) precursor tow with AN/VA copolymer (containing 93% AN), targeted at filaments with diameter of 10 to 20 μm and porosity of no more than 1 vol%. Success was achieved in generating melt-spun PAN precursor fibers with diameter of 10 to 20 microns. Effort is now focused on issues associated with

TABLE 1. Mechanical Properties of VT Melt-Spun and Commercial PAN Precursor Fibers*

Name/ Manufacturer	Polymer Composition	Spinning Process	Fiber Diameter (μm)	Peak Stress (KSI)	Strain at Break (%)
VT-1	AN/VA	Melt/H ₂ O	67.1 (3.1)	37.6 (3.7)	11.89 (1.16)

* All data were provided by ORNL. Data in parenthesis represent the standard deviation.

generating filaments or a mini-tow with uniform diameter and length greater than 10 ft and preferably up to 100 feet.

A new spinneret with 18 capillaries was designed and built for evaluation. The capillary has a diameter of 55 microns and L/D of 5. It turned out that the spinneret was poorly machined with unacceptable deviation in the capillary diameters. The design was modified and a better qualified company was found to machine the spinneret. As can be seen from Figure 3, the latest spinneret has 19 capillaries with diameter of 55 microns and aspect ratio (L/D) of 2. The spinneret was received on April 19 and appears to be well machined.

PAN fibers produced with the new spinneret are shown in Figure 4. The fibers have a diameter of 10 to 20 microns. The evaluation of the fibers including mechanical property and morphology of the fibers is now underway.

Conclusions and Future Directions

Acrylonitrile copolymers were successfully prepared in controlled molecular weight by classical free radical copolymerization. It is has been extended to copolymers with methyl acrylate. The materials have been characterized by melt rheology, fiber spinning, mechanical testing, microscopy and SEC. Stabilization appears to require 1 or 2 wt% of a novel stabilizer. The stabilization mechanism is unknown, but one speculates a sort of pH control which retards the intra and inter molecular cyclization process. Small amounts of water are observed to be released and a

significant increase in Tm has been reported. This suggests that the stabilizer may also serve as a nucleating agent, which could be very important. The utilization of water as a plasticizer has been one of the critical observations

FIGURE 4. Melt-spun PAN/VA fibers using 19-filament die (0.0022" in diameter). The diameter of fibers is about 10 to 20 microns.

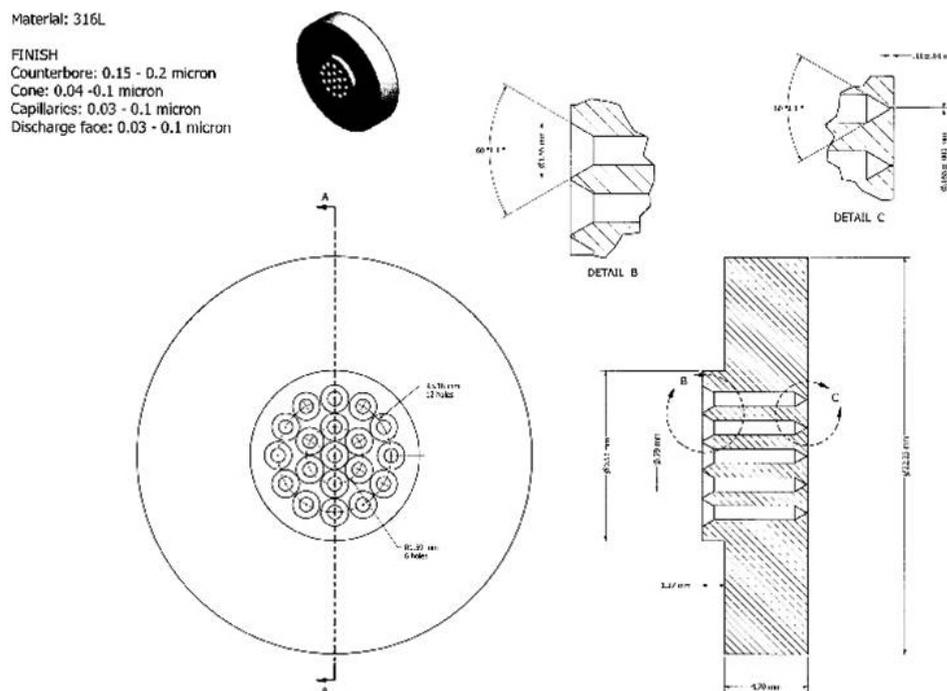

FIGURE 3. Drawing of new spinneret for Instron rheometer fiber spinning system. The spinneret has 19 capillary holes with diameter of 55 microns.

developed thus far that generally permits melt spinning via decreasing the dipole interactions. Controlled (living) radical copolymerization is currently also being explored. This is expected to afford narrower molecular weight distributions and possibly lower branching and chain end unsaturation.

The fiber spinning research so far reveals that:

- It is possible to use water as the only plasticizer (instead of water plus organic solvents like acetonitrile) to generate melt-spun PAN fibers as carbon fiber precursors.
- It is possible to melt-spin PAN precursor fibers with the desired denier (10 to 20 microns in diameter) with a one-step spinning/drawing process.
- In order to generate PAN precursor fibers with desired size and quality, one must have a quality spinneret with small capillary size. However, it was found very difficult to remove the residual PAN polymer from capillaries with diameter of 55 microns or so. Effort is ongoing to overcome this difficulty.
- It was found to be very difficult to remove the residual PAN polymer from the capillaries with diameter of 55 microns. Using solvent to dissolve the polymers at elevated temperature, or using high temperature (~400°C) plus oxygen to burn-off the polymers and then clean the capillaries have been attempted. Unfortunately, none of the methods could clean the capillary completely even after days/weeks of treatment. We are still working on this issue so that we can keep running the fiber spinning experiment with the small capillary diameter spinneret.

Near-term objectives are to:

- Generate a multi-filament (≥ 10 filaments) precursor tow with AN/VA copolymer (from ORNL with 93% AN), targeted at filaments with diameter of 10 to 20 μm , porosity of no more than 1 vol%, and length of greater than 10 feet.
- Generate a multi-filament (≥ 10 filaments) precursor tow with AN/MA copolymer (from ORNL, with 95% AN) with desired size and properties.
- Test mechanical property and morphology of PAN/VA and PAN/MA fibers and compare them with that of industrial precursor fibers.
- Consider the design of an extrusion process using an extruder which will allow the generation of a larger quantity of fibers.

ORNL will characterize fiber and conduct conversion trials on precursor filaments generated using its precursor evaluation system. The filaments at various steps of the conversion process will be fully characterized and the data

used to commence optimization of precursor chemistry and the filament generation process. We expect to achieve carbon fiber tensile properties of 15 Msi elastic modulus and 150 ksi tensile strength with 1st generation filaments. We are targeting 18 Msi modulus and 200 ksi strength in 2nd generation filaments.

Start Date: June 2008
Projected End Date: Project continuation and
direction determined annually by DOE

FY 2011 Accomplishments

- Permeation measurements on specimen of Lincoln Composites Type IV high-density polyethylene (HDPE) tank liner show progressive changes in the slope and pre-exponential scaling factor of the permeation curves that occur as the specimen undergoes simulated lifecycle temperature variations.
- Characterization of liner specimen using neutron scattering and electron microscopy (small angle neutron scattering [SANS], ultra small angle neutron scattering [USANS], scanning electron microscopy/back scattered electron mode [SEM/BSE]) show significant structural changes were induced by temperature cycling or hydrogen exposure or both.
- Using permeation coefficient data, the Lincoln Composites HDPE liner in a 350-bar tank can be expected to maintain an H₂ leak rate that meets applicable leakage standards throughout its lifecycle history.

Fiscal Year (FY) 2011 Objectives

Perform durability qualification measurements on specimens of Type IV storage tank liners (polymers) at the nominal working pressure using thermal cycling commensurate with the design lifetime, followed by permeation measurements to determine if the steady-state leakage rate in the tank could potentially exceed the specification for hydrogen fuel cell passenger vehicles.

Technical Barriers

This project addresses the following technical barriers from the Hydrogen Storage section (3.2.4) of the Fuel Cell Technologies Program Multi-Year Research, Development and Demonstration Plan:

(D) Durability/Operability

Technical Targets

This project addresses the following technical targets for on-board hydrogen storage systems research and development [1]:

- Cycle life variation, expressed as percent of mean (min) at percent confidence:
 - FY 2010: 90/90; FY 2015: 99/90
- Environmental Health and Safety:
 - Permeation and leakage: meets or exceeds applicable standards.
 - Loss of usable H₂ (g/h/kg H₂ stored): FY 2010: 0.1; FY 2015: 0.05.

Introduction

Modern high-pressure hydrogen storage tanks use a polymeric liner as a permeation barrier to hydrogen, typically HDPE. Storage tank liners can, however, be stressed by cyclical excursions between temperature extremes, and the cumulative effects of repeated stress could harm the tank's durability. Ultra-high environmental temperatures can promote large hydrogen permeation rates and hydrogen saturation in the liner material. Ultra-low environmental temperatures can severely stress liner materials and possibly induce microcracking. In addition, increasing the pressure of gas in such a tank during filling necessarily raises the temperature of the gas and therefore the enclosing tank. Over the course of many fill cycles during the lifetime of the tank this might affect the permeability characteristics of the liner. Failure modes for the liner's performance based on the interaction of high pressure and extreme temperature cycling might be possible. Hydrogen leakage through a liner microcracked by extreme temperature cycling could accelerate under sustained high temperature and pressure, or hydrogen saturation of the reinforcement layers external to the liner could put backpressure on the liner as the tank pressure decreases during vehicle operation, thereby causing the liner to separate from the reinforcement layers. Minimum temperatures during winter months in northern states may reach -40°C, and maximum temperatures after filling during summer months may reach 125°C. Thus, the purpose of this project is to cycle typical tank liner materials between

these temperature extremes to determine whether such a degradation in properties occurs, and if so, its extent.

Approach

Hydrogen permeation verification measurements for storage tank liner materials are being carried out using ORNL's internally heated high-pressure permeation test vessel (IHPV). The IHPV was previously used in the hydrogen delivery program to measure real-time hydrogen permeation in low-carbon steels and polymer materials at constant temperatures. Materials properties such as the temperature- and pressure-dependent hydrogen solubilities, diffusion coefficients and permeation coefficients are extracted from measurements of real-time hydrogen flux through steels and polymers. In the previous project year we modified the IHPV to enable rapid temperature cycling in polymer specimens.

We are using the relevant portion of the test protocol specified in Society of Automotive Engineers standard J2579 [2] to guide our performance of durability test cycling measurements of high-pressure polymeric tank liners. The J2579 test protocol for compressed hydrogen storage systems prescribes long-term thermal cycling at high pressures of hydrogen. The requirement is to subject tank liner specimens to 5,500 thermal cycles over the temperature range -40 to 85°C at hydrogen pressurizations of 43 MPa (6,250 psia) and then 86 MPa (12,500 psia). Testing at 43 and 86 MPa, with cycling between -40 and 85°C, requires an automated temperature control strategy. To replicate the rapid temperature rise in the tank liner during fill cycles (approximately 100°C rise in 3 minutes) we decoupled the cooling and heating control systems in the IHPV. A low-temperature chiller with low-temperature refrigerant circulating to and from a sealed reservoir cools the IHPV's exterior containment vessel to approximately -40°C. A resistive heater situated in the permeation cell is used to ramp the specimen temperature from -30°C to 85°C. A heater controller controls the thermal cycling of the polymer specimen in the cell by applying and removing power to the heater. Process control software that was developed for the temperature-controlled permeation measurements in steels and polymers was modified to provide automated, unattended operation and Internet access so the tests can be remotely monitored and controlled. A complete heating and cooling cycle requires 33.3 minutes, and approximately 127 days are required to perform 5,500 temperature cycles.

The verification measurements occur at regular intervals during the 5,500 temperature cycles. The hydrogen flux is measured at multiple temperatures in the range -30 to 85°C at each interval. The first measurements occur after the completion of 250, 500, 750, 1,000, 1,250 and 1,500 cycles. The remaining measurements occur at 500 cycle intervals until 5,500 temperature cycles have been reached.

Results

We completed permeation measurements on a Lincoln Composites Type IV tank liner specimen (HDPE). The permeation coefficients P have the temperature dependence of an activated process, $P = P_0 \exp(-E_A/kT)$, where the pre-exponential scaling factor P_0 and the activation energy E_A are presumed to be independent of temperature. We performed permeation measurements before cycling and after 250, 500, 750, 1,000, 1,250, 1,500, 2,000, 2,500, 3,000, 3,500 and 4,000 cycles. Semi-log plots of P versus $1/T$ are shown in Figure 1. Lines have been drawn through measurements at 0, 1,000, 2,000, 3,000 and 4,000 cycles to illustrate the systematic changes in E_A and P_0 . The decreasing slope and shift in scaling indicates that some physical change occurred in the polymer during cycling, but we did not observe a statistically significant departure from the Arrhenius relationship, which would indicate that microcracking or changes in glass transition temperature had occurred in the polymer. Figures 2a and 2b illustrate the changes in E_A and P_0 , respectively. E_A and P_0 each decreased as the specimen was subjected to repeated temperature cycles. The -2.21 J/mole slope for E_A versus number of cycles was approximately five standard deviations from a slope of zero, and the 4.6×10^{-8} mol H₂/cm·s·bar slope for P_0 versus number of cycles was approximately 4 standard deviations from a slope of zero.

Following completion of the temperature cycling we used neutron scattering analysis (SANS and USANS) to look for structural changes on the order 1 nm to 30 μm in

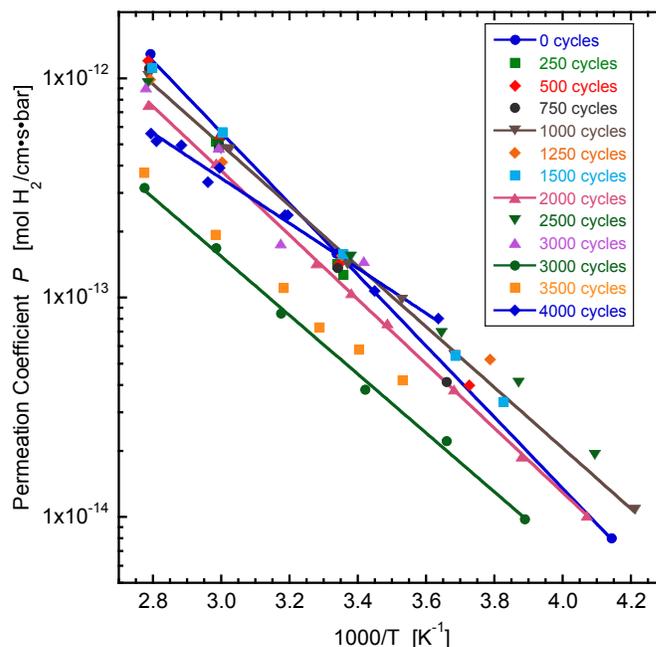

FIGURE 1. Permeation Coefficients P for Hydrogen in Polymer Specimen, Measured at 430 bar

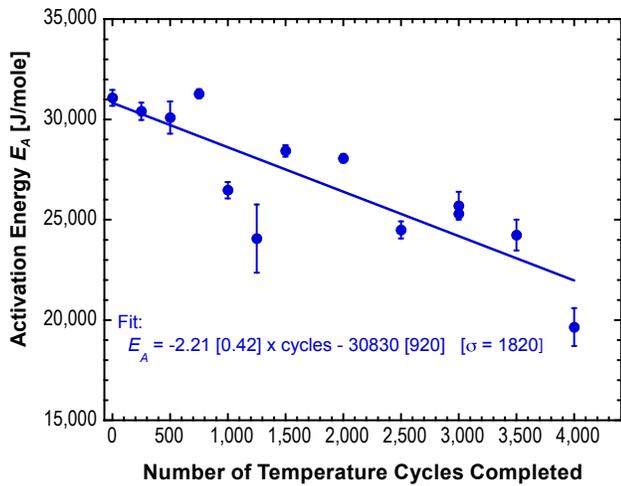

FIGURE 2a. The activation energy E_A of the HDPE specimen decreased through 4,000 temperature cycles, indicating that the polymer experienced small changes in its microstructure.

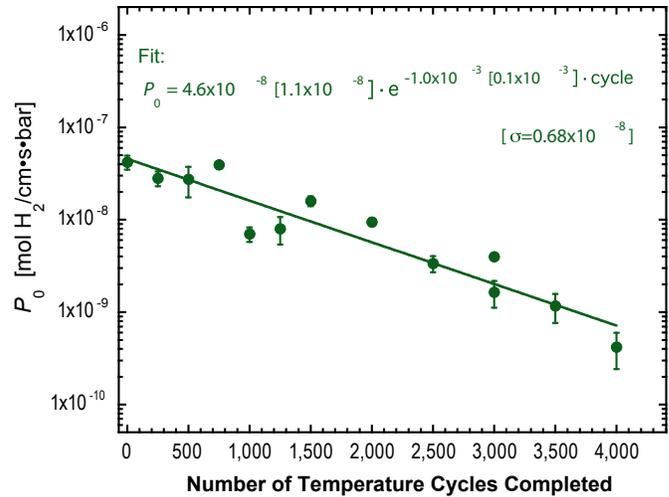

FIGURE 2b. The pre-exponential scaling factor P_0 also decreased through 4,000 temperature cycles, further evidencing small changes in polymer microstructure.

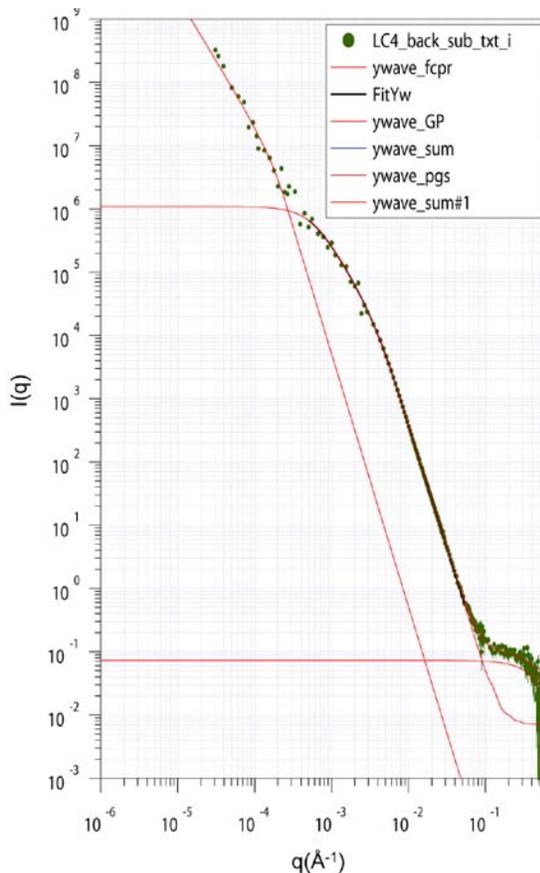

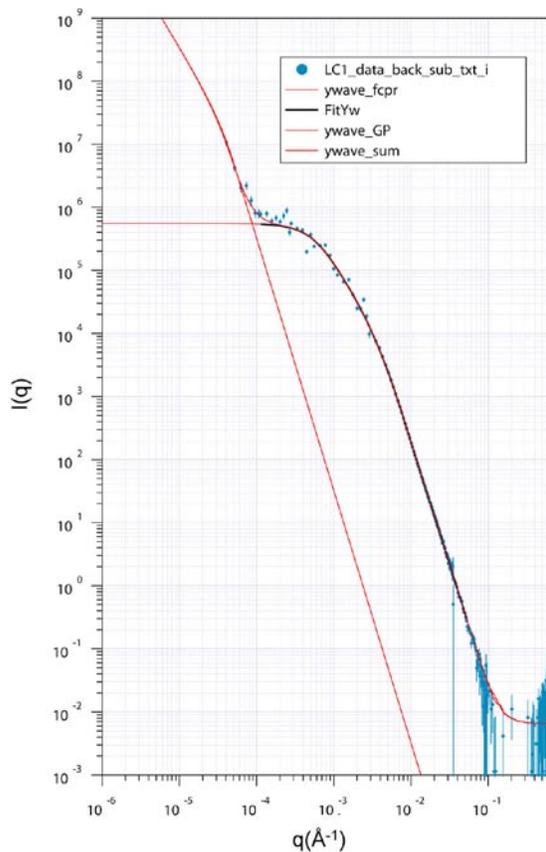

FIGURE 3. Neutron scattering data for Lincoln Composites tank liner specimens, before temperature cycling (left) and after 4,000 temperature cycles (right).

the polymer. We analyzed four HDPE tank liner specimens: 1) before temperature cycling, 2) after a few temperature cycles, 3) after 600 cycles, and 4) after 4,000 cycles. The

scattering data for the before-cycling and after-4,000-cycles specimens is shown in Figure 3. The scattering data was analyzed as follows [3]: the low- q section was fit using a

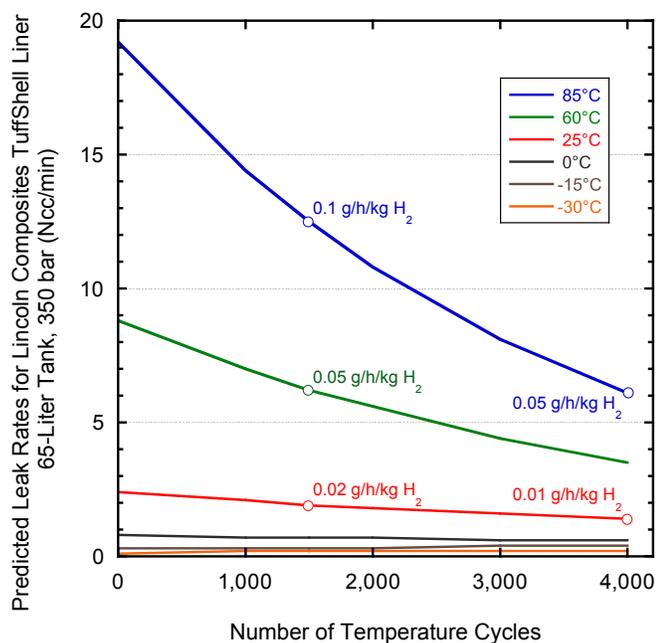

FIGURE 4. Predicted leak rate values for HDPE tank liner as a function of liner temperature and number of temperature cycles.

Guinier-Porod model, the central section was fit using a flexible cylinder with a polydispersed radius model (designed for treatment of polymers, see reference [3]), and the high- q section was fit to a polydispersed (Gaussian) sphere model. In the low- q section, the fit changes slope from -4 (Porod region) to -2 (Guinier region corresponding to plates or laminae). The transition from Porod to Guinier occurs with increasing number of temperature cycles. The presence of low- q scattering in the USANS data indicates the presence of large-scale ($>30\ \mu\text{m}$) scattering features that change significantly with long-term exposure to hydrogen or increasing number of temperature cycles or both. Similarly, the presence of high- q scattering appears only after temperature cycling.

Conclusions and Future Directions

We used the values of P_0 and E_A obtained from measurements during the temperature cycling to model the behavior of the permeation coefficients P as a function of T and the number of cycles. This modeling shows that at all temperatures the values of the hydrogen permeation coefficients decrease with cycle count, thus implying that the hydrogen leak rate of the tank liner should decrease with the number of temperature cycles.

To obtain a quantitative prediction of the leak rate for an actual tank liner, we used the dimensional specifications for a Lincoln Composites TUFFSHELL[®] hydrogen fuel tank rated for 350 bar service and with a volumetric capacity of 65.3 liters (water volume). The HDPE tank liner is cylindrical with nearly hemispherical end caps, and the

liner wall thickness is about 7 mm. We obtained a family of leak rate curves using the cycle-dependent permeation coefficients in an analytical expression for the tank leak rate. These curves are shown in Figure 4. In this analysis the tank leak rate remains below 75 normal cubic centimeters per minute (Ncc/min) at all temperatures for the duration of 4,000 temperature cycles. Furthermore, for all liner temperatures less than about 60°C, the loss of useable hydrogen remains below 0.05 g/h/kg H₂ for a fully filled tank, i.e., at a 350 bar pressurization.

For the next project year we have crafted a research plan that addresses the findings made in the present year. A second verification test on a fresh tank liner specimen is being carried out at 86 kPa following the same protocol. We will again perform some post-cycling analysis of the specimen to determine the type of structural changes that take place in the polymers. Differential scanning calorimetry measurements, SEM/BSE microscopy, transmission electron microscopy (using microtome sectioning), and perhaps some additional SANS/USANS (neutron scattering) will be used. This analysis will allow us to determine the implications of the structural changes during the lifecycle of the tank liner. Furthermore, we will expand the investigation beyond tests of the existing tank liner materials to future materials, as several tank manufacturers have recently introduced liners made from new less expensive and potentially higher performance (lower permeation) materials. Also under consideration is the need to adequately address the durability of the liner when it is bonded to the tank reinforcement. To this end we are developing a test plan for temperature cycling sectioned specimens from tank structures while they are differentially pressurized with hydrogen (high pressure on the liner side, atmospheric pressure on the outside of the reinforcement). Obtaining a better understanding the adhesion and interaction between the liner and composite matrix layer over the lifetime of the tank would be very valuable for a complete assessment of the lifecycle durability of the Type 4 storage tanks. This measurement will require a significant amount of collaboration with tank manufacturers to obtain their advisement on the testing procedure and their provision of tank sections.

Fiscal Year (FY) 2011 Objectives

- Develop an energy efficient recycling protocol for ammonia-borane (AB) from spent borate.
- Develop AB slurry-based subscale onboard hydrogen storage systems.
- Develop new noncatalytic methods for hydrogen generation from AB and water.

Technical Barriers

This project addresses the following technical barriers from the Storage section of the Fuel Cell Technologies Program Multi-Year Research, Development and Demonstration Plan:

- (A) System Weight and Volume
- (B) System Cost
- (J) Thermal Management
- (R) Regeneration Process
- (S) By-product/Spent Material Removal

Technical Targets

On-Board Storage	Units	2010/Ulimate	Purdue 2010
System Gravimetric Capacity	H ₂ wt%	4.5/7.5	11~14 (material)
Overall efficiency of off-board regeneration	%	>60	In process being optimized

FY 2011 Accomplishments

- AB thermolysis by-product, polyborazylene, was converted to ammonium borate [NH₄B(OH)₄], which was subsequently converted to trimethylborate.
- Reduced trimethylborate using diethylsilane with N¹,N¹,N²,N²-tetramethylethane-1,2-diamine (TMEDA) to TMEDA-bisborane complex.
- TMEDA-bisborane complex was converted to AB via transamination in 80% yield.
- Reduced ammonium borate to AB using lithium aluminum hydride with ammonium chloride.
- Analyzed gravimetric and volumetric capacities, H₂ release rates, and byproduct removal for liquid, solid and slurry AB-based systems.
- Addressed scientific and engineering issues with reactor capacities from 0.1 to 50 grams.
- Completed system engineering analysis of a baseline AB/ionic liquid slurry H₂ storage system.
- Obtained high H₂ yield (~14 wt%) and rapid kinetics for neat AB thermolysis under effective heat management at near proton exchange membrane fuel cell (PEMFC) operating temperatures (~90°C).
- Quantified ammonia formation in AB dehydrogenation processes and developed effective removal methods.

Introduction

This project allows the creation of a Hydrogen Research Laboratory in a unique partnership between Purdue University's main campus in West Lafayette and the Calumet campus. This laboratory is engaged in basic research in H₂ production and storage and has initiated engineering systems research with goals established as per the DOE Fuel Cell Technologies Program. Hydrogen production research of this project is reported in Purdue Hydrogen Systems Laboratory: Hydrogen Production.

A task of the H₂ storage work has been focused on finding energy efficient ways to recycle the AB thermolysis and hydrolysis by-products to AB. With the advantage of transportability of byproduct obtained from neat thermolysis

of AB and lessons learned with a gram scale neat AB reactor, we focused on the design, build and demonstration of a vehicle scale H_2 storage system. We have demonstrated that, with effective reaction heat management, high H_2 can be obtained from neat AB near PEMFC operating temperatures with rapid kinetics. We also established a physical property database for solvents and five solvents were selected as potential liquid carriers and mechanistic studies of AB dehydrogenation were conducted for each carrier. It has been reported that ammonia is generated during AB dehydrogenation. For use in PEMFCs, ammonia must be removed from the H_2 stream to less than ~ 10 ppm level. In our work, ammonia formation for AB dehydrogenation processes was quantified and effective methods for its removal were developed. Based on a neat AB thermolysis approach, we developed the concept of a continuous-flow system, and a prototype unit for laboratory evaluation was constructed. In this unit, the AB fuel feeding, reaction and spent fuel removal steps are integrated, and the reactor has provisions for utilization of waste heat from the PEMFC.

Approach

The spent fuel, ammonium borate or polyborazylene will be converted to triacyl- or trialkyl borates, which will provide molecules with weaker B-O bonds. The reduction of trimethyl borate in the presence of TMEDA, followed by the displacement of TMEDA using ammonia will lead to efficient ammonia borane regeneration.

We applied lessons learned on a multi-gram laboratory scale thermolysis batch reactor to design a cartridge based, self-sustained, and well-instrumented reactor system. The system was used to power a H_2 internal combustion engine (HICE) on a club car. The design uses cartridges that are pre-filled with the storage chemical before being loaded onto the vehicle. The reagent cartridges can be recycled off-board. The reactor system has the flexibility to accommodate slurries and other chemical hydrides. We analyzed a full-scale (for a 80 kW fuel cell) system using AB (80 wt%) and BmimCl (20 wt%) as the H_2 storage medium. The system consists of an AB slurry tank, a slurry pump, a slurry reactor, a H_2 buffer tank, a recuperator, a gas/liquid separator, a burner, and a heat transfer fluid (HTF) pump. To size these components, we used an in-house one-dimension computational fluid dynamics model to simulate thermo-chemical processes in the reactor and thermo-fluid processes in other components. The simulation was conducted to achieve a steady-state H_2 flow rate of 1.6 g/s. The H_2 buffer tank was sized to meet dynamic (unsteady state) requirements.

The neat AB thermolysis method for H_2 generation was investigated over a wide range of pressure, heating rate, AB density and insulation amount near PEMFC operating temperatures. For effective reaction heat management, some quartz wool was added at the top of the AB sample, which retains heat of exothermic thermolysis reaction while permitting product H_2 to flow. Mechanistic studies

(H_2 yield, thermal characteristics, NH_3 formation, etc.) of AB dehydrogenation for selected liquid carriers were conducted and further investigation was carried out to clarify the reaction mechanism using nuclear magnetic resonance, thermogravimetric analysis/differential scanning calorimetry, Fourier transform infrared and X-ray diffraction techniques. After cooling the reactor to room temperature at the end of the experiments, NH_3 was measured by various methods including Drager tubing, mass spectrometry and titration technique. A continuous-flow H_2 generation system was designed, constructed and tested.

Results

We have achieved the conversion of polyborazylene, obtained via the thermolysis of AB, to ammonium tetramethoxyborate $[NH_4B(OMe)_4]$ in the presence of methanol, followed by reduction to AB using lithium aluminum hydride and NH_4Cl in 81% yield. In an alternate protocol, ammonium tetramethoxyborate was converted to trimethyl borate in the presence of methanol. The reduction of trimethyl borate in the presence of TMEDA using diethylsilane resulted in the formation of bisamine borane complex in near quantitative yield (90%). The bisamine borane complex could be readily separated by filtration. The displacement of TMEDA from the amine borane complex was readily achieved using liquid ammonia to obtain 80% yield of AB (Figure 1). We have also reported the conversion of ammonium tetrahydroxyborate $[NH_4B(OH)_4]$, hydrolysis by-product of AB, to trimethyl borate without the conversion to boric acid. The reduction of trimethyl borate was achieved using either the silane protocol or via reduction to sodium borohydride with NaH and subsequent conversion to AB in the presence of ammonium sulfate (Figure 2). However, our attempted reduction of boron trifluoride and boron trifluoroacetate using a variety of silanes has not been successful.

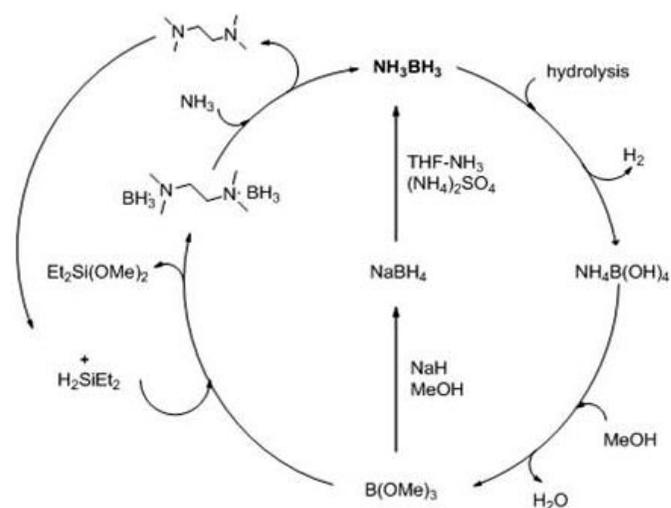

FIGURE 1. AB Hydrolysis Cycle: Recycling of Ammoniumborate

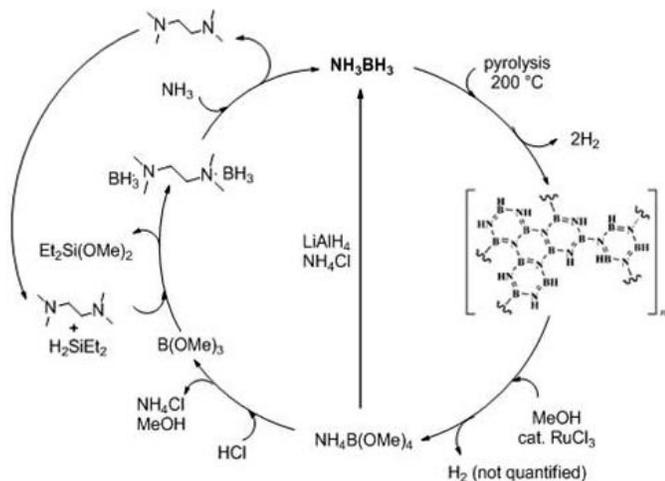

FIGURE 2. AB Thermolysis Cycle: Recycling of Polyborazylene

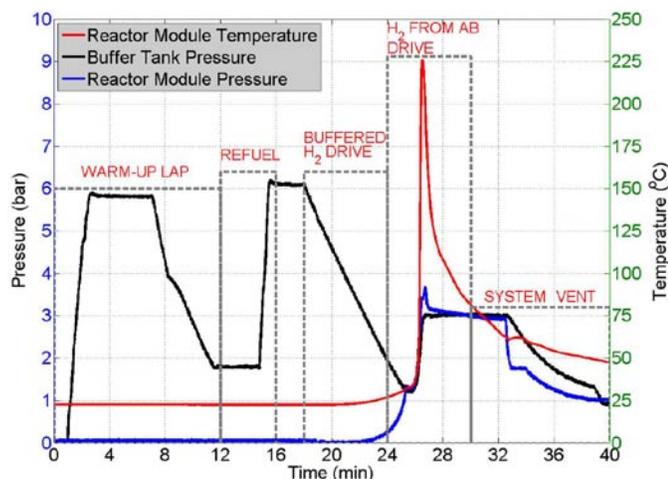

FIGURE 3. Pressure and Temperature Profile in the Club Car Vehicle Demonstration System during System Demonstration using Neat AB pellets

The vehicle-scale system consists of a HICE, four reactor modules, a modified engine exhaust, a buffer tank, and an onboard universal serial bus data acquisition system with a LabVIEW virtual interface for real time monitoring. The modified exhaust line of the HICE diverts using copper spiral tubing the exhaust to the reactor modules. Aluminum honeycomb in contact with the copper spiral further aids heat transfer to the reagent pellets. Figure 3 shows data from a typical experiment with ~50 g of AB pellets loaded in one module. The H₂ buffer tank is first filled to a pressure of ~6 bar from a commercial gas cylinder. Next the HICE is operated on the buffered H₂ and the exhaust is routed away from the reactor modules, allowing for system checks and warm-up. Once proper operation is confirmed, the buffer tank is refilled, and the engine is again operated with the exhaust routed to the first reactor module. The exhaust heat raises the AB temperature until dehydrogenation is achieved.

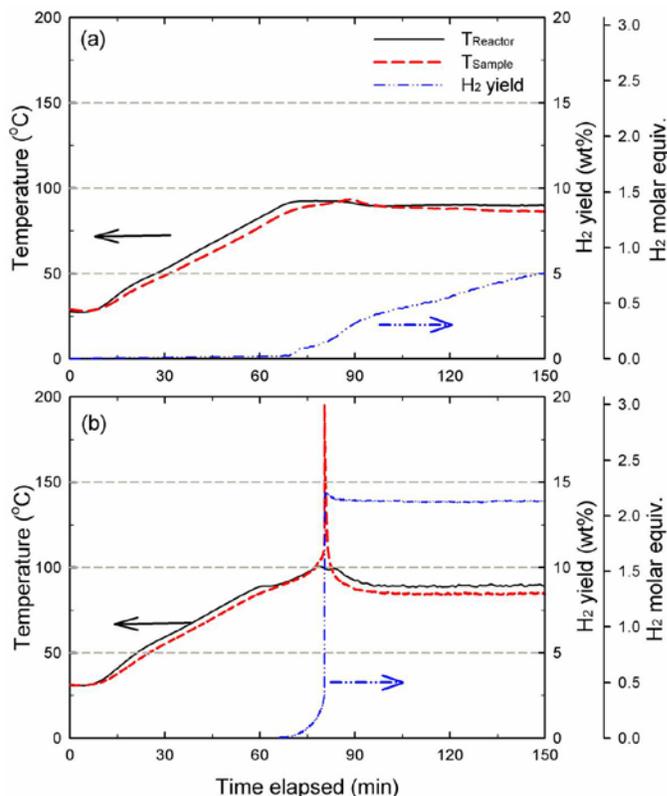

FIGURE 4. H₂ Yield, Temperature Profiles for Neat AB Thermolysis for $T_{SP} = 90^{\circ}\text{C}$, $P_i = 14.7$ psia and Heating Rate = $1^{\circ}\text{C}/\text{min}$ (a) without Quartz Wool (b) with Quartz Wool

The reaction leads to a sharp increase in the reactor temperature and increased pressure in the reactor module. The generated H₂ refills the buffer tank and is used to power the HICE. As designed, this process can be repeated with multiple reactor modules, leading to a self-sustained operation. Based on our engineering analysis of a baseline full-scale AB slurry system, a system of 81.2 kg total weight is required to store 5.6 kg usable H₂ or the system gravimetric H₂ storage capacity is 6.9 wt%. Among the total weight, the weight of the AB slurry is 58.5%, the weight of the HTF pump (on-shelf) is 19.7%, the weight of the slurry pump (on-shelf) is 11.7%, and the weight of other components is 10.1%.

We evaluated neat AB thermolysis near PEMFC operating temperature (90°C). For neat AB thermolysis without quartz wool, H₂ gradually evolved with time and only 5 wt% H₂ yield was achieved in 90 min as shown in Figure 4a. On the other hand, under effective heat management, H₂ yield ~14 wt% was achieved and stabilized quickly after sharp heat evolution (Figure 4b). To our knowledge, this value is higher than by any other method using AB at near PEMFC operating temperatures. A key factor is that effective reaction heat management is required to obtain sharp heat evolution, which plays a critical role in providing high H₂ yield. In addition, NH₃ in gaseous product was trace (~1 ppm), much less than that observed in neat AB thermolysis (~400 ppm) without heat

management. The solid products of neat AB thermolysis under heat management were found to be polyborazylene-like species (after 2 H₂ release from AB). At 85°C, similar H₂ yield was obtained from AB in all glycol-type liquid carriers (ethylene glycol, propylene glycol, trimethylene glycol and 1-3-butanediol) and slightly less in dimethyl sulfoxide. However, it was found that all the selected liquid carriers react with AB during dehydrogenation reaction and produce boric acid, which is not preferable from the spent fuel regeneration viewpoint. We demonstrated that NH₃ can be effectively removed by absorption in water, followed by adsorption on impregnated carbon. Our optimization results show that the weight required for the NH₃ removal system can be significantly reduced if water is recycled from the PEMFC. Further, since borazine hydrolyzes readily in water, our proposed method removes ammonia and any volatile borazine present. Based on neat AB thermolysis approach, a continuous-flow H₂ generation system was constructed and tested. Using this system, ~13.5 wt% H₂ yield (~2.1 H₂ molar equivalent) was obtained along with rapid H₂ evolution at 120°C.

Conclusions and Future Directions

We have developed an efficient protocol to prepare AB in large-scale from sodium borohydride and ammonium sulfate. We have developed four protocols to regenerate the spent material; (i) the AB hydrolysis by-product was converted to trimethyl borate and subsequently treated with diethylsilane in the presence of TMEDA to yield TMEDA-Bisborane complex which was converted to AB via transamination using ammonia (ii) the trimethyl borate was reduced to sodium borohydride which upon treatment with ammonium sulfate provided AB, (iii) the AB thermolysis by-product was converted to ammonium tetramethoxyborate and subsequently reduced to AB via silane protocol and (iv) AB was also regenerated from ammonium tetramethoxyborate in the presence of lithium aluminum hydride.

The vehicle-scale reactor system design addresses several engineering concerns with on-board chemical H₂ storage systems. It is compatible with a wide range of H₂ storage chemicals in pure or slurry form and can produce H₂ of sufficient purity for operation with a fuel cell. Future work includes design optimization with a COMSOL-based model, which incorporates reaction kinetics and heat and mass transfer and demonstration with a few other candidate chemicals for comparison. In on-going work we are (1) focusing on the experimental determination of the thermal properties of the ammonia borane pellets used in the vehicle-scale system, and (2) using the thermal property data together with the reaction kinetics data already obtained to improve the fidelity of the numerical model. The AB/BmimCl (80:20) slurry system can meet the 2015 system gravimetric H₂ storage capacity target (5.5 wt%) but can't meet the ultimate target (7.5 wt%). The present on-shelf pumps are too heavy and light HTF and slurry pumps

must be developed. In addition, effective spent fuel removal technologies must be developed in the near future.

Under effective reaction heat management, we obtained high H₂ yield (~14 wt%) from neat AB thermolysis at 14.7 psia and T_{sp} 90°C with rapid kinetics, without the use of either catalyst or chemical additives. To our knowledge, this value is higher than by any other method using AB at near PEMFC operating temperatures. We optimized and demonstrated that a sequence of absorption in water and adsorption on impregnated carbon captures ammonia, by-product of AB dehydrogenation, effectively from the product gas stream. Based on neat AB thermolysis, we developed and evaluated a laboratory-scale continuous-flow H₂ generation system. Using this system, ~13.5 wt% H₂ yield was obtained along with rapid H₂ evolution at 120°C. The increase of required reaction temperature, from 90 to 120°C, to rapidly provide high H₂ yield occurs due to heat loss from the reaction zone, and methods to minimize this loss will be investigated in the future.

Contract Number: DE-EE0000269

Project Start Date: November 25, 2009
Project End Date: October 31, 2011 - Project
delayed by 18 months; new End Date will be
determined by DOE.

*Congressionally directed project

Fiscal Year (FY) 2011 Objectives

- To carry out extensive research in fundamental physics and chemistry of glasses and of glass-based nano-crystalline materials.
- To fill gaps in the current understanding of these very complex materials.
- To shed more light on nucleation and crystallization phenomena in glass matrices, which could extend their technological applications.
- The ultimate vision of this project is to develop glass-based materials with structural properties that would make them of interest in H-storage.

Technical Barriers

This project is basic science in nature and involves fundamental research in physics and chemistry of glasses and of glass-based nano-crystalline materials. At this stage it does not address directly any Technical Barriers in hydrogen storage. In particular, hydrogen sorption and desorption tests or possibly kinetic measurements are not part of the project scope. However, the anticipated results could potentially be of interest for the following technical barriers from the Storage section (3.3) of the Fuel Cell

Technologies Program Multi-Year Research, Development and Demonstration Plan:

- (A) System Weight and Volume
- (B) System Cost
- (D) Durability/Operability

Technical Targets

This project is conducting studies of fundamental physics and chemistry of glasses and of glass-based nano-crystalline materials. In particular, hydrogen sorption and desorption tests or possibly kinetic measurement are not part of the project scope. However, insights gained from these studies could be applied toward the design and synthesis of new hydrogen storage materials that could potentially be applied towards the following DOE 2011 hydrogen storage technical targets:

- Weight and Volume: 0.045 kg H₂/kg system; 0.028 kg H₂/L system
- Cost: \$4/kWh net
- Energy density: 0.9 kWh/L

FY 2011 Accomplishments

- This brand new project required the establishment of two new laboratories: reconstruction/adaptation and purchase of state-of-the-art experimental instrumentation. This process took much longer than anticipated, due to technical issues, and resulted in an 18-month delay in terms of the start of research work.
- The project is composed of several experimental tasks which are sequential and depend on the completion of the new laboratories that is currently in its final phase.
- In the first 18 months of the project (January 2010 – June 2011) focus has been on laboratory space remodel, equipment purchase, installation and testing, hiring of personnel and literature studies.
- Two laboratories were established “from scratch”: the Materials Synthesis Lab combined with Materials at Extreme Environments Lab, as well as the Laser Spectroscopy Lab.
- Materials synthesis and characterization has begun.

Introduction

One of promising concepts for storing hydrogen are micro-containers built of glass and shaped into hollow microspheres. This fundamental research project explores

an extension of this concept where bulk glass materials are proposed to be employed as an inert storage medium. In general, the most desirable materials for hydrogen storage do not interact chemically with hydrogen and possess a high surface area to host substantial amounts of hydrogen. Glasses built of disordered networks with ample void spaces, permeable to hydrogen and glass-derived nanocomposites, hybrids of glass and nanocrystals, appear to be promising candidates for hydrogen storage. Other essential advantages of glasses include simplicity of preparation, flexibility of composition, chemical durability, non-toxicity and mechanical strength, as well as low production costs and environmental friendliness.

For the concept of glass materials to be practically implementable as hydrogen storage media, a considerable amount of fundamental research is still required into bulk glasses and their possible structural modifications. In this respect, this project is at the crossroads of glasses and glass-derived composite materials with structural properties that would make them promising candidates for potential use as hydrogen storage media.

Approach

This project is basic science in nature and it will challenge to extend the concept of using glass-based materials as hydrogen storage media. The focus will be on research of specific glass compositions with emphasis on their fabrication process and characterization using multi-technique experimental approach. The endeavor is to show ways how to tailor the structure of disordered amorphous networks in selected glasses by taking advantage of controlled nucleation and crystallization phenomena and by transforming them into glass-crystal hybrid complex nanocomposites.

Predominantly, this research will fill gaps in the current understanding of a very complex group of materials – glasses – and will shed more light on nucleation phenomena in glasses which will extend the existing variety of their technological applications. A far reaching goal of this project is the successful development of glass-derived composite materials with structural properties that would make them promising candidates for potential use as hydrogen storage media.

Results

The project begun technically only in January 2010 (availability of funds), with the establishment “from scratch” of two new experimental laboratories: Materials Synthesis Lab combined with Materials at Extreme Environments Lab, and the Laser Spectroscopy Lab. The process included reconstruction and adaptation of two lab spaces as well as purchase, installation and testing of state-of-the-art experimental instrumentation. Facility readiness is currently in its final stage, but - due to many technical issues out of

this team’s control - it resulted in an 18-month delay in terms of the start of research work.

Facility Readiness: Equipment Purchase and Laboratory Setup. This task of the project dealt with lab space reconstruction, which included work on electrical, heating, ventilation and air conditioning, plumbing and fireproofing in order to adapt the lab space to requirements of state-of-the-art new instrumentation. A large portion of the instrumentation had to be selected, negotiated and purchased. This included: a Raman spectrometer, combined with a confocal Raman microscope, a mid-temperature research furnace, optical tables, a multi-wavelength gas laser, a high-temperature research furnace and other minor equipment and lab supplies. After purchase, the instrumentation had to be installed, tested and calibrated in order to be ready for research use. In addition, since the instrumentation includes a spectrometer using a “Class IV” laser radiation source, several layers of physical and safety barriers had to be established to insure safe operation. In order to conform to institution and state and federal requirements Safety Rules, Dos and Don’ts and Use Rules had to be formulated to allow for the laser to be operated.

Experimental Work: Synthesis and Processing of Glass Materials. This task of the project deals with synthesis of the first batch of glass materials. This includes successful fabrication of few silica-based glasses with titanium, tantalum and gallium acting as network formers and/or network modifiers.

Experimental Work: Synthesis of Glass-Based Nanocrystalline Composites. Following the first glass synthesis, this task of the project consisted in successful fabricating of several nanocrystalline composites based on the above mentioned glass batches. This is an important achievement since there are only very few known glass compositions that allow for size-controlled formation of nanocrystals inside a glass matrix.

Conclusions and Future Directions

Technical delays associated with establishment of two new laboratories and purchasing of instrumentation were unavoidable, but difficult to deal with, since they delayed the start of experimental research work in this project.

Future work will involve materials synthesis and characterization:

- Continue synthesis and processing of glass materials.
- Continue synthesis of glass-based nanocrystalline composites.
- Perform micro-structural and nano-structural studies using a multi-technique approach.
- Determine microstructural changes produced in glass networks as a result of nucleation and growth of specific nanocrystalline phases.
- Comprehensive understanding of structure and packing density in the fabricated glasses.

Projected End Date: May 30, 2013

* Congressionally directed project

Fiscal Year (FY) 2011 Objectives

The objectives of this project are to:

- Identify complex hydrides that have the potential to meet DOE's goals for storage and demonstrate the optimum temperature and pressure ranges under a variety of conditions. Develop new catalysts and engineering techniques for increasing reaction rates and lowering reaction temperatures.
- Perform kinetic modeling studies and develop methods for improving kinetics and lowering reaction temperatures, thereby reducing refueling time.
- Extend the studies to include other complex hydrides, such as the $\text{LiNH}_2/\text{MgH}_2$ system, that have greater hydrogen storage potential.
- Extend studies to include carbon materials, metal organic frameworks (MOFs), and possibly other nanostructured and porous materials as potential hydrogen storage materials using hydrogen spillover.
- Design, fabricate and test a hydride-based hydrogen storage system for fuel cell applications in collaboration with our partners at the University of Delaware. Improve the rate at which the hydrogen gas can be charged into a hydride-based hydrogen storage tank, and to improve the hydrogen storage density.

Technical Barriers

This project addresses the following technical barriers taken from the Hydrogen Storage section of the Fuel Cell

Technologies Program Multi-Year Research, Development and Demonstration Plan:

- (A) System Weight and Volume
- (D) Durability/Operability
- (E) Charging/Discharging Rates

Technical Targets

This project is conducting fundamental studies of complex borohydride materials and other promising hydrogen storage materials. Insights gained from these studies will be applied toward the design and synthesis of hydrogen storage materials that meet DOE's 2015 goal of 5.5 weight percent hydrogen storage for the system. The following Table summarizes the targets.

TABLE 1. Technical Targets

Storage Parameter	Units	Target
System Gravimetric Capacity: Usable, specific-energy from H_2 (net useful energy/max system mass)	kWh/kg	1.5
System Volumetric Capacity: Usable energy density from H_2 (net useful energy/max system volume)	kWh/L	1.2
Storage System Cost (and fuel cost)	\$/kWh	6

FY 2011 Accomplishments

- The desorption properties for a series of $\text{MgH}_2/\text{LiBH}_4$ systems of compositions $\text{MgH}_2\text{-}2\text{LiBH}_4$, $\text{MgH}_2\text{-}4\text{LiBH}_4$, and $\text{MgH}_2\text{-}7\text{LiBH}_4$ have been determined. Temperature programmed desorption (TPD) results show that desorption temperatures increase with increasing amounts of LiBH_4 . Pressure-composition isotherm (PCI) results show that plateau pressures decrease with increasing amounts of LiBH_4 and the amount of hydrogen released increases with increasing amounts of MgH_2 .
- This work has shown that KH is a very effective catalyst for the desorption of hydrogen from the $\text{MgH}_2\text{-}2\text{LiNH}_2$ system.
- We have determined activation energies for the $\text{MgH}_2\text{-}2\text{LiNH}_2$ system with and without a KH catalyst using Kissinger analysis. Results show that the KH lowers the activation energy.
- The design, fabrication and demonstration of a hydride-based hydrogen storage system for fuel cells is underway. Results show that the heat removal rate can be increased by increasing the effective thermal conductivity by mixing the metal hydride with conductivity-enhanced materials such as aluminum foam or graphite.

Introduction

There has been considerable interest in complex hydrides such as borohydrides and amides because they have been determined to have great potential to meet DOE's goals for hydrogen storage. Current efforts in our research lab are focused on performing hydrogen storage studies on some new destabilized complex hydrides that have been predicted by first principles calculations to be suitable hydrogen storage materials. We will develop methods for the synthesis, characterization, and modeling of these new complex hydrides as well as developing new catalysts and engineering techniques for increasing reaction rates and lowering reaction temperatures. We will also extend these studies to include carbon materials, MOFs and possibly other nanostructured and porous materials as potential hydrogen storage materials. Once a suitable material has been identified for hydrogen storage it will be necessary to design, fabricate and test a hydride-based hydrogen storage system for fuel cell applications. Efforts are currently underway with a partner institution to design a hydrogen storage system and test it using a suitable material. This phase of the research will include using flow, reaction kinetics and thermal modeling, followed by system design, fabrication and performance evaluation.

Approach

To achieve the project objectives, new materials are being developed and characterized using a variety of techniques. Sample preparations prior to analysis were done in an argon-filled glove box (Vacuum Atmosphere Company). The hydrides were made by first ball milling the raw materials in a SPEX 8000 Mixer Miller and then directly combining them with hydrogen in a Sieverts apparatus. X-ray powder diffraction in a Panalytical X'pert Pro MPD Analytical X-Ray Diffractometer was used to confirm the formation of product and to determine phase purity. Thermogravimetric analyses (TGA) and TPD were used to determine the thermal stability and the hydrogen capacity of the mixtures. The TGA analyses were done in a Lab System-Diamond thermo-gravimetric/differential thermal analyzer. This instrument was placed inside of an argon-filled glove box so that samples can be analyzed with virtually no exposure to air and moisture. The TPD analyses were carried out in a PCI unit. The instrument was supplied by Advanced Materials Corporation. Kinetic measurements were done to determine the overall reaction rates.

Results

Previous studies have indicated that the $\text{MgH}_2/\text{LiBH}_4$ system has the potential to meet DOE's hydrogen storage goals. Therefore the desorption properties of a series of $\text{MgH}_2/\text{LiBH}_4$ systems were studied to determine how

suitable these materials were for hydrogen storage. The systems studied had compositions of $\text{MgH}_2\text{-}2\text{LiBH}_4$, $\text{MgH}_2\text{-}4\text{LiBH}_4$, and $\text{MgH}_2\text{-}7\text{LiBH}_4$. TGA measurements were done on each of the three systems to see if there was any correlation between temperature and composition. The results in Figure 1 show that desorption temperatures increase with increasing amounts of LiBH_4 . It was also of interest to determine the reversibility of these systems. To accomplish this, pressure-composition-isotherms were constructed for each system at several temperatures. The PCI results shown in Figure 2 demonstrate that plateau pressures decrease with increasing amounts of LiBH_4 and the amount of hydrogen released increases with increasing amounts of MgH_2 . Kinetics and modeling studies are presently underway to determine the rates of hydrogen release from these materials at constant pressure thermodynamic forces. We have already determined that the rate decreases with increasing amounts of LiBH_4 . It will

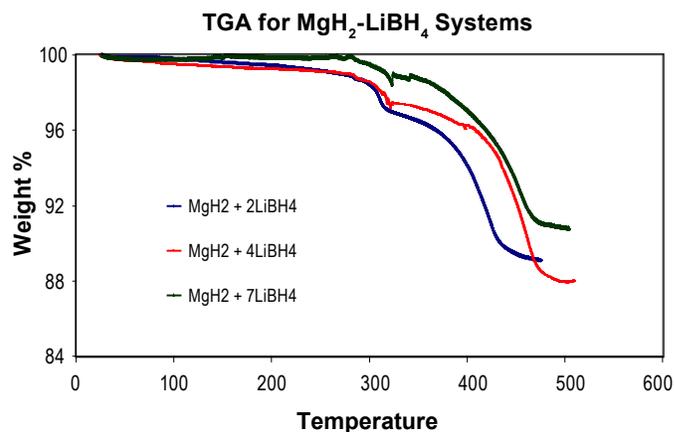

FIGURE 1. Thermal Gravimetric Analyses for Several $\text{MgH}_2\text{-LiBH}_4$ Systems. Desorption temperatures increase with increasing amounts of LiBH_4 .

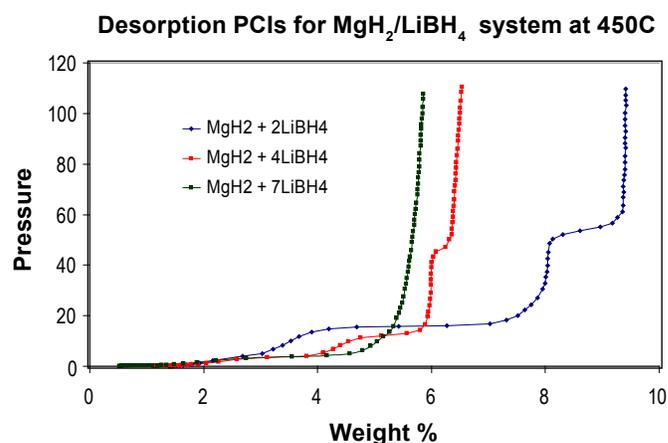

FIGURE 2. Desorption PCIs for $\text{MgH}_2/\text{LiBH}_4$ System at 450°C . Plateau pressures decrease with increasing amounts of LiBH_4 and the amount of hydrogen released increases with increasing amounts of MgH_2 .

also be useful to determine if the same or similar processes controls the reaction rates in all three systems.

There have been reports that systems based on $\text{MgH}_2/\text{LiNH}_2$ may also have the potential to meet DOE's goals for hydrogen storage. Therefore the desorption properties of a $\text{MgH}_2/2\text{LiNH}_2$ system were determined. PCIs were determined, with and without a KH catalyst, at several temperatures. The results show a well defined plateau region. Van't Hoff plots were used to determine the enthalpies of formation. Kinetics studies were done at constant pressure thermodynamic forces such that the ratio of the plateau pressure to the applied hydrogen pressure was held approximately constant at 10 in all cases. Results shown in Figure 3 indicate that the catalyzed system reacted much faster than the un-catalyzed system. Activation energies were determined by doing differential thermal analyses (DTA). Desorption temperatures were determined at several scan rates. DTA curves showed that the desorption temperatures increase with increasing scan rates. These results were used to construct Kissinger plots. The activation energies for the catalyzed and uncatalyzed systems were 106 and 116 kJ/mol respectively. As expected, the catalyzed system had lower activation energy than the uncatalyzed one.

Another project is underway entitled "Design, Fabrication and Demonstration of a Hydride-Based Hydrogen Storage System for Fuel Cell Applications". The overall objective is to improve the rate at which the hydrogen gas can be charged into a hydride-based hydrogen storage tank, and to improve the hydrogen storage density. A mathematical model is being used to predict the temperature at selected locations within the storage tank. A series of experiments have been performed to compare

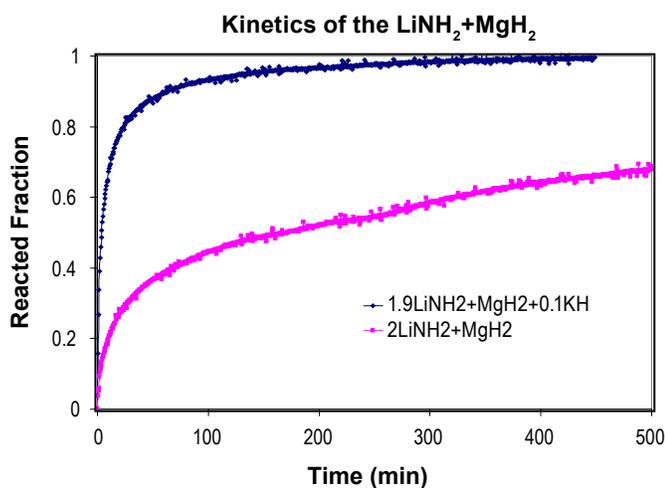

FIGURE 3. Kinetics of the $\text{MgH}_2\text{-}2\text{LiNH}_2$ System. Measurements were done at 210°C and the ratio of the plateau pressure to the applied hydrogen pressure was set at 10. The system containing 3.3 mol% KH catalyst reacts about 10 times faster than the un-catalyzed system. The un-catalyzed system required more than 3,000 min to reach completion.

the temperature at these locations with the numerically predicted value. Three experiments in Figure 4 were done to compare the temperature in the storage tank to that predicted by a numerical model. The results for experiment agreed to within ± 5 degrees. It has been determined that the heat removal rate can be increased by (i) increasing the effective thermal conductivity by mixing the metal hydride with conductivity-enhanced materials such as aluminum foam or graphite, (ii) optimizing the shape of the tank, and (iii) introducing an active cooling environment instead of relying on natural convection. All of this work is being done by our partners at the University of Delaware.

Conclusions and Future Directions

- This work has shown that several destabilized borohydride systems based on $\text{Li}(\text{BH}_4)_2/\text{MgH}_2$ can absorb hydrogen reversibly but the desorption temperatures increase and hydrogen holding capacities decrease as the relative amount of LiBH_4 increases. We have also determined that KH is a very effective catalyst for the desorption of hydrogen from the $\text{MgH}_2\text{-}2\text{LiNH}_2$ system.
- In the FY 2011-2012, the following work is planned:
 - Continue the desorption studies on several $\text{MgH}_2/\text{Amide}$ based destabilized systems using techniques such as ball milling, PCI measurements, XRD, TPD, TGA, kinetics and modeling.
 - Perform kinetics and modeling studies on the $\text{MgH}_2/\text{LiBH}_4$ systems at constant pressure driving forces in order to establish the rate-controlling process.

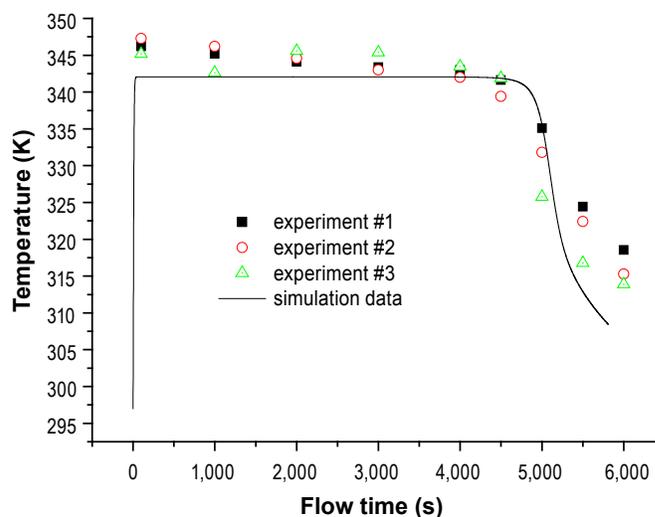

FIGURE 4. A mathematical model was used to predict the temperature at selected locations within the storage tank. Three experiments were done to compare the temperature in the storage tank to that predicted by a numerical model. The results for experiment agreed with the predicted values to within ± 5 degrees.

- Use techniques such as residual gas analysis to determine if dehydrogenation is accompanied by the release of other gaseous byproducts.
- Continue with the design, fabrication and demonstration of a hydride-based hydrogen storage system that is on-going with our collaborators at the University of Delaware.

V. FUEL CELLS

V.0 Fuel Cells Sub-Program Overview

The Fuel Cells sub-program supports research, development, and demonstration of fuel cell technologies for a variety of stationary, transportation, and portable applications, with a primary focus on reducing cost and improving durability. These efforts include research and development (R&D) of fuel cell stack components, system balance-of-plant (BOP) components, and subsystems, as well as system integration. The sub-program seeks a balanced, comprehensive approach to fuel cells for near-, mid-, and longer-term applications. Existing early markets and near-term markets include portable power, backup power, auxiliary power units, and specialty applications such as material handling equipment. Mid- and longer-term applications with more stringent technical and cost requirements include distributed power generation (e.g., combined heat and power [CHP] for residential and commercial applications) and transportation (e.g., light-duty vehicles and transit buses). The sub-program's portfolio of projects covers a broad range of technologies, including polymer electrolyte membrane fuel cells, direct methanol fuel cells, alkaline fuel cells, and solid oxide fuel cells (SOFCs).

The Fuel Cells sub-program's tasks in the *Fuel Cell Technologies Program Multi-Year Research, Development and Demonstration Plan* are organized around development of components, stacks, sub-systems, and systems; supporting analysis; and testing, technical assessment, and characterization activities. Task areas for fuel cell system and fuel processor sub-system development for stationary power generation applications are included, as are those for early market fuel cell applications, such as portable power, and for the development of innovative concepts for fuel cell systems.

Goal

The sub-program's goal is to advance fuel cell technologies for stationary, portable, and transportation applications to make them competitive in the marketplace in terms of cost, durability, and performance, while ensuring maximum environmental and energy-security benefits.

Objectives¹

The sub-program's key objectives include:

- By 2015, develop a fuel cell system for portable power (<250 W) with an energy density of 900 Wh/L.
- By 2017, develop a 60% peak-efficient, direct-hydrogen fuel cell power system for transportation, with 5,000-hour durability, that can be mass produced at a cost of \$30/kW.
- By 2020, develop distributed generation and micro-CHP fuel cell systems (5 kW) operating on natural gas or liquefied petroleum gas that achieve 45% electrical efficiency and 60,000-hour durability at an equipment cost of \$1,500/kW.
- By 2020, develop medium-scale CHP fuel cell systems (100 kW–3 MW) that achieve 50% electrical efficiency, 90% CHP efficiency, and 80,000-hour durability at a cost of \$1,500/kW for operation on natural gas and \$2,100/kW when configured for operation on biogas.
- By 2020, develop a fuel cell system for auxiliary power units (1–10 kW) with a specific power of 45 W/kg and a power density of 40 W/L at a cost of \$1,000/kW.

Fiscal Year (FY) 2011 Technology Status

The need for cost reductions and improvements in durability continue to be the key challenges facing fuel cell technologies. In addition, advances in air, thermal, and water management are necessary for improving fuel cell performance; some stationary applications would benefit from increased fuel flexibility, and, while fuel cells are approaching their targets for power density and specific power, further progress is required to achieve system packaging requirements necessary for commercialization.

One of the most important metrics is the projected high-volume manufacturing cost for automotive fuel cells—the Program tracks this on an annual basis. The 2011 estimate of this cost is \$49/kW, which represents

¹ Note: Targets and milestones are under revision; therefore, individual progress reports may reference prior targets.

a 33% decrease since 2008 and an 82% decrease since 2002, as depicted in Figure 1. The 33% decrease in projected cost since 2008 stems in part from a reduction in precious grade metal loading and an increase in cell power density, allowing the design of smaller and less expensive stacks. The 2011 cost analysis estimated the cost of the fuel cell stack to be \$22/kW. BOP cost has also been reduced during this time. Major sources of the reduction in BOP cost include reconfiguration of the ejector system based on stakeholder input, redesign of the system controller, and reduction of the radiator size. The reduced radiator size was enabled by improvements in stack components, allowing a higher stack operating temperature.

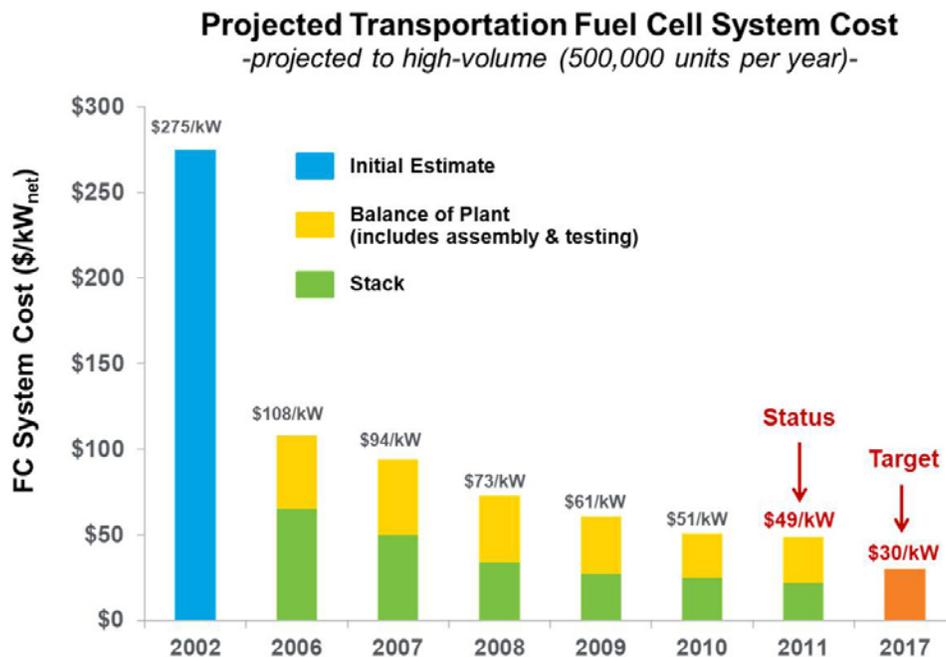

FIGURE 1. Current Modeled Cost of an 80-kW Automotive Fuel Cell System Based on Projection to High-Volume Manufacturing (500,000 units/year)²

FY 2011 Accomplishments

In FY 2011, continued progress was made toward meeting 2017 technical and cost targets. Notable technological advances in several component areas have led to significant improvements in performance and durability, with decreased cost. Key advances in FY 2011 include the following:

- Nano-segregated binary and ternary catalysts demonstrated performance more than 6X that of platinum:** Following on the discovery of the exceptionally high activity of the Pt₃Ni(111) surface for the oxygen reduction reaction, which has specific activity two orders of magnitude higher than that of Pt/C,³ Argonne National Laboratory (ANL) is working to develop nanosegregated Pt/Ni catalysts that can achieve similar activity in a catalyst suitable for incorporation in fuel cells. Pt/Ni catalysts synthesized thus far at ANL have mass activity six times that of Pt/C (Figure 2), approaching the DOE target activity of 0.44 A/mg. The Pt/Ni catalysts also have better durability than conventional Pt/C. ANL is also developing a variety of ternary catalysts in which an Au core is encapsulated by an FePt shell. These ternary catalysts also exhibit better activity and stability than conventional Pt/C.

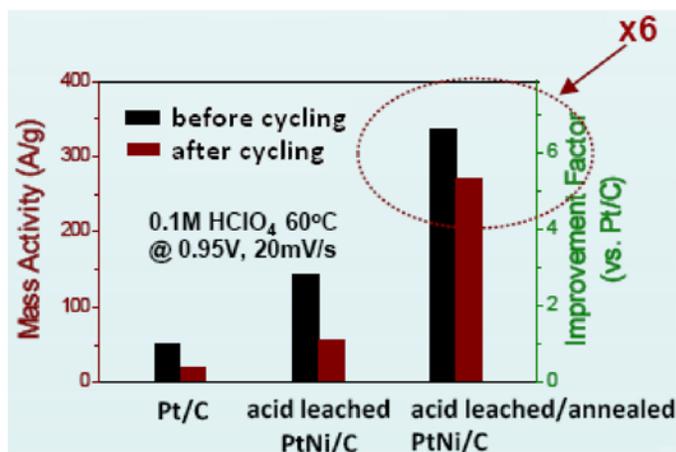

FIGURE 2. Mass Activity of Several Pt-Based Catalysts for the Oxygen Reduction Reaction⁴

- New cathode and anode catalysts demonstrated durability under startup/shutdown:** Significant progress has been made in addressing degradation that can occur under startup, shutdown, and fuel-starvation conditions. Work led by 3M has resulted in development of new cathode and anode catalysts to increase durability.⁵ 3M has incorporated a highly active and highly durable oxygen evolution catalyst on the cathode, based on Ru and Ir. By enhancing oxygen evolution, these catalysts suppress excursions to high voltage, and thus mitigate corrosion of catalysts and supports. In collaboration with 3M, ANL has developed calixarene-modified anodes, on which the oxygen reduction reaction is suppressed without inhibiting hydrogen oxidation. Use of the modified cathode and anode catalysts has enabled successful achievement of 10,000 simulated startup/shutdown cycles with only 2 $\mu\text{g}/\text{cm}^2$ more precious grade metal content, in addition to the 0.15 mg/cm^2 total Pt content (Figure 3).

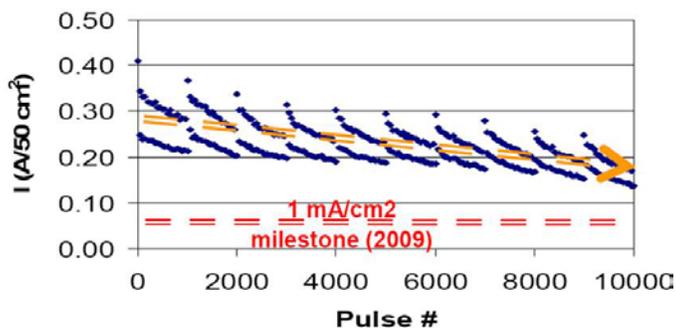

FIGURE 3. Oxygen Evolution Performance Of A Modified Cathode Catalyst – Performance Remains Higher than the Target even after 10,000 Cycles⁶

- Degradation studies enabled design of more durable electrodes:** Los Alamos National Laboratory has demonstrated the relationship between electrode structure and cell durability.⁷ They found that the degree of ordering and agglomeration of perfluorosulfonic acid (PFSA) ionomer during electrode preparation is

⁴ Ibid.

⁵ Radoslav Atanasoski et al., “Durable Catalysts for Fuel Cell Protection During Transient Conditions,” 2011 DOE Hydrogen and Fuel Cells Program Annual Merit Review Proceedings, http://www.hydrogen.energy.gov/pdfs/review11/fc006_atanasoski_2011_o.pdf.

⁶ Ibid.

⁷ Rod Borup et al., “Durability Improvements Through Degradation Mechanism Studies,” 2011 DOE Hydrogen and Fuel Cells Program Annual Merit Review Proceedings, http://www.hydrogen.energy.gov/pdfs/review11/fc013_borup_2011_o.pdf.

related to the long-term stability, with a higher degree of ordering correlating with lower stability. They also discovered that ionomer aggregation in solution leads to poorer mechanical properties in cast ionomer films, suggesting that the observed electrode stability differences are related to the mechanical properties of the ionomer in the electrode. Electrodes prepared from glycerol-based inks, in which little ionomer agglomeration occurs, demonstrated high stability, with less than 30 mV loss at 0.8 A/cm² after 70,000 cycles, exceeding the DOE target of 30,000 cycles. In contrast, electrodes prepared from water/alcohol-based inks, in which ionomer agglomeration occurs, were shown to suffer from severe degradation.

- **Innovative membranes demonstrate high conductivity at low relative humidity:** Progress in development of perfluoroimide acid (PFIA) membranes has enabled 3M to meet most DOE targets for high-temperature membranes, and 3M is close to fulfilling the final target of 0.02 ohm-cm² area specific resistance at 120°C and 40 kPa of water vapor.⁸ The 3M PFIA ionomer is related to conventional PFSA ionomers, but it incorporates two superacid sites per side chain—an imide acid site in the middle of the chain, and a sulfonic acid site at the end of the chain. This configuration allows use of a lower equivalent weight ionomer with a more highly acidic acid group. The multi-acid side chain approach allows preservation of the perfluorinated backbone crystallinity at lower equivalent weights than with conventional PFSA. This enables higher conductivity under dryer conditions without sacrificing mechanical properties, and it is expected to lead to better performance and durability than conventional PFSA.
- **Performance and durability of SOFC systems improved:**
 - Reversible SOFCs under development at Versa Power Systems have made significant progress, meeting resistance, degradation, and current density targets.⁹
 - In addition to the increase in SOFC system power density achieved in FY 2010, Acumentrics has demonstrated increased durability, with more than 12,000 hours of operation.¹⁰ Acumentrics also increased system electrical efficiency from 35% to 40%, through enhancements made in reforming technology and generator design. These advances represent a significant step toward production of an SOFC system for widespread commercialization.

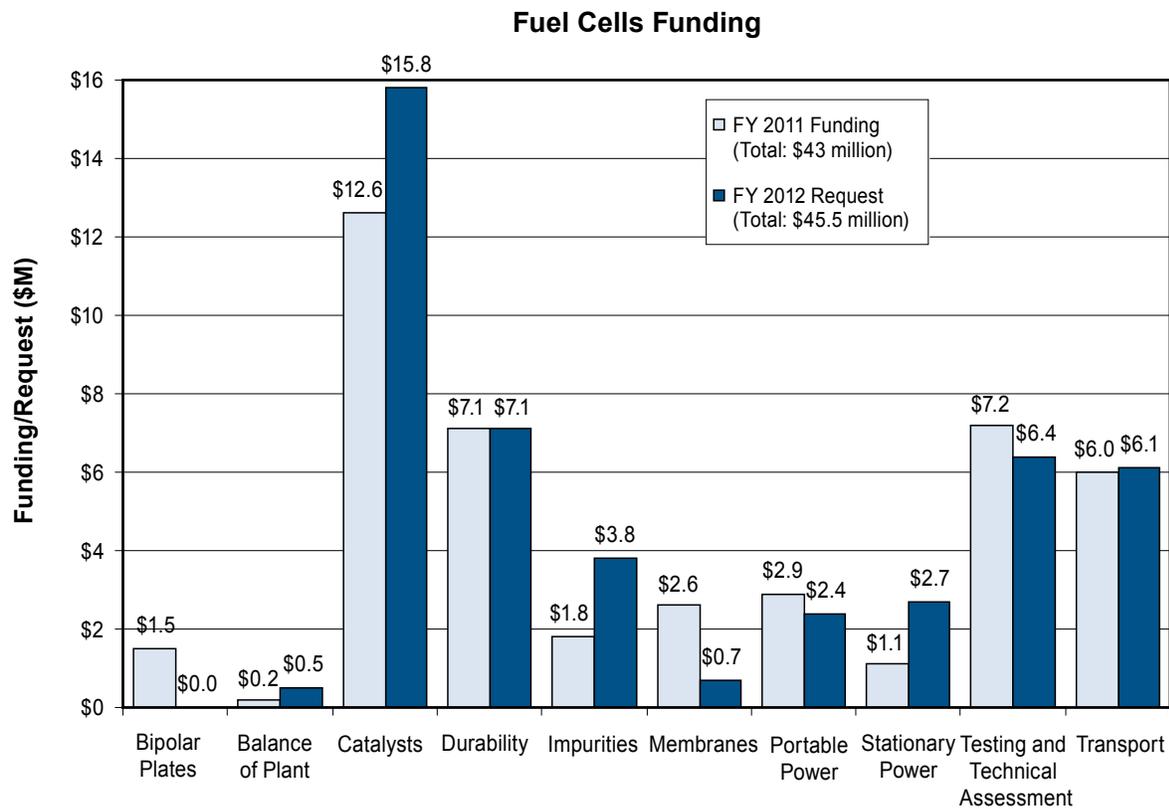

Budget

The President's FY 2012 budget request calls for approximately \$45.5 million for the Fuel Cells sub-program. The following figure shows the budget breakdown by R&D area for the FY 2011 congressional appropriation of \$43 million and the FY 2012 budget request. The sub-program continues to focus on reducing costs and improving durability with an emphasis on fuel cell stack components. The funding profiles for FY 2011 and the FY 2012 request are very similar, with some projects in membranes and bipolar plates ending in FY 2011.

FY 2012 Plans

In FY 2012, the Fuel Cells sub-program will continue R&D efforts on fuel cells and fuel cell systems for diverse applications, using a variety of technologies (including polymer electrolyte membrane, solid oxide, and alkaline fuel cells) and a range of fuels (including hydrogen, diesel, natural gas, and bio-derived renewable fuels). Support will continue for R&D that addresses critical issues with electrolytes, catalysts, electrodes, and modes of operation. The sub-program will also continue its emphasis on science and engineering at the cell and stack level and on integration and component interactions at the system level. Significant emphasis will be placed on BOP component R&D (such as humidifiers and air compressors) that can lead to lower cost and lower parasitic losses. Ongoing support of modeling will guide component R&D, benchmarking complete systems before they are built and enabling exploration of alternate system components and configurations. Cost analysis efforts have been expanded to include distributed power generation systems (including CHP) and systems for emerging markets for a variety of fuel cell technologies; detailed results of these analyses are expected in FY 2012.

FY 2012 will see the continuation of most existing projects, as well as the initiation of new projects. A fuel cell R&D solicitation closed in FY 2011, and a small number of new R&D projects from the solicitation are expected to begin in FY 2012, subject to appropriations.

E-mail: Kathi.Epping@ee.dog.gov

Project Start Date: July, 2009

Project End Date: Project continuation and direction determined annually by DOE

- Maximum projected operation hours to 10% voltage drop ~12,000 hours.
- Backup
 - Average projected operation hours to 10% voltage drop ~3,300 hours.
 - Maximum projected operation hours to 10% voltage drop ~7,000 hours.
- Forklift
 - Average projected operation hours to 10% voltage drop ~13,000 hours.
 - Maximum projected operation hours to 10% voltage drop ~21,000 hours.
- Stationary
 - Average projected operation hours to 10% voltage drop ~17,000 hours.
 - Maximum projected operation hours to 10% voltage drop ~41,000 hours.

Fiscal Year (FY) 2011 Objectives

- Benchmark state-of-the-art fuel cell durability.
- Leverage analysis experience from Fuel Cell Vehicle Learning Demonstration project.
- Collaborate with key fuel cell developers on the analysis.

Technical Barriers

This project addresses the following technical barriers from the Fuel Cells section of the Fuel Cell Technologies Program Multi-Year Research, Development and Demonstration Plan:

(A) Durability

Technical Targets

This project is conducting an independent assessment of current laboratory fuel cell stacks and systems durability. The analysis, applied uniformly on all data sets, studies the projected operation time to 10% voltage drop. All results are aggregated to protect proprietary information and reported on by the expected application.

FY 2011 Accomplishments

- Published three composite data products (CDPs) on operation time and projected operation time to 10% voltage drop statistics, projected operation time sensitivity to voltage drop levels, and comparison of automotive lab and field durability projections:
 - Automotive
 - Average projected operation hours to 10% voltage drop ~4,000 hours.

- Analyzed fuel cell stack and system data in four application categories and from eight fuel cell developers.
- All data included many proton exchange membrane (PEM) fuel cells and solid oxide fuel cells (SOFCs) of full active area short stacks and full stacks with systems
- Shared all detailed data analysis results with data providers.

Introduction

The DOE has funded significant research and development activity with universities, national laboratories, and the fuel cell industry to improve market competitiveness of fuel cells. Most of the validation tests to confirm improved fuel cell stack performance and durability (market competitiveness) are completed by the research organizations themselves. Although this allows the tests to be conducted by the developers most familiar with their specific technology, it also presents a number of challenges in sharing progress publicly because test conditions and data analysis take many forms, and data collected during testing are often considered proprietary.

NREL is benchmarking the state-of-the-art fuel cell performance, specifically on durability, through independent assessment of current laboratory data sets. The data processing, analysis, and reporting capitalize on capabilities developed in DOE's Fuel Cell Vehicle Learning Demonstration. Fuel cell stack durability status is reported annually and includes a breakdown of status for different applications. A key component of this project is the collaborative effort with key fuel cell developers to

understand what is being tested in the lab, study analysis results, and expand the included data sets.

Approach

The project involves voluntary submission of data from relevant fuel cell developers. We are contacting the fuel cell developers for multiple fuel cell types to either continue or begin a data sharing collaboration. A continuing effort is to include more data sets, types of fuel cells, and developers.

Raw and processed data are stored in NREL's Hydrogen Secure Data Center. Processing capabilities are developed or modified for new data sets and then included in the analysis processing of NREL's Fleet Analysis Toolkit. The incoming raw data may be new stack test data, or it may be continuation of data that has already been supplied to NREL. After the raw data are processed, the results are analyzed with particular attention to durability and operating conditions. Each individual data set has a set of data figures that are shared with the data provider and used to create the CDPs. CDPs are designed to report on the technology status without revealing proprietary information.

Results

This fuel cell stack durability analysis grew in the number of data sets, applications, fuel cell types, and the details published. Results published in June 2010 were the

second update for this analysis effort, and the next analysis update is scheduled for July 2011. In the last published data set, four applications were covered, eight fuel cell developers supplied data (more than one data set in many cases), and the data sets covered PEM and SOFC stack testing. The analyzed data sets are from lab testing of full active area short stacks (e.g, stacks with fewer cells than the expected full power stack) and test systems with full power stacks. The data sets also vary from one to the other in how the stack/system was tested. Data was generated between 2004 and early 2010 from different testing methods that included constant load, transient load, and accelerated testing. The variability in test conditions and test setups create a group of data that can be difficult to compare. Additional breakdown of the data sets is an important aspect of future work and is dependent on the accumulation of more data sets in order to not reveal data supplier contribution to the results or proprietary data.

Fuel cell durability is studied at a design specific current point and measured against a target of 10% voltage drop from beginning of life. The 10% voltage drop metric is used for assessing voltage degradation with a common measurement, but the metric may not be the same as end-of-life criteria and does not address catastrophic failure modes. Figure 1 is an aggregated set of results separated by application and identifies the percentage of short stacks and how many data sets are still operating (at the time of the results) for each application. Each application has the average, maximum, 25th and 75th percentiles values

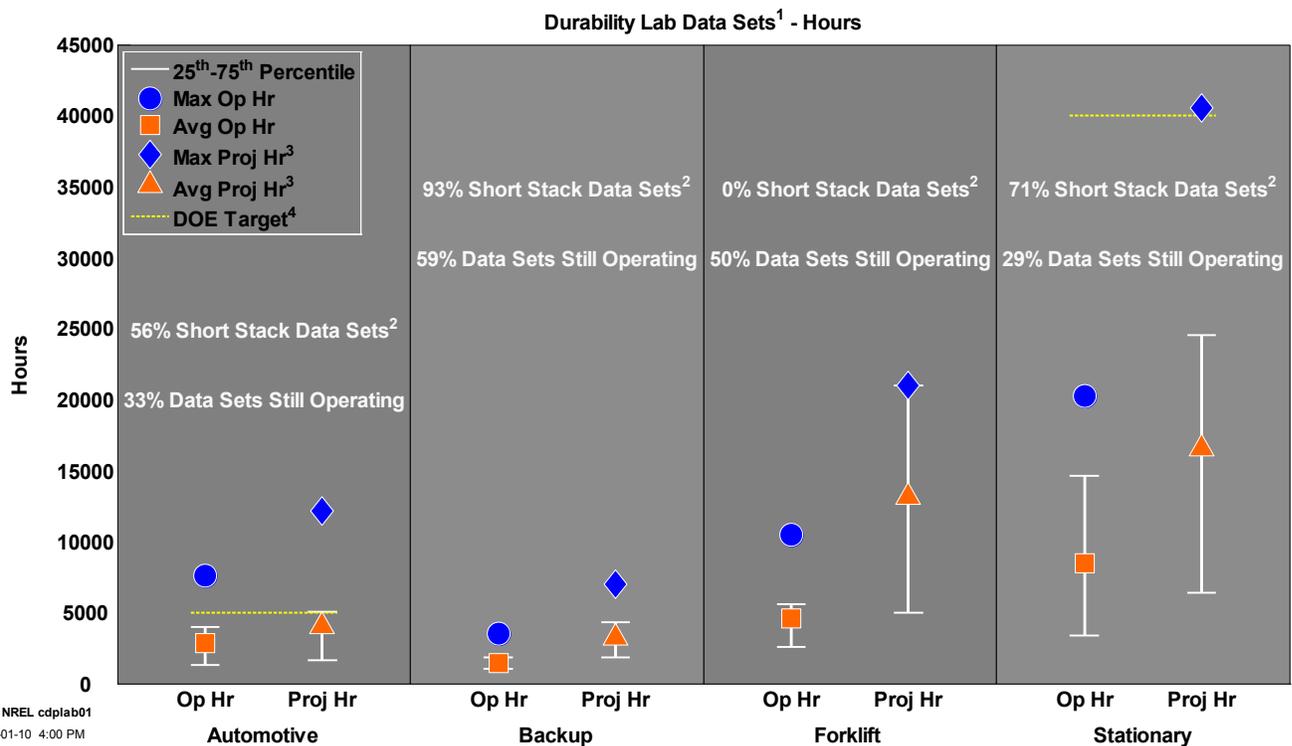

FIGURE 1. Fuel Cell Operation Hours and Projection Hours to 10% Voltage Drop by Application

identified for the operation hours and the projection hours to 10% voltage drop. Table 1 summarizes the average values highlighted in Figure 1.

TABLE 1. Summary of Average Operation Hour and Average Projection Hour to 10% Voltage Drop by Application

Application	Average Operation Hour	~Average Projection Hour to 10% Voltage Drop
Backup	1,424	3,300
Automotive	2,865	4,000
Forklift	4,573	13,000
Stationary	8,438	17,000

The 10% voltage drop level is not necessarily a measurement for end-of-life or even significant reduction in performance. Figure 2 depicts the sensitivity of each application’s projected hours to a varying voltage degradation level. Each curve represents the average for each application, but the graph does not imply that all stacks will (or do) operate at these voltage degradation levels. In the analysis, the projection may be limited by the demonstrated operation hours to minimize extrapolations. This limit is why the application average curves flatten out at the higher voltage degradation levels.

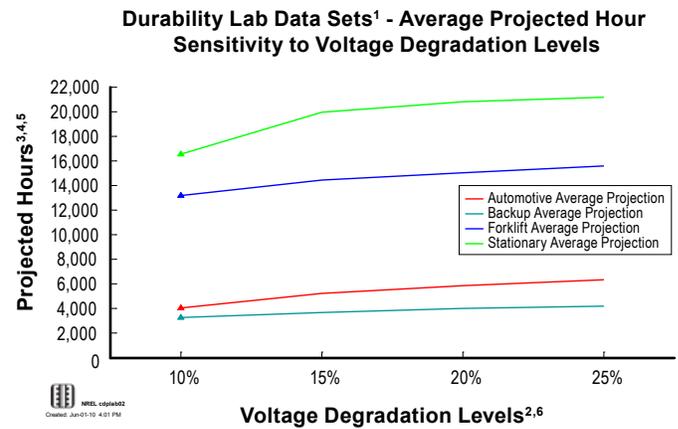

FIGURE 2. Durability Projection Sensitivity to Measured Voltage Degradation Levels

Another avenue for analysis is the comparison of data generated from testing in the lab and real-world operation. Figure 3 is the first phase in this comparison analysis. In addition to this analysis of lab data sets, NREL is also studying the performance of many fuel cell applications in real-world settings. Improvements were demonstrated in the field for Generation 2 fuel cell vehicles as seen in Figure 3. A large improvement is also observed when comparing the

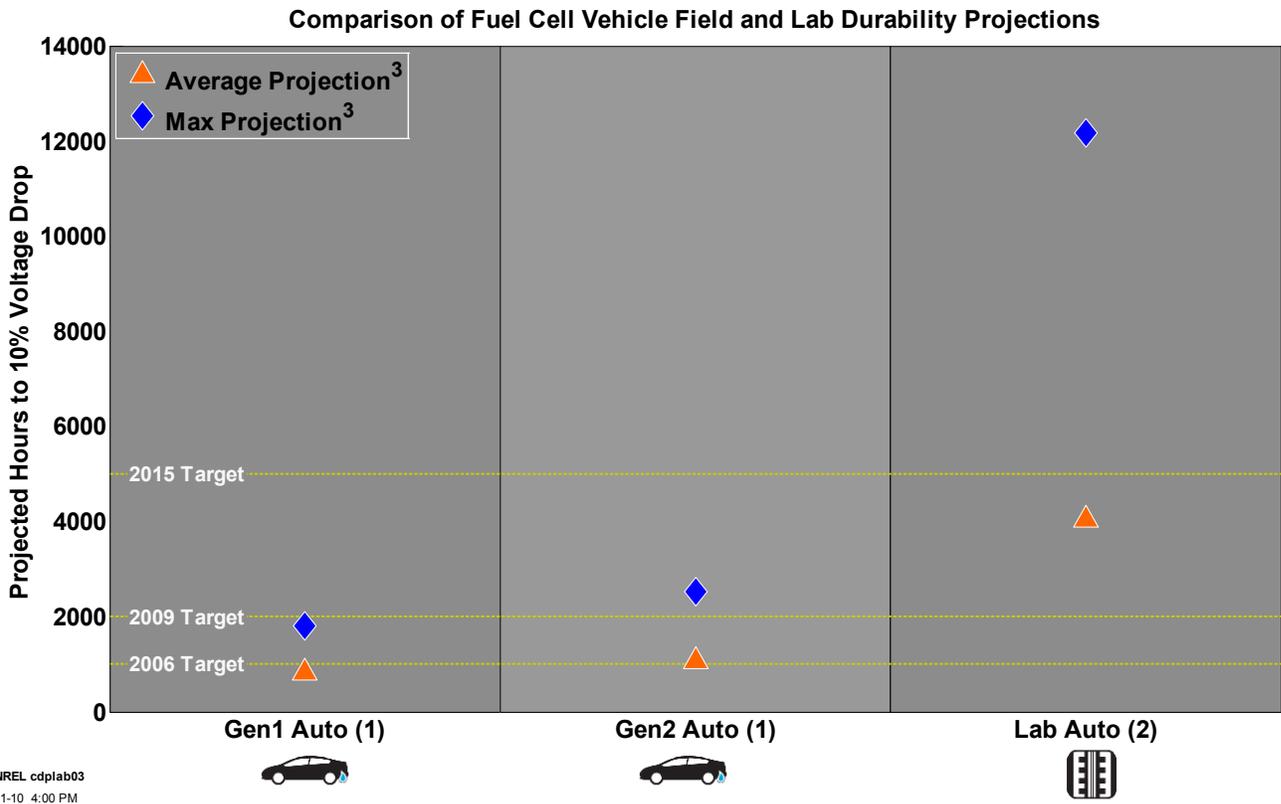

FIGURE 3. Automotive Fuel Cell Durability Projection Comparison between Lab and Field Data

Generation 2 field data with the lab data results. There are a number of potential explanations for the improvements: 1) improvements in technology generation and performance; 2) testing conditions; 3) 56% of the lab data sets are short stacks, and none are integrated into a vehicle; and 4) data providers in the lab category are not all the same as the data providers for the field category.

Conclusions and Future Direction

This analysis effort highlights the positive progress made by the fuel cell developers with the state-of-the-art fuel cell stacks and applies a uniform analysis method to aggregate and report on the results. Results highlight the difference in performance between applications to meet specific market needs as well as the needs for expansion of the results for more details and categories, such as accelerated testing. Data are supplied voluntarily and an important aspect of this project is the collaboration effort to study the data, project durability, and report on the results without revealing proprietary data. Eight fuel cell developers have already supplied data and other fuel cell developers are expected to add data for the next analysis and reporting cycle.

Planned future work is as follows:

- Update analysis results through published CDPs (July 2011).
- Continue collaboration and data sharing with existing data suppliers and other fuel cell developers (on-going).
- Accumulate more data to allow for new and more detailed CDPs (on-going).
- Expand comparison of durability projections between lab data and field data (July 2011).

 No. DE-AC36-08GO28308

Project Start Date: July 8, 2010
 Project End Date: May 8, 2012

Fiscal Year (FY) 2011 Objectives

- Prepare a written report documenting the results and assumptions used in the 2010 80 kW automotive fuel cell system cost analysis.
- Continue cost analysis of automotive fuel cell systems and update the cost estimates for 2011 technology advances.
- Examine the robustness and technological maturity of the capital equipment projected to be used in fabrication of automotive fuel cell power systems, so as to determine where further research and development is required.
- Determine the optimal operating pressure, air stoichiometry and catalyst loading to achieve minimal system cost.
- Thoroughly examine both currently used and developing quality control (QC) measures for each step of the stack manufacturing process to assess cost impact and high rate production feasibility.
- Explore the trade-off between system efficiency and fuel cost in order to optimize the system for lifecycle cost (LCC).

Technical Barriers

This project addresses the following technical barriers from the Fuel Cells section (3.4.4) of the Fuel Cell Technologies Program Multi-Year Research, Development and Demonstration Plan:

- (B) Cost

Technical Targets

This project will provide realistic, defensible fuel cell power systems cost estimates for comparison with the DOE technical targets. Insights gained from these estimates will help to adjust and further validate the DOE targets. Furthermore, our analysis will shed light on the areas in need of the most improvement and thereby provide guidance for future fuel cell research and development efforts.

TABLE 1. DOE Targets/DTI Estimates in \$/kW_{e (net)} (at 500,000 Systems/Year Manufacturing Rate)

	DOE 2010 Target	DTI 2010 Estimate	DTI 2011 Interim Estimate
Stack Cost	\$25	\$25	\$22
System Cost	\$45	\$51	\$48

Accomplishments

- Document 2010 Cost of Automotive Fuel Cell Systems:
 - Prepared a reference report on the cost of automotive fuel cell systems utilizing 2010 technology.
- Assessment of Capital Equipment and Research and Development (R&D) Needs:
 - Tabulated the major capital equipment needed for the manufacturing of all stack and most major balance-of-plant (BOP) components.
 - Evaluated each process and rated them for both cost assumption risk and process risk.
 - Used this ranking system to identify which components are in need of the most R&D in order to achieve risk reduction.
- Optimization of Operating Conditions to Minimize System Cost:
 - Collaborated with Rajesh Ahluwalia at Argonne National Laboratory (ANL) to develop a simplified five-variable stack polarization curve based on ANL's existing models and 2009 polarization data from 3M.
 - Used this simplified polarization curve to independently vary pressure, catalyst loading, temperature and air stoichiometry to select the

optimal combination of parameters for lowest overall system cost.

- Assessment of Fuel Cell Manufacturing QC Systems:
 - Investigated potential QC systems for each step of the stack production.
 - Determined the optimal QC systems to be used both in the 2010 system and 2015 system.
 - Added the appropriate costs and changed the appropriate process parameters for each QC system.
- LCC Assessment of Automotive Fuel Cell Systems:
 - Collaborated with Rajesh Ahluwalia of ANL to conduct basic LCC analysis to determine the optimal tradeoff between system efficiency and fuel cost.
- Preliminary 2011 Cost Assessment:
 - Integrated the above studies with the 2010 cost estimate to prepare a preliminary 2011 automotive fuel cell system cost assessment.
 - Improved existing conceptual design and component specification of complete fuel cell power systems at two technology levels (2011, and 2015).

Introduction

The project seeks to estimate the material and manufacturing costs of complete 80 kW_{net} direct-hydrogen proton exchange membrane (PEM) fuel cell systems suitable for powering light-duty automobiles. The project examines five annual production rates (1,000, 30,000, 80,000, 130,000, and 500,000 systems per year) and three projected technology levels (2010, 2011, and 2015). The project builds upon work previously conducted by DTI for the DOE under a multi-year effort entitled “Mass-Production Cost Estimation for Automotive Fuel Cell Systems”, which focused on annual updates of system cost. Unlike that past effort, the current project is structured as a series of analytic studies, which when taken together, work to strengthen and update the cost analysis to reflect 2011 technology.

Approach

The project consists of a series of semi-independent analyses based on the cost estimation work previously conducted by DTI for 2010 technology automotive fuel cell systems. The approach to each task will be described individually below.

Documentation of the 2010 Cost Estimates: A comprehensive written report was prepared to document the system configuration, designs dimensions, manufacturing and assembly assumptions, and cost results made for the 2010 cost estimates.

Capital Equipment and R&D Needs: Each manufacturing process associated with the stack and some

of the BOP components was evaluated both for the cost assumption risk and process risk. Cost assumption risk gauges risk that uncertainty or errors in assumed capital cost or material cost used in the analysis may lead to significant increases in overall system cost. Process risk gauges the risk that uncertainty or errors in defining the manufacturing and assembly process (including process parameters such as cycle times) may lead to an end product that doesn't meet minimum performance standards or otherwise forces system changes that lead to system cost increase. Both risk scales range from 1 to 3. When these ratings are summed, they yield a combined score which may be used to rank the overall risk of that process or component. Components with a combined score of 4 or more are components that warrant R&D attention.

Operating Condition Optimization: In order to represent stack polarization performance within the cost model, ANL exercised their stack performance model over a range of expected operating conditions to create a numerical database of projected polarization curves. A regression analysis was then conducted on the approximately 600 data points to derive a simplified second-order polynomial equation representing 3M's 2009 current density as a function of five independent variables: cell voltage, catalyst loading, pressure, temperature, and air stoichiometry. This enabled the fuel cell cost model to determine system cost for all combination of these variables. Pressure was varied from 1.5 atm to 3 atm. Air stoichiometry was varied from 1.5 to 2.5. Temperature was varied from 75°C to 95°C. Cathode catalyst loading was varied from 0.10 mgPt/cm² to 0.20 mgPt/cm². (Anode catalyst loading was held constant at 0.05 mgPt/cm².) In addition to the manual optimization, a Monte Carlo analysis was conducted using the @Risk plug-in for Excel. Ten thousand iterations of the DTI fuel cell system cost model were run varying the four stack parameters over the ranges previously states. (Cell voltage was held constant at 0.676 V.) The results were then sorted by resulting system cost. The iteration with the lowest system cost was used to identify the optimal stack parameters.

QC: In order to ensure that adequate QC systems were included in the automotive fuel cell system cost estimates, a comprehensive reassessment of stack manufacturing and assembly QC systems was conducted. The reassessment began with the QC systems utilized in the 2010 system cost estimates and combined it with the PEM-focused QC work being conducted at Ballard, BASF, NREL, the National Institute of Standards and Technology, and Precitec Inc.. Competing QC systems from these organizations were conceptually applied to each step of the stack manufacturing process. The systems were extrapolated to high production rates and assessed on the basis of practicality and cost. In some cases, more advanced QC processes, still in the testing phase, were hypothesized for the 2015 system.

LCC: A simplified LCC analysis was conducted to explore the tradeoff between the initial purchase price of the fuel cell power system and the fuel cost over the lifetime of

the vehicle. By assessing this tradeoff, the system efficiency and operating conditions that lead to the lowest overall lifecycle cost may be identified. The methodology employed consists of three main steps: 1) determination of the stack operating parameters (total catalyst loading, temperature, pressure, air stoichiometry) that lead to minimum system cost at stack efficiencies from 48.8% to 57% (which corresponds to cell voltages of 0.6 to 0.7 volts per cell), 2) determine the relationship between system efficiency and vehicle fuel consumption (miles per gallon gasoline equivalent) for a specified set of vehicle assumptions (vehicle mass, frontal area, rolling resistance, drive cycle, etc.) through use of the ANL PSAT model, 3) determine lifecycle system costs by assessing the net present value of vehicle initial cost and annual operating expenses.

Results

- Results for the capital cost tabulation and risk assessment can be found in Table 2. The highest combined risk scores were for the membrane production process and the nano-structured thin filament (NSTF) catalyst coating process with risk scores of 5.5 and 6, respectively. (NSTF risk is high primarily due to lack of demonstrated performance using high rate production techniques.) In the BOP, the only component with a combined risk score above 4 is the membrane humidifier with a score of 6 (also due to lack of demonstration using high rate production techniques).
- Table 3 displays the optimized parameters that lead to lowest system cost as determined via DTI's parametric analysis of the parameters and verified by Monte Carlo analysis. A sequence of four different scenarios is shown in Table 3: the pre-optimization values used in the DTI 2010 cost analysis, the previous case but with minor system adjustments to the assumptions, the previous case with the new simplified polarization equation from ANL, and finally the post-optimization values using the ANL polarization equation. The resulting system cost is observed to decrease from $\$51.38/\text{kW}_{\text{net}}$ to $\$47.81/\text{kW}_{\text{net}}$. In order to achieve such a cost reduction, stack temperature was increased to its upper limit of 95°C, air stoichiometry was reduced to its lower limit of 1.5, stack pressure was increased to the upper limit of 3 atm, and total catalyst loading was increased to 0.186 mgPt/cm².
- As shown in Table 4, despite the high capital cost of much of the QC equipment, at the highest production level, the cost impact of the added QC is very low, only $\$0.32/\text{kW}_{\text{net}}$. The addition of these systems, however, seeks six-sigma-level quality of the finished products to protect against malfunctions in the manufacturing that would incur costs far exceeding that of the QC equipment.
- The LCC analysis shown in Figure 1 reveals that there is an optimum/minimal lifecycle cost occurring at roughly 44% system efficiency, which translates to

TABLE 2. Manufacturing Process Risk Assessment

Stack Component Manufacturing			
Step/Component	Process Risk	Cost Assumption Risk	Total Score

0.61 volts/cell. However, the optimization curve is very flat and shows only a minor cost change (~\$70) over the range of system efficiencies examined (43% to 51%). Decreases in fuel cost due to increased efficiency are almost totally offset by the subsequent increase in power plant purchase price. Sensitivity analysis shows the optimization curve to be surprising flat over all expected parameter ranges.

Conclusions and Future Directions

Key conclusions from the past year of the project include:

- Membrane fabrication and NSTF catalyst application are the stack components, and the membrane air

TABLE 3. Key Parameters and Cost Results for Different Sets of Parameters

		Base Case (2010 Status)	Base Case w/ Updates	Base Case w/ Updates & ANL Curve Fit	Optimized Case
Annual Production Rate	systems/year	500,000	500,000	500,000	500,000

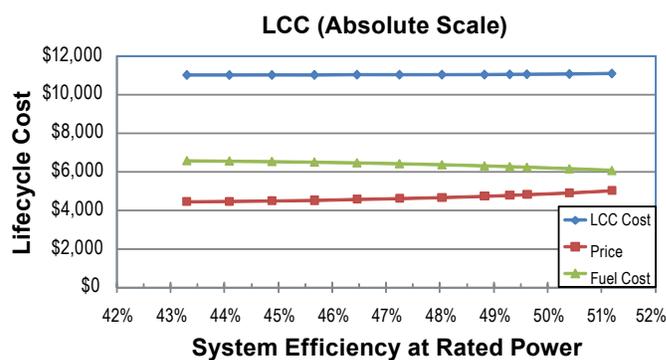

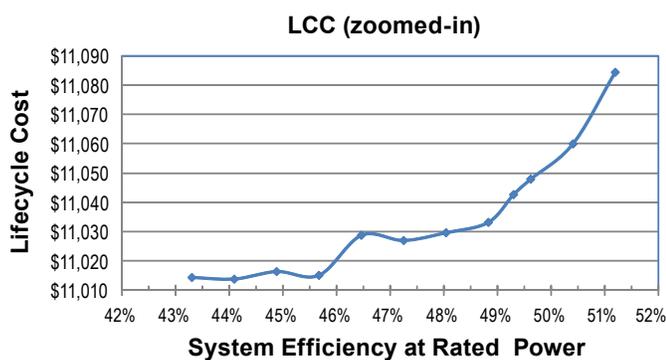

FIGURE 1. Lifecycle Cost Results

humidifier is the BOP component, that carry the highest cost risk. These components have a significant impact on the overall system cost and therefore warrant an R&D focus.

- The system cost is quite sensitive to the oxygen stoichiometric ratio; doubling this value adds roughly \$8/kW_{net} and is a direct consequence of increased compressor size and a larger system gross power.

- Air pressure has a relatively large impact on system cost; the minimum costs at the extremes of the range of validity shift the cost by $\$8/\text{kW}_{\text{net}}$. Above this range, the costs are expected to decrease further and bottom out around 4 atm; although performance at pressures greater than 3 atm are outside the range of validity of the ANL polarization curve fits and thus have greater uncertainty.
- Stack temperature has a limited impact on system cost: the system cost difference between 75°C and 95°C peak temperature operation being only $\$3/\text{kW}$.
- The impact of changing the catalyst loading is comparatively minimal. The maximum cost change between systems optimized across this range of loadings is about $\$2/\text{kW}_{\text{net}}$.
- With the exception of the catalyst loading, all the parameters leading to the minimum system cost are at one of the limits of their ranges of validity. This suggests that these ranges of validity ought to be examined to see if they can be expanded, so as to lower costs further.
- Increases in discount rate minimize net present value of the fuel costs, thus favoring lower efficiency systems that have lower initial capital investments.
- Conversely, increases in H_2 cost increase the lifecycle fuel costs, favoring higher efficiency. Increasing vehicle lifetime favors higher efficiency systems, since longer lifetime increases the relative impact of fuel cost.
- Finally, power system markup increases favor higher efficiency systems that have a lower power system capital cost, and thus a decreased impact due to the higher markup.

Project Start Date: October 1, 2003
Project End Date: Project continuation and
direction determined annually by DOE

- Power density: 650 W/L for system, 2,000 W/L for the stack.
- Specific power: 650 W/kg for system, 2,000 W/kg for the stack.
- Transient response: 1 s from 10% to 90% of rated power.
- Start-up time: 30 s from -20°C and 5 s from $+20^{\circ}\text{C}$ ambient temperature.
- Precious metal content: 0.2 g/kW.

FY 2011 Accomplishments

- Determined the performance of nanostructured thin film catalyst (NSTFC) stacks at low temperatures and on drive cycles.
- Evaluated the dynamic performance of the Honeywell integrated compressor-expander-motor (CEM) module.
- Analyzed the dynamic performance of a parallel ejector-pump hybrid for fuel management.
- Analyzed the dynamic performance of planar and supported liquid membrane humidifiers.
- Analyzed the dynamic performance of microchannel automotive radiators and polymer electrolyte fuel cell (PEFC) stacks during cold start on drive cycles.
- Conducted drive-cycle simulations to determine the fuel economy of hybrid fuel cell vehicles, ownership cost, and optimum fuel cell system (FCS) operating parameters.

Fiscal Year (FY) 2011 Objectives

- Develop a validated model for automotive fuel cell systems, and use it to assess the status of the technology.
- Conduct studies to improve performance and packaging, to reduce cost, and to identify key research and development (R&D) issues.
- Compare and assess alternative configurations and systems for transportation and stationary applications.
- Support DOE/U.S. DRIVE automotive fuel cell development efforts.

Technical Barriers

This project addresses the following technical barriers from the Fuel Cells section of the Fuel Cell Technologies Program Multi-Year Research, Development and Demonstration Plan:

- (B) Cost
- (C) Performance
- (E) System Thermal and Water Management
- (F) Air Management
- (G) Startup and Shutdown Time and Energy/Transient Operation

Technical Targets

This project is conducting system level analyses to address the following DOE 2015 technical targets for automotive fuel cell power systems operating on direct hydrogen:

- Energy efficiency: 50%-60% (55%-65% for the stack) at 100%-25% of rated power.

Introduction

While different developers are addressing improvements in individual components and subsystems in automotive fuel cell propulsion systems (i.e., cells, stacks, balance-of-plant components), we are using modeling and analysis to address issues of thermal and water management, design-point and part-load operation, and component-, system-, and vehicle-level efficiencies and fuel economies. Such analyses are essential for effective system integration.

Approach

Two sets of models are being developed. The GCTool software is a stand-alone code with capabilities for design, off-design, steady-state, transient, and constrained optimization analyses of FCSs. A companion code, GCTool-ENG, has an alternative set of models with a built-in procedure for translation to the MATLAB®/Simulink® platform commonly used in vehicle simulation codes, such as Autonomie.

Results

In FY 2011, we analyzed the dynamic performance of an 80-kW_c net automotive FCS, shown in Figure 1, and its major components (fuel cell stack, and air, fuel, water and thermal management subsystems) on drive cycle transients [1]. The reference FCS is designed to achieve 45% efficiency at rated power (on the lower heating value basis). The stack operates at 75°C and 1.5-atm inlet pressure, the hydrogen and oxygen utilizations are 50%, and the cell voltage is 622 mV. The dew point temperatures at stack inlet are 61°C for cathode air and 53°C for hydrogen after mixing with the recirculated spent anode gas. Here, the stack temperature refers to the coolant exit temperature, the anode and cathode streams flow in opposite directions (counterflow), and the coolant flows in the same direction as the cathode air (coflow) with a 10°C temperature rise across the stack at rated power.

Figure 1 shows the in-line sensors (thermocouples, pressure transducer, differential pressure transducer, voltmeter, ammeter, and shaft revolutions per minute, rpm) used in our model to control and respond to the dynamic loads. The control model is based on a simple hierarchical logic that does not depend on measuring flow rates. The starting step is to determine the resistive load to vary the cell current, using the measured stack voltage as the guide. The

control of the air management system is based on knowing the compressor discharge pressure and the shaft rotating speed (rpm). The model determines the direct current (DC) power to be applied to the motor controller and adjusts the turbine nozzle area as the power demand changes. The fuel management system relies on the measured differential pressure between the cathode and anode inlets to regulate the hydrogen flow rate. The control variable for the water management system is the flow rate of the low-temperature coolant (LTC) to the air pre-cooler using the LTC temperature at the outlet of the traction motor as the measurable temperature. Separate but similar controls are used for the high-temperature coolant (HTC) and LTC circuits of the thermal management system. The control of the HTC circuit depends on the measured HTC temperature at the stack outlet, and the control of the LTC circuit is based on the measured temperature of the LTC at the outlet of the traction motor.

Performance of the Air Management Subsystem

We used experimental data obtained on a full-scale, 100 g.s⁻¹ dry air, unit to model Honeywell’s CEM with a variable nozzle turbine (VNT) [2-4]. The component maps were incorporated into a model for the compressor,

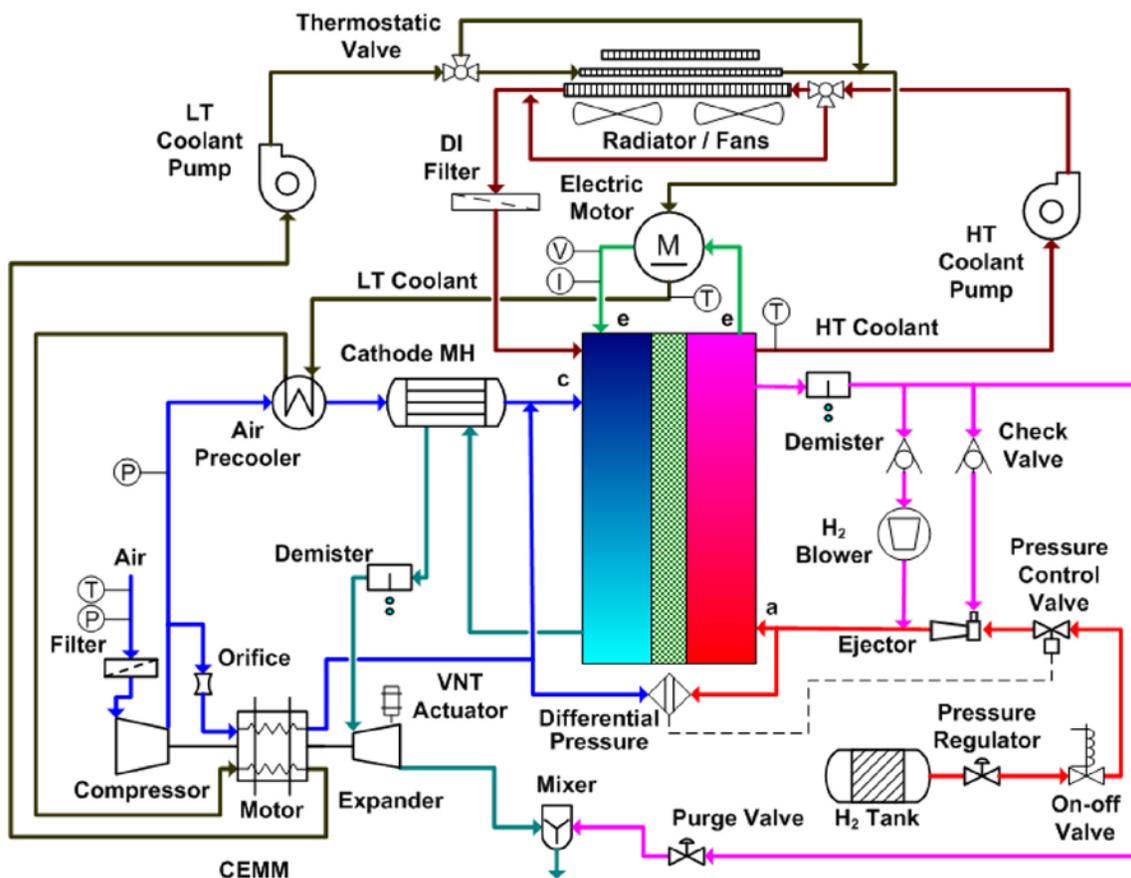

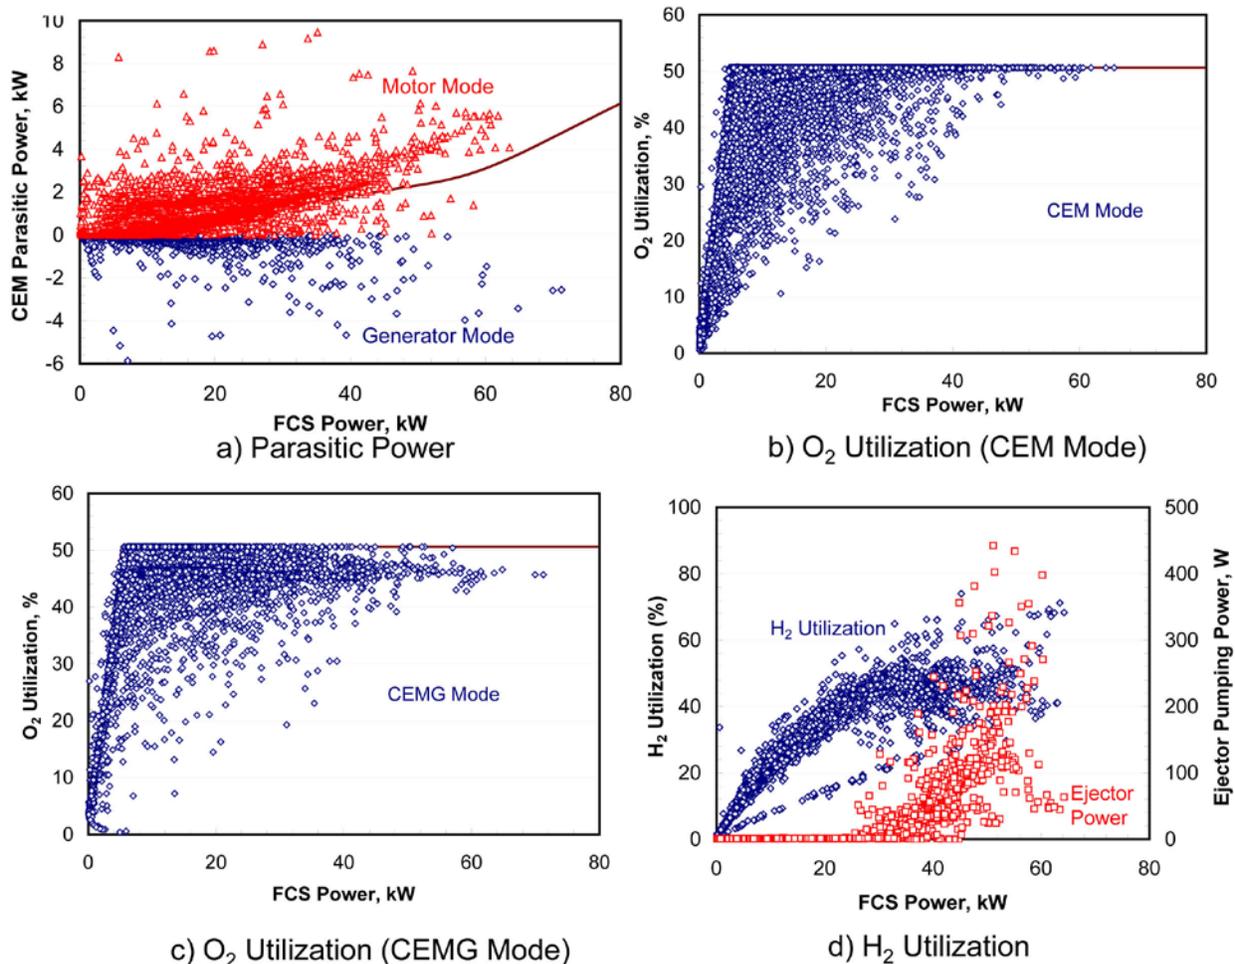

FIGURE 1. Reference FCS with In-line Sensors

expander, and motor that are mounted on a common shaft. The shaft is supported on airfoil bearings, and the motor is powered through a motor controller (DC input). This model was used to analyze the performance of two CEM configurations, one with and one without an expander. The model showed that recovering the compressor bleed air that cools the motor (configuration b with 1-psi pressure drop) reduces the CEM parasitic power by 0.4 to 1.6 kW. Also, an expander reduces the parasitic power by 4 kW if the stack inlet pressure is 2.5 atm (referred to as system S1), and by 1.5 kW if the stack inlet pressure is 1.5 atm (designated as system S2). We found that the CEM turndown (ratio of maximum to minimum flow rate) is a function of the minimum shaft speed (rpm) and may be limited by the compressor surge line. It is desirable to have turndown >10 and a minimum rpm <35,000; otherwise the CEM parasitic power at idle can be >500 W. The minimum shaft speed, if lower than the airfoil bearing lift speed of 36,000 rpm, will affect the durability of the airfoil bearings.

We conducted dynamic simulations to analyze the performance of the CEM (0.25 kg.m² moment of inertia)

on urban (UDDS) and highway (HWFET) drive cycles [3]. We first developed a map for the optimum shaft speed and nozzle area as a function of the air flow rate (FCS power) at steady state; the map also specified the compressor discharge pressure and the CEM parasitic power at part load. We used the map as the reference to determine the target CEM operating conditions for the dynamic simulations. Given a particular power demand, the nozzle area was adjusted to the target value (assuming that the VNT actuator is fast acting), and the DC power to be applied to the motor controller to reach the target rpm in 100 ms was determined. We assumed that the motor in the CEM could be overloaded to 150% of the design value (6 kW for system S2) for short durations.

The symbols in Figure 2a represent the electric power that must be supplied to the CEM on the UDDS and HWFET drive cycles in the S2 system with an expander and configuration (b). These may be compared with the solid line that represents the power consumed by the CEM at steady state. We see that the power consumed by the CEM during an acceleration transient can be substantially greater than

(symbols: dynamic results; solid line: steady-state simulation)

FIGURE 2. Dynamic Performance of the Air and Fuel Management Subsystems

the power required at steady state because of the extra power needed to increase the shaft speed. Conversely, the power consumed by the CEM during a deceleration transient can be less than the power required at steady-state conditions and may even be zero. Similarly, Figure 2b compares the oxygen utilization on the UDDS and HWFET cycles with the steady-state values represented as solid lines for 50% O₂ utilization and a maximum turndown of 20. We see that the cathode stoichiometric ratio (reciprocal of oxygen utilization) is >2 during deceleration and >>5 at low FCS power.

We also conducted simulations to assess the benefits of operating the motor as a compressor expander motor-generator module (CEMG). Figure 2a shows instances where there is net production of power by the CEMG unit during hard deceleration. However, the instances of higher than steady-state CEMG power requirement are also more frequent, since the shaft speed decreases faster during deceleration and must be increased more rapidly during a subsequent acceleration. Figure 2c indicates that the scattered data points are clustered closer to the steady-state O₂ utilization curve because of faster response to the deceleration transients.

Performance of the Fuel Management Subsystem

We developed a model to analyze the performance of a parallel ejector-pump hybrid in the fuel management system [3]. We considered that the motive gas is pure hydrogen from the compressed gas tank and the suction gas is spent hydrogen from the stack outlet. We assumed that the motive gas is available at a pressure no less than 22 bar (regarded as the empty tank pressure) and that the suction gas is saturated with water vapor (molecular weight of 3-7) at 1-1.15 atm (S2 scenario).

Our dynamic control algorithm for the fuel management system consists of a pressure regulator to lower the pressure of motive hydrogen to 22 bar and a pressure control valve to further lower the pressure at the inlet to the ejector. The hydrogen flow rate is varied by changing the pressure at the throat of the ejector in order to have zero differential pressure across the cathode and anode channels. The maximum hydrogen flow rate is set to 150% of the value at rated power.

Figure 2d summarizes the results from the dynamic simulation of the fuel management system with a single-speed, 40-W blower that is always kept on. The H₂ utilization on the UDDS and HWFET cycles is maintained at about 50% for >30% of the rated FCS power, but it is much less than 50% near idling conditions. With hydrogen feed rate being proportional to the pressure differential between anode and cathode inlets, H₂ utilization can be >60% during rapid deceleration that depressurizes the anode gas channels. Figure 2d also includes the calculated ejector pumping power defined as the flow rate of the entrained gas times the pressure head. We see that the pumping power can approach 400 W, which is equivalent to a 1-kWe reduction in parasitic

power (i.e., power that a 40%-efficient blower would need to provide if the system did not include an ejector).

We ran simulations in which the feed hydrogen contains inert impurities at levels of 100-ppm N₂ and 200-ppm He [5]. The simulations include crossover of N₂ from cathode to anode and the crossover of He from anode to cathode. We determined the dynamic buildup of the inerts assuming that 15 standard liters of anode gas (equivalent to 2 times the volume of the anode circuit) are purged by supplying H₂ at the maximum flow rate (150% of the H₂ flow rate at rated power) when the inerts build up to 10 mol%. Our simulations indicate that the purge schedule is largely determined by the crossover of N₂ from cathode air rather than the level of impurities in feed hydrogen.

We determined the purge loss and the interval between purges for constant FCS power and on UDDS and HWFET drive cycles. We found that H₂ purge loss increases as the FCS power decreases; it can exceed 10% of the feed near idling conditions. Also, the purge schedule and loss are proportional to the allowable N₂ concentration in the anode channels. Thus, the interval between purges will be nearly twice as long, and the purge loss will be nearly half as much, if the allowable N₂ concentration is increased from 10% to 20%.

Performance of the Water Management Subsystem

For the membrane humidifier for the cathode inlet air, we developed a transient model to determine the heat and mass transfer between the counterflowing wet and dry streams that are separated by a perfluorosulfonic acid (PFSA) membrane [6]. The model considers water uptake from the wet stream, diffusion through the PFSA membrane, and desorption into the dry stream. The model was validated against experimental data from a full-scale (appropriate for an 80-kW_e automotive FCS), a half-scale, and a sub-scale (1/10th) unit assembled as a bundle of Nafion® tubes arranged like a shell and tube heat exchanger [6].

We used the model to analyze the performance of a planar humidifier (20- μ m-thick membrane, 3 m² active area) sized to raise the dew point temperature of cathode air (S2 configuration) to 61°C by transferring moisture from the spent saturated air leaving the stack at 75°C. The dry air temperature is lowered from 120°C at compressor discharge to 65°C in a pre-cooler.

Figure 3a shows the modeled performance of the humidifier on UDDS and HWFET cycles. The results are shown as a scatter plot of cathode air relative humidity (RH) calculated at the stack (bipolar plate) inlet temperature (nominally 65°C). The triangle symbols designate the results for the initial startup time when the stack and other components are still warming up. The square symbols represent results after the coolant temperature at stack inlet reaches 65°C. A >100% RH in Figure 3a implies that the cathode air is leaving the humidifier at a temperature higher than the bipolar plate temperature at stack inlet. Both

steady-state and dynamic simulations follow the general trend that the RH first increases as the air flow rate (FCS power) is reduced, reaches a peak, and then decreases as the CEM reaches the turndown limit. In the turndown limit, the cathode stoichiometry increases as the FCS power is reduced (see Figure 3a) and at certain points, the RH of air at the stack outlet may drop well below 100%.

Performance of the Thermal Management Subsystem

We analyzed the performance of a cross-flow automotive radiator with 40 plain microchannel fins per inch (0.4 m² frontal area, 2.3 m² fin area, 500 W blower fan) and evaluated its ability to reject the waste heat from an 80-kW_e S2 system [3,7]. We concluded that the fuel cell powertrains might need to be derated for ambient temperatures higher than 40°C since the fan power doubles for every 5°C increase in ambient temperature. We assessed the prospect of allowing stack temperatures to rise to 95°C under transient conditions (e.g., hill climbing at 55 mph) where high heat rejection may be required for several minutes. We determined that the maximum stack temperature is limited by the system pressure and the dew-point temperature of the cathode air at stack inlet. Also, under these conditions of high load, the CEM motor power may limit the ability to pressurize the cathode air adequately if the CEM does not include an expander.

We ran dynamic simulations of the heat rejection system on UDDS and HWFET cycles using a dynamic control strategy that operates at three levels. First, the flow rate of the stack coolant is varied linearly with the FCS power. Second, the thermostatic valve is completely open so that the coolant bypasses the HTC radiator if the stack outlet temperature is below a minimum set point (70°C). The valve is completely closed to allow all the coolant to flow through the radiator if the coolant temperature is above the design point (75°C). The bypass fraction is linearly varied between 0 and 1 if the coolant temperature is between the two set points. Third, the radiator fan is operated in on-off mode, i.e., the single-speed fan operates only if the coolant temperature at stack inlet exceeds 65°C.

Our results indicate that it takes about 500 s for the polymer electrolyte membrane fuel cell (PEMFC) stack and the stack coolant to reach their design temperatures on the UDDS cycle with cold start from 300 K. After this time, the coolant temperature fluctuates due to variations in vehicle speed (i.e., flow rate of ram air), stack heat load, continuous adjustment of the thermostatic valve, and the blower fan turning on and off.

Stack and System Performance

A two-dimensional model [3] was adapted to analyze the performance of a stack with NSTFC-based membrane-electrode assemblies. The NSTFC-specific constants for the model were derived from experimental data with 25-cm² active area cells [8].

Figure 4a presents the polarization curves constructed from the results for cold-start simulation on UDDS and HWFET cycles and for steady-state operation (system S2). The operating pressures in these simulations varied with current density (air flow rates) as determined by the CEM module. The scatter in cell voltage for the same current density is due to variations in stack temperature over time, cathode stoichiometry (higher during deceleration), and cathode inlet pressure (function of flow rate and shaft rpm). We have identified the coolant exit temperatures for some of the data points in Figure 4a to indicate the dominating effect of stack temperature on the polarization curves. The results indicated that flooding limits the stack power to ~32 kW_e at 30°C and ~50 kW_e at 45°C.

Figure 3b presents the relative humidity of the anode stream at the inlet to the stack. Since there is no humidifier in the anode circuit, and the feed H₂ is dry, the

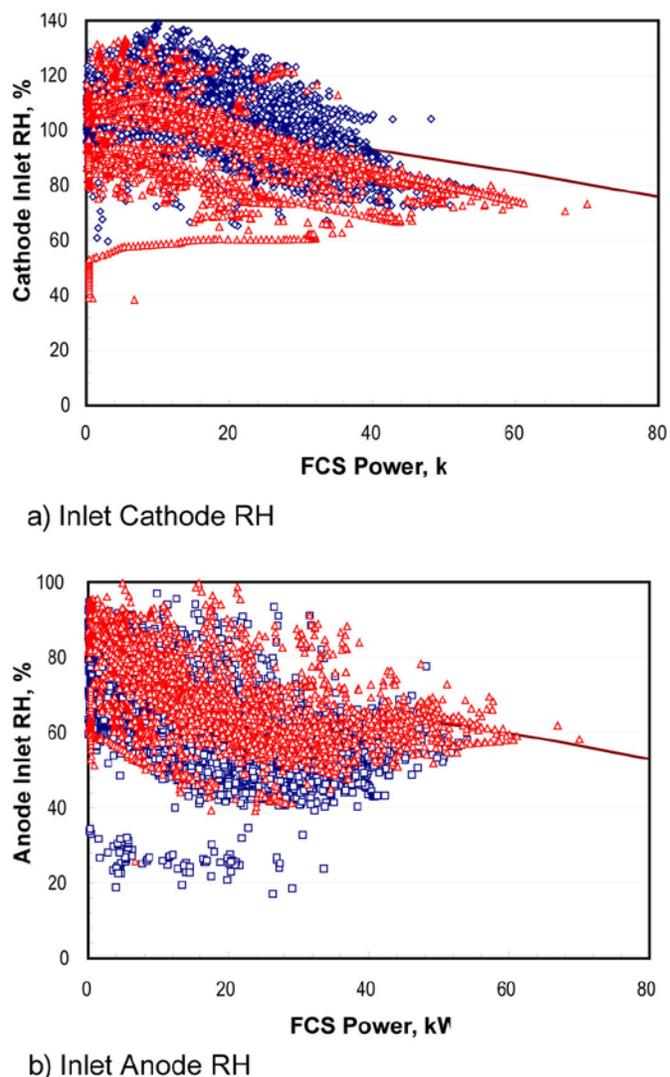

FIGURE 3. Dynamic Performance of the Water Management Subsystem

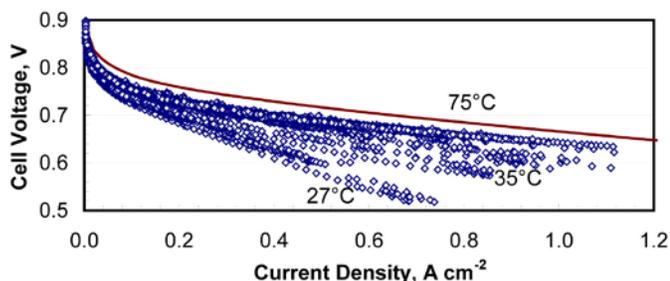

humidification of the anode stream is entirely due to water transport from the cathode through the membrane and recycle of the spent anode gas. As in Figure 3a, the triangle symbols designate the results for the initial startup time when the stack and other components are still warming up, and the square symbols represent results after the coolant temperature at stack inlet reaches 65°C. The isolated points with very low humidities represent instances of time that the anode is purged to relieve N₂ buildup and the accompanying loss of moisture with the purge gas.

Finally, Figures 4b and 4c summarize the instantaneous FCS efficiency on the UDDS and HWFET drive cycles. We see a larger spread in the efficiencies if the CEM motor is operated as motor/generator. The sporadic high efficiency points in the CEM generator (CEMG) mode are due to power generated by the air management system during rapid deceleration. These are generally followed by sporadic low

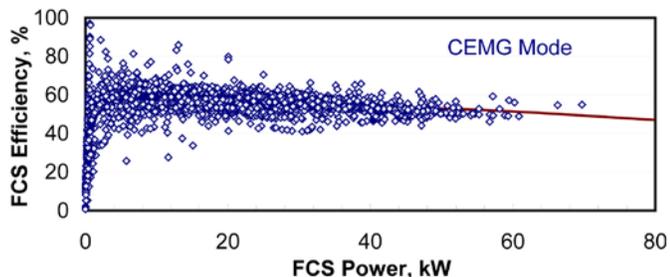

efficiency points because of the parasitic power consumed in spinning-up of the CEMG shaft to higher speeds.

Conclusions and Future Directions

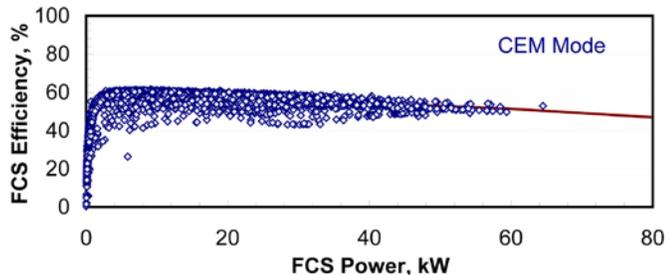

- System performance and stack polarization curves can deviate significantly from the steady-state values, especially during startup from 300 K. The transient FCS efficiency can be much higher than the peak steady-state efficiency during deceleration, or much lower during acceleration and while the stack is below its normal operating temperature of 75°C.
- Operating the CEM motor as motor/generator improves the CEM response during deceleration, although the transient cathode stoichiometry can still be >2 (design point stoichiometry ratio) at low loads and >>2 in the CEM's turndown limit.
- A hybrid blower-ejector arrangement controlled by a differential pressure sensor can maintain H₂ utilization at 50% or lower on the UDDS and HWFET drive cycles. A periodic purge is needed to control the buildup of N₂ in the anode recycle loop due to crossover from cathode air.
- At low loads, the RH can exceed 100% at cathode inlet (60% at design rated power) and reach 80-90% at the anode inlet (50% at design rated power), even without an external anode humidifier.
- In FY 2012, we will investigate the effects of alternative system configurations, rated power efficiency (Pt content) and system operating points on the high-volume manufacturing cost, dynamic drive-cycle performance, and component durability.

Project Start Date: Fiscal Year (FY) 1999
Project End Date: Project continuation and
direction determined annually by DOE

FY 2011 Objectives

- Develop new, innovative microanalysis and imaging techniques to characterize fuel cell material constituents before, during, and after electrochemical aging.
- Elucidate membrane electrode assembly (MEA) degradation and/or failure mechanisms by conducting extensive microstructural characterization using advanced electron microscopy techniques. In particular, distinguish individual materials degradation phenomena as a function of aging protocol, including catalysts, supports, ionomer, membrane, microporous layer (MPL), and gas diffusion layer (GDL).
- Develop the critical correlations between MEA microstructure, composition, and architecture, and MEA durability.
- Compare microstructural changes resulting from accelerated stress testing (AST) with microstructures observed after field aging to determine efficacy of ASTs.
- Collaborate with fuel cell component developers and manufacturers, university researchers, and other national laboratories, to evaluate fuel cell material components using electron microscopy and complimentary microstructural and compositional microanalysis techniques.

Technical Barriers

This project addresses the following technical barriers from the Fuel Cells section (3.4.4) of the Fuel Cell Technologies Program Multi-Year Research, Development, and Demonstration Plan:

- (A) Durability
- (B) Cost
- (C) Performance

Technical Targets

Insights gained through extensive microstructure characterization of MEA constituents will be applied toward the design and manufacture of fuel cell materials that meet the following DOE 2015 MEA targets:

- Cost: <\$5/kW
- Durability with cycling: 5,000 hours
- Operating temperatures: <120°C
- Total catalyst loading (for both electrodes): 0.2 g/kW (rated)
- Extent of performance degradation over lifetime: 5%

FY 2011 Accomplishments

- Used a combination of analysis techniques and MEA samples to characterize the nature of the recast ionomer (films, pockets, etc.) within electrode structures and to understand the nm-scale phase-separated morphology consistently observed in Nafion® membranes.
- Directly compared degradation phenomena observed in “real world” field-aged proton exchange membrane fuel cell (PEMFC) MEAs with MEAs aged via AST protocols designed to enhance specific degradation mechanisms (e.g., carbon corrosion, catalyst coarsening, etc.).
- Established collaboration with Nissan to evaluate catalysts (in terms of structure, size, and morphology) deposited on a series of carbon supports exhibiting varying degrees of graphitization.
- Initiated fundamental study of Pt deposition on model carbon substrates (graphene) to understand Pt nucleation and growth mechanisms on extended graphitic surfaces.
- Established a new collaboration with General Motors to characterize a complete series of PEM fuel cell MEAs aged to accelerate membrane degradation.
- Optimized analysis parameters for the compositional analysis of catalyst nanoparticles via aberration-corrected scanning transmission electron microscopy (STEM), including elemental mapping.
- Host an international collaborator from Fuel Cell Cubic (FCC), Tokyo, Japan, to characterize new materials for PEM fuel cells. The FCC researcher will work at ORNL for the next year.

Introduction

PEMFCs are being developed for future use as efficient, zero-emission power sources. The performance of PEMFCs degrades during electrochemical aging, and this performance

degradation can be correlated directly with the durability of individual components comprising the MEA, e.g., the electrocatalyst, catalyst support, ionomer, and/or the proton-conducting polymer membrane. Many of the material's microstructural and compositional attributes that contribute to decreased stability of the MEA during long-term electrochemical aging are not yet fully understood and have not directly been correlated with performance as a function of aging protocols. In order to reach DOE's technical targets for MEAs, correlating the individual component materials structure, composition, and interrelationships within the MEA layers with the measured performance as a function of different aging conditions, is critical for applying materials optimization practices to increase fuel cell materials durability for specific applications.

During the course of this project, the Microstructural Characterization Program at ORNL has been focused on forming collaborative relationships with a wide range of industrial PEMFC developers/manufacturers, university researchers, and national laboratories, to utilize advanced microscopy techniques as a means to evaluate as-fabricated and electrochemically aged PEMFC MEAs and, most importantly, to characterize individual PEMFC material components and relate structural and chemical changes of these materials to the performance degradation resulting from particular aging conditions. These studies are used to establish the critical processing-microstructure-performance relationships that can then be reported to the MEA producers (and in many circumstances, the fuel cell community as a whole), which can result in improved stability of the MEA materials, thereby enhancing MEA performance and lifetimes. Understanding the structural and compositional changes to the materials comprising the MEA during electrochemical aging will allow for the implementation of processing changes and critical materials development that are required for optimized PEMFC durability and performance. The techniques developed as part of this "baseline" research project are being applied to other fuel cell systems.

Approach

The microstructural characterization task utilizes advanced electron microscopy analysis techniques to characterize the individual material components comprising PEMFCs, before and after incorporation into an MEA and after electrochemical aging. Our approach is focused on identifying and optimizing novel high-resolution imaging and compositional/chemical analysis techniques, and developing unique specimen preparation methodologies, for the μm - \AA -scale characterization of the material constituents of fuel cells (electrocatalyst, catalyst support, ionomer, membrane, etc.). ORNL applies these advanced analytical and imaging techniques for the evaluation of the microstructural and microchemical changes of each material constituent and correlating these observations with fuel cell performance (aging studies are conducted

at the collaborator's laboratories). These studies are designed to elucidate the microstructure-related degradation mechanisms contributing to fuel cell performance loss. Most importantly, ORNL is making the techniques and expertise available to fuel cell researchers outside of ORNL via several mechanisms – (1) work for others (proprietary) research, (2) ORNL User Facilities (e.g., Shared Research Equipment User Facility, Center for Nanophase Materials Science), and (3) collaborative non-proprietary research projects via the Microstructural Characterization Project that are in line with ORNL's "baseline" research activities.

Results

Ionomer Characterization

High-resolution microscopy characterization of the recast ionomer "film" distributed within the electrodes of a PEMFC poses numerous challenges, the most critical being the inhomogeneous and non-continuous nature of the ionomer. Typically, the ionomer film is not a uniform-thickness film surrounding the Pt catalysts on carbon black (Pt/CB) supports, but tends to exist in pockets/clumps in localized regions between Pt/CB particles or agglomerates, which have a high number density of Pt nanoparticles. Isolating ionomer regions for high spatial resolution chemical/compositional analysis or imaging is extremely difficult. To study the ionomer phase within an electrode, it was necessary to prepare electrodes with greater amounts of ionomer to create isolated "ionomer-only" regions. Thus, rather than characterizing electrodes with 28-30 wt% ionomer, the samples used for this work contained ~61 wt% ionomer, which resulted in dense electrodes having filled porosity, as shown in Figure 1 where a large pore between Pt/CB regions is completely filled with ionomer. The large ionomer-filled-pore regions (generally $>50\ \mu\text{m}$) were sufficiently large for microanalysis via electron energy loss spectroscopy (EELS) in the transmission electron microscope (TEM)/STEM, and a bulk electrode content high enough for comparing with X-ray photoelectron spectroscopy (XPS) characterization. In addition, these dense electrodes were prepared for TEM/STEM by cryo-microtomy using no epoxy embedding (ensuring that the only polymer present in the sample was the ionomer).

The XPS results acquired from the electrode containing ~61 wt% were also compared with XPS data for a Nafion[®] 212 membrane. It is important to note that the XPS data were acquired from an electrode that was "chopped up" such that the ionomer inside the electrode (filling pores) was analyzed rather than any ionomer skins present on the bulk electrode surfaces. The primary conclusions from the bulk XPS analyses were (1) the Nafion[®] 212 membrane exhibited more CF_2 -type (PTFE) bonding (the ionomer was depleted in fluorine ($\text{CF}_2/\text{CF}_3=3.8$) compared to the membrane ($\text{CF}_2/\text{CF}_3=5.0$)) and (2) the $-\text{SO}_3$ (sulfonate) peak shifts to a lower binding energy for the 61 wt% ionomer sample, which is consistent with the sulfonate groups no longer being

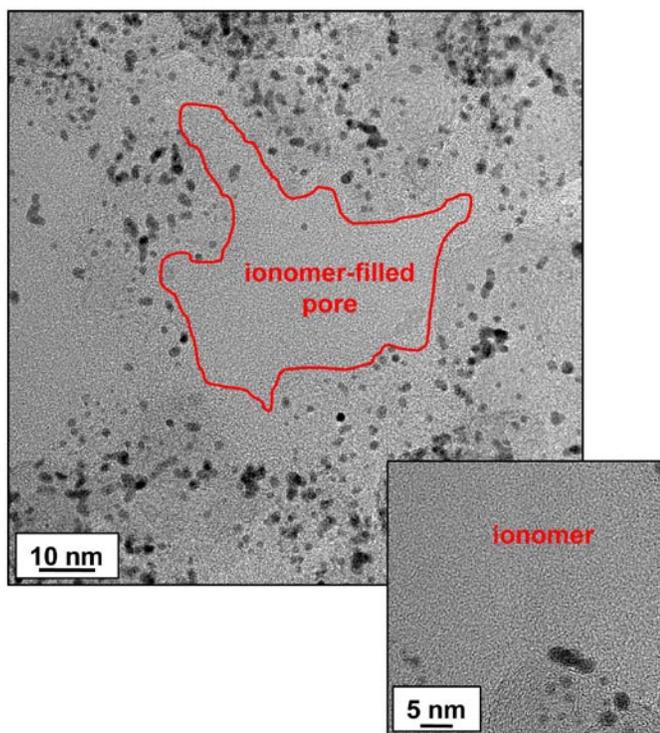

FIGURE 1. To isolate ionomer regions for TEM/STEM/EELS analysis, electrodes were prepared such that the pores were filled with ionomer (61 wt% ionomer mixed with Pt/C decal-electrodes).

influenced by or associated with the $-CF_2$ backbone, i.e., these groups have been removed from the $-CF_2$ backbone or the sulfonate groups are located in a sub-surface position. EELS spectrum images (SI) were acquired in the STEM within the individual ionomer-filled pores surrounded by Pt/CB particles. A typical ionomer pocket used for EELS-SI is shown in the STEM image in Figure 2 together with the derived carbon and sulfur EELS maps. Phase

separation within the ionomer is clear – the sulfur (and oxygen – not shown) is associated with the Pt/CB region, whereas the carbon (and fluorine, not shown) is uniformly present within the ionomer filling the pore. Additionally, energy dispersive spectroscopy (EDS) analysis of an MEA (prepared with a “standard” ionomer content of 28 wt%) consistently shows higher sulfur associated with Pt/CB regions. These data are consistent with the XPS data from the ionomer that shows clear “localization or separation” of the sulfonate groups away from the Teflon[®]-backbone of the Nafion[®] and the existence of the sulfonates in a sub-surface position. Separation of the hydrophilic sulfonate groups will have the greatest impact on the confinement of water and water uptake within the electrode. In a recent article by Kim and Pivovar [1], PFSA membranes are described as “highly phase-contrasted polymers” due to the extreme hydrophobicity of the CF_2 -backbone and mobility of the SO_3^- -group – phase contrast refers to the extent of separation between the hydrophilic and hydrophobic regions. The ionomer within the electrodes appears to be more phase-contrasted than the membrane and according to [1], this should have the greatest impact on water uptake.

Initiation of Pt Nucleation and Growth Studies Using “Model” Carbon Surfaces

For fuel cell applications, electrocatalysts are currently supported on a variety of carbon black (CB) supports, each exhibiting different degrees of graphitization. These include Ketjen black and Vulcan (high surface area supports) and their heat-treated counterparts, where heat treatments are employed to enhance the graphitic nature of the CB. The high surface area CB support structures are typically textured turbostratic carbon with a particle (domain) size of ~4-5 nm, where the rounded surfaces of the supports are comprised of highly aligned domains that each terminate predominantly with hexagonal carbon (002) planes on the surface. This “mosaic structure” is shown in Figure 3a,

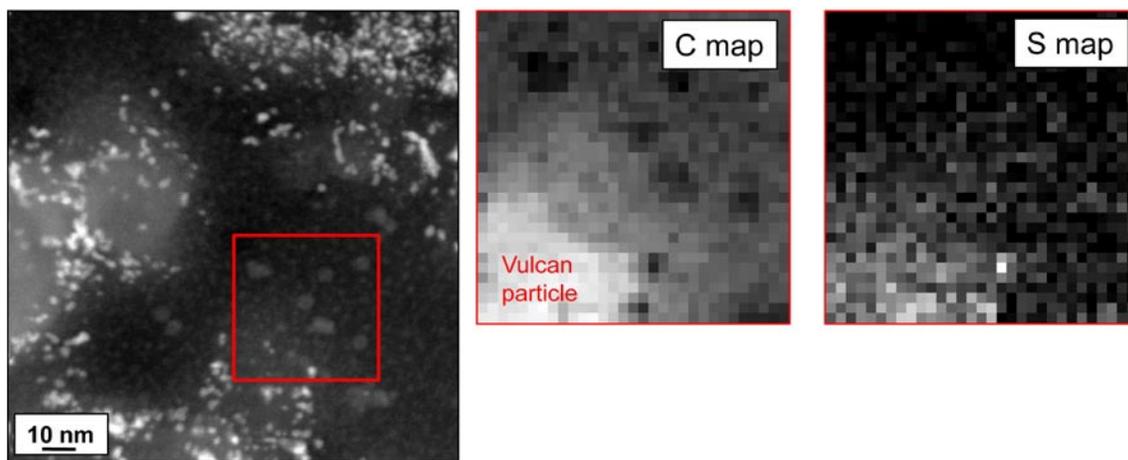

FIGURE 2. EELS spectrum imaging data from 61 wt% ionomer sample. Sulfur was consistently associated with Vulcan Pt/CB regions within the electrode structure.

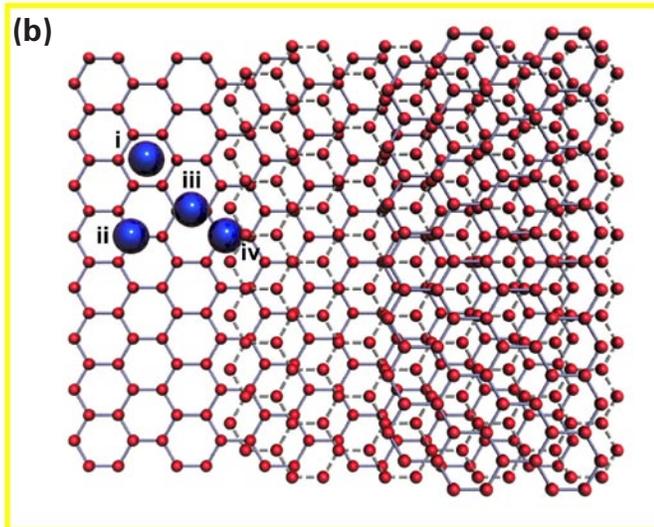

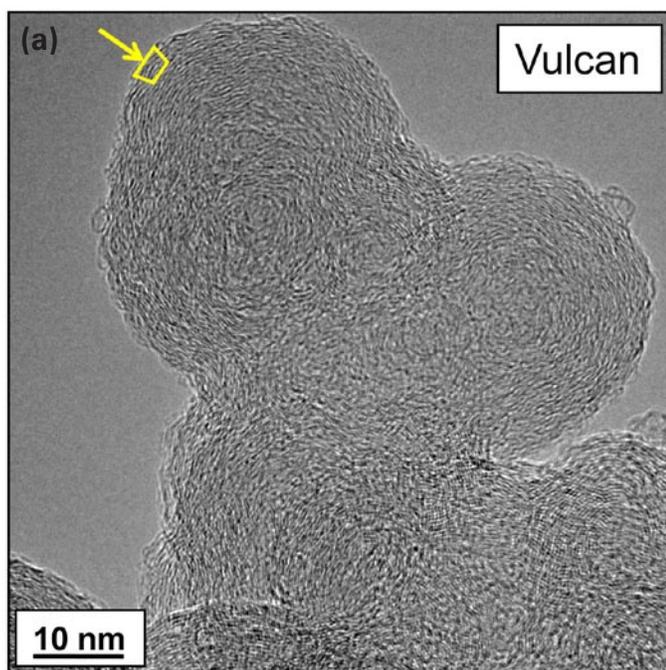

FIGURE 3. (a) Vulcan particle with overlay of typical carbon crystalline domain (yellow). (b) Schematic of (002) graphene surface showing possible Pt atom deposition sites (i) center of 6-atom carbon ring, (ii) top of single carbon atom, (iii) “bridge” site between two carbon atoms, and (iv) step/edge between graphene layers.

where a typical domain is shown by the yellow outline on the TEM image of a Vulcan CB particle. The (002) domain surfaces can be modeled using graphene films, since all nanostructured carbons have “graphene-based” structures, i.e., layered sheets of graphene comprise highly ordered graphite. In this way, sp^2 -bonded graphene sheets/films (single- or multi-layered) are being used (in place of CB spheres that are difficult to characterize by TEM/STEM) to identify preferred Pt deposition sites on CB surfaces and to study Pt nucleation and growth mechanisms. These

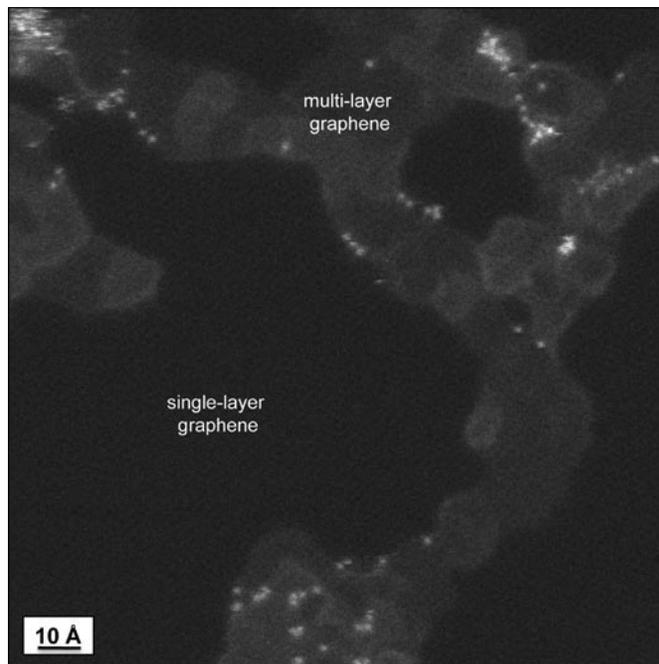

FIGURE 4. Z-contrast STEM image showing the different layers of graphene and individual Pt adatoms (brightly imaging) deposited on surface. Note that all Pt atoms deposit at edge sites and not on sites associated with the sp^2 -bonded (002) surfaces.

studies will also be used to identify more stable sites for Pt deposition that can enhance catalyst stability.

Several critical steps have been taken to initiate this fundamental Pt nucleation and growth study in FY 2011. We have identified a source of continuous, multi-layered graphene films supported on the 3 mm Cu grids necessary for the TEM/STEM experiments (source - the Graphene Supermarket). These films are relatively pure/clean and exhibit large areas of single-layer graphene as well as defects – steps/edges, vacancies, etc. – at the regions where graphene sheets overlap. We have also successfully deposited very low levels of Pt (<3 wt%) directly on the 3 mm graphene-coated Cu grids using a $[Pt(NO_3)_2 \cdot (NH_3)_4]$ Pt precursor, such that individual Pt atoms as well as small Pt clusters are deposited, which is the desired loading and dispersion. In this way, we can identify the preferred site for Pt deposition and in the future, the most stable site. Possible sites available on the graphene films for Pt deposition are illustrated in Figure 3b and include (i) the center of the 6-atom carbon ring, (ii) on top of a carbon atom, (iii) the “bridge” site between two carbon atoms, and (iv) the step/edge at the sheets layers. Figure 4 shows a preliminary Z-contrast STEM image of individual Pt atoms (bright spots) distributed on graphene sheets. This preliminary data indicates that Pt atoms prefer to deposit at the edge sites where layers of graphene overlap (from single-layer to double-layer, or double-layer to triple-layer, etc.), and in fact, these are the only sites where Pt atoms were identified on the film surface. This is initial experimental

evidence showing that Pt atoms do not deposit on, nor do clusters nucleate on, the sp^2 -bonded surfaces of graphite, but preferentially locate on defects. Additional research is planned to fully explore the adsorption, nucleation, and growth of Pt on carbon (002) surfaces such that carbon structures can be optimized to stabilize Pt electrocatalysts for use in fuel cells, including theoretical modeling (density functional theory calculations), Pt loading studies, introduction of defects in the carbon structure, and heating experiments.

Conclusions and Future Directions

- Complete Pt nucleation and growth study using “model” graphene surfaces, including density functional theory calculations for comparison with experimental results, and in situ heating experiments.
- Correlate microstructural/compositional observations with AST protocols (automotive and stationary), especially related to catalyst coarsening and migration, carbon corrosion, membrane degradation – this is a continuing priority of this research project and has been part of ongoing and proposed “future” research each year.
- Acquire the proper series of durability-tested MEAs to further understand the degradation of polymer electrolytes (membrane and ionomer in electrode) using a combination of characterization techniques – continue ionomer studies initiated in FY 2011.
- Correlate observations of Pt nucleation and growth to long-term stability via in situ liquid electrochemistry experiments.
- Continue to establish collaborations with industries, universities, and national laboratories (including access via ORNL User Facilities) to facilitate “transfer” of unique capabilities.
- Support new DOE projects with microstructural characterization and advanced characterization techniques, which remains the primary focus of this project.

E-mail: Nancy.Garland@ee.doe.gov

Contract Number: DE-AI-01-01EE50660

Project Start Date: Fiscal Year (FY) 2001
Project End Date: Project continuation and
direction determined annually by DOE

- Cost: \$35/kW_e.
- Start-up time to 50% power: 30 seconds from -20°C, 5 seconds from 20°C.
- Freeze start operation: unassisted start from -40°C.
- Durability with cycling: 5,000 hrs.

FY 2011 Accomplishments

- Developed methods to achieve better than 10 μm spatial resolution:
 - Further improvements to the spatial resolution require new approaches; one method has shown a factor of 25 improvement in spatial resolution.
 - Improvements to the design of this method will be pursued to achieve ~1 μm resolution to enable measurement of water distribution within commercial membrane electrode assemblies (MEAs).
- Carried out studies of water transport in full-scale hardware and 4-cell stacks:
 - Hydrophilic coatings on bipolar plates reduce water retention and time to purge the cell during shutdown.
 - Diffusion media saturation is linked to individual cell failure in stacks.
- High resolution imaging of water transport in thick catalyst layers and impact of water on fuel cell durability:
 - Strategies to overcome flooding will help improve the performance of polyaniline-derived non-precious metal catalysts.
 - Corrosion results in an increased overpotential, which dries out the cell under operation at constant current due to a larger thermal gradient.

FY 2011 Objectives

- Provide neutron imaging-based research and testing infrastructure to enable the fuel cell industry to design, test, and optimize prototype to commercial-grade fuel cells.
- Provide a secure facility for proprietary research by industry. Make open research data available for beneficial use by the general fuel cell community.
- Continually improve and develop methods and technology to accommodate rapidly changing industry/academia needs.

Technical Barriers

This project addresses the following technical barriers from the Fuel Cells section (3.4) of the Fuel Cell Technologies Program Multi-Year Research, Development and Demonstration Plan:

- (A) Durability
- (C) Performance
- (D) Water Transport within the Stack

Technical Targets

- Unassisted start from low temperature: -40°C.
- Durability with cycling at operating temperature of ≤80°C: 5,000 h.
- System energy density: 650 W/L.
- System specific power: 650 W/kg.
- Energy efficiency: 65% at 25% rated power, 55% at 100% rated power.

Introduction

At NIST, we maintain the premier fuel cell neutron imaging facility in the world and continually seek to improve its capabilities. This facility provides researchers a powerful and effective tool to visualize and quantify water transport inside operating fuel cells. Imaging the water dynamics of a polymer electrolyte membrane fuel cell (PEMFC) is carried out in real time with the required spatial resolution needed for fuel cells that are being developed today. From these images, with freely available NIST-developed image analysis routines, PEMFC industry personnel and researchers can obtain in situ, non-destructive, quantitative measurements of the water content of an operating PEMFC. Neutron

imaging is the only in situ method for visualizing the water distribution in a “real-world” PEMFC. Unlike X-rays, whose interaction with materials increases with the number density of electrons, neutrons interact via the nuclear force, which varies somewhat randomly across the periodic table, and is isotopically sensitive. For instance, a neutron’s interaction with hydrogen is approximately 100 times greater than that with aluminum, and 10 times greater than that with deuterium. It is this sensitivity to hydrogen (and insensitivity to many other materials) that is exploited in neutron imaging studies of water transport in operating fuel cells.

Approach

The typical length scales of interest in a PEMFC are: channels approximately 1 mm wide and 1 mm deep, the diffusion media (DM) are 0.1 mm to 0.3 mm thick, the membrane is 0.01 mm to 0.02 mm thick, and the active area is 2 cm² to 500 cm². Thus, to nondestructively study in situ the water and hydrogen transport in PEMFCs while in operation we will develop new facilities and improve existing capability for obtaining high spatial and temporal resolution neutron images. Employing the mathematical models of neutron scattering, we will develop a software suite that enables users to obtain quantitative measurements of the water content in an operating PEMFC. Due to the complexity of PEMFCs and the large number of open questions regarding water transport in PEMFCs, we will develop partnerships with industry, academia, and national laboratories to train them in the use of the facility, collaborate with them on research projects, and seek their feedback to pursue future technical breakthroughs.

Results

Visualizing water transport in a fuel cell is a process that occurs on several different length scales. In-plane studies require spatial resolution on the order of 100 μm and this capability has existed from the outset of this project. However, to image water transport in the through-plane of a fuel cell in the DM, membrane, and catalyst layers it has been necessary to improve the image resolution, which currently stands at 10 μm . This resolution is well suited to studies of the DM, but to image the membrane and catalyst layer it is necessary to go well below 10 μm . To do this, new methods must be developed due to fundamental limitations that arise from the physics of neutron capture and detection in the detector that limit the overall resolution to 10 μm . Three

different methods have been considered for achieving image spatial resolution better than 10 μm . The first utilizes a technique derived from neutron depth profiling (NDP), the second uses optical magnifying lenses, and the third a scanning set of slits. The NDP technique can possibly achieve a spatial resolution of 100 nm, but the field of view in one dimension is severely restricted to about 10 μm due to the need for charged particles from the neutron capture reaction to escape and be detected. Due to challenges in the fabrication of the detection volume, a proof-of-principle detector has not yet been demonstrated. The second method employing a magnifying lens was used with a charge-coupled device and scintillator, and it also results in unacceptably small fields of view, on the order of 2 mm, and initial results demonstrated spatial resolution of order 15 μm , limited by the scintillator thickness. Finally the slit method requires scanning a slit over the region of interest, which provides high spatial resolution in one direction only, but still makes use of a large field of view. Initial tests demonstrated that a detector with an intrinsic 250 μm resolution, when coupled with a 10 μm slit yielded images with 10 μm spatial resolution, as shown in Figure 1. It is expected that this method can be further developed to achieve near a resolution near 1 μm .

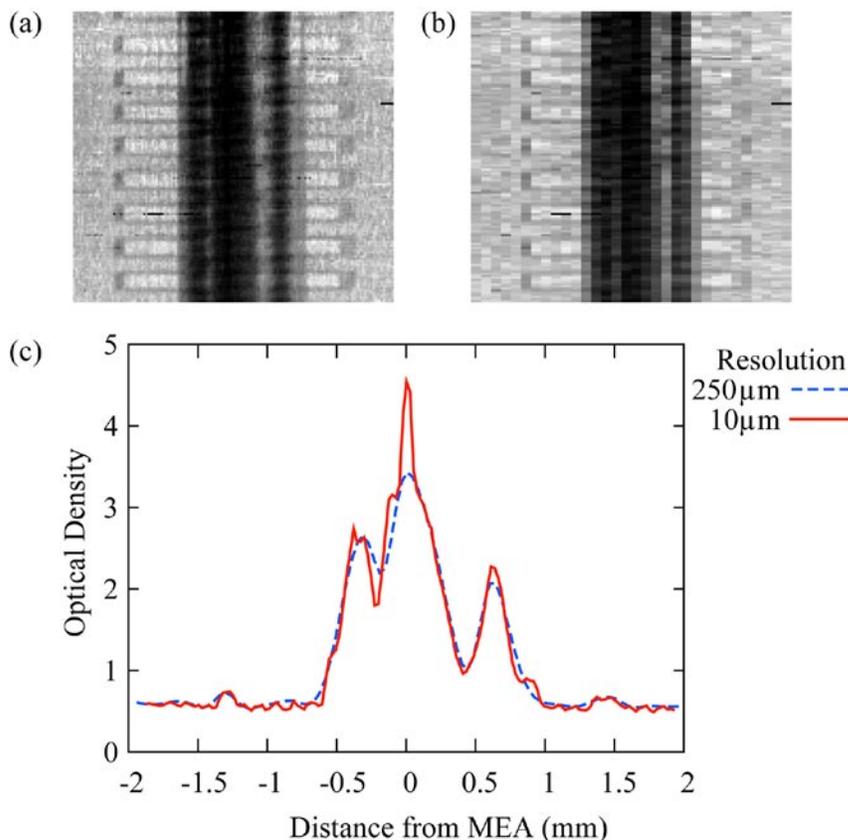

FIGURE 1. Demonstration of improved spatial resolution with a scanning slit. Image of a PEMFC test section is shown with an image spatial resolution of (a) 10 μm (b) 250 μm . (c) Comparison of the through-plane neutron attenuation demonstrating the improvement in resolution.

In collaboration with General Motors, a suite of performance and degradation studies have been carried out on full-scale, commercial hardware. The NIST beam is 26 cm in diameter, which allows nearly the entire full-scale fuel cell to be viewed at once. These full scale images were also captured with a high frame rate (up to 30 Hz) utilizing the amorphous silicon flat panel detector with spatial resolution of 0.25 mm. One output of this work shows the impact of channel surface treatment on water retention (Figure 2). Bipolar plates treated with a hydrophilic coating reduce both the overall water retention during operation and the

energy required to purge the active area for in preparation for cold/freeze start. In contrast, hydrophobic treatments increase the amount of water retained by the diffusion media and result in longer times to purge the active area for cold/freeze start. An innovative planar stack was designed to allow radiography studies of stack failure modes. Figure 3 shows the results of using this planar 4-cell stack to study the stability of the stack as a function of anode stoichiometry. This study observed that the cell with the highest DM saturation (Cell 3) is seen to be the first to fail. The other cells (Cells 1, 2 and 4) are seen to have more water in the channels and this channel water diverts gas flow into the DM thus reducing the DM saturation and reducing the electrode flooding. Repeated measurements showed that the cell that failed first varied, but that this cell was always the one that had the highest DM saturation.

Employing the 10 μm spatial resolution micro-channel plate detector, we have collaborated with the Los Alamos fuel cell team in studying flooding in

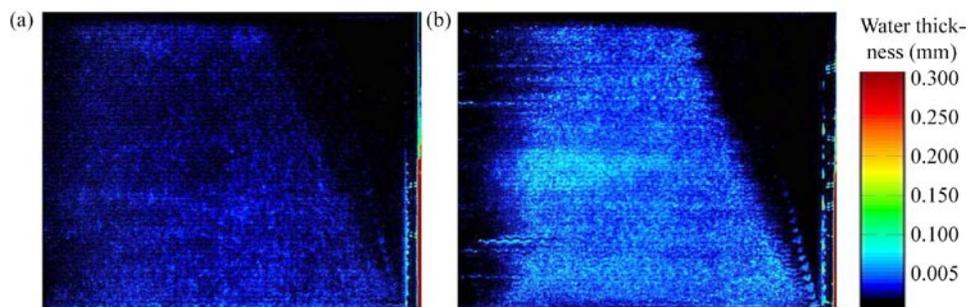

FIGURE 2. Water content of a test section with a (a) hydrophilic bipolar plate ($\theta_s = 100^\circ$) and a (b) hydrophobic bipolar plate ($\theta_s = 10^\circ$). The test section was operated at 0.1 A cm², 75°C, and anode (cathode) outlet relative humidity of 121% (108%).

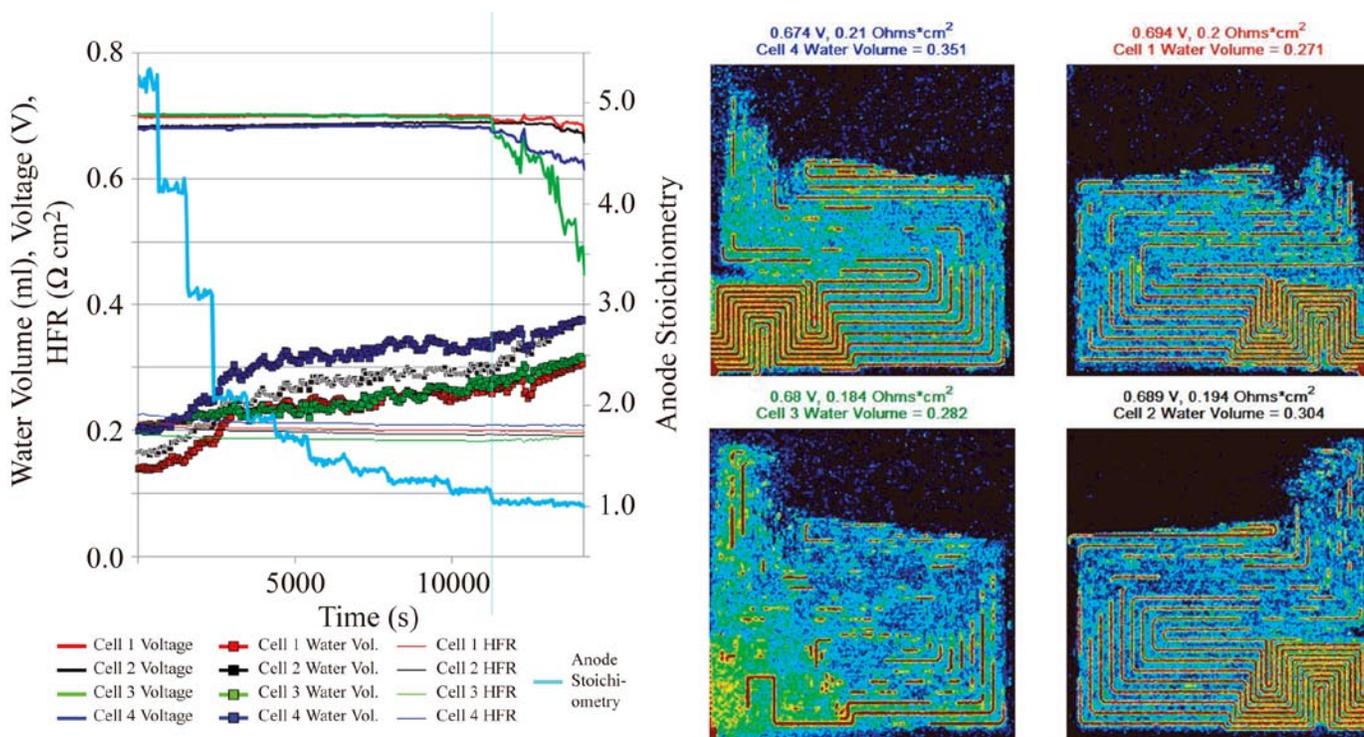

FIGURE 3. Correlation of water content with cell instability in a four-cell stack as a function of anode stoichiometry. The line plot is the voltage, water volume and high frequency resistance at 1 kHz for each cell as a function of the anode stoichiometry. The neutron images are from the point at which the anode stoichiometry drops to about 1, and show that Cell 3, which has the highest gas diffusion layer (GDL) saturation rather than the greatest overall water volume, fails first. The additional water content in Cells 1, 2 and 4 is due to larger channel water content, which diverts flow into the GDL and reduces GDL saturation.

a non-precious group metal (NPGM) oxygen reduction catalyst as well as studying the effects of test two accelerated stress tests (ASTs) on the through-plane water content. In the NPGM study, a polyaniline-derived catalyst was compared to a Pt-based catalyst with a similar thickness. It was seen that the NPGM catalyst retained significantly more water; thus one path to improving this catalysts performance may be to reduce its hydrophilicity.

The first AST was performed at a constant voltage hold of 1.3 V for 80 min, followed by operation and imaging at a constant current of 0.8 A/cm² for 60 min, followed finally by a polarization curve measurement. The goal of this study was to investigate the role of a microporous layer (MPL) on the water transport during degradation. Previous studies have shown that during corrosion the catalyst layer/GDL becomes more hydrophilic, therefore it was expected that water retention due to the increase in hydrophilicity would be a primary contribution to loss of performance during corrosion. Since the corrosion results in a higher overpotential, operation at constant current generates more heat at the membrane. This temperature gradient efficiently transports the water from the catalyst layer to the channel drying out the test section and is a greater effect than the increased hydrophilicity of the corroded catalyst. However, the presence of the MPL improved the test section durability with less water overall in the test section at all points in the AST. The reduced water content due to the catalyst MPL is believed to be the primary factor that leads to less corrosion and better performance.

In the second AST, a test section representing a standard cell from Ballard was cycled under the following conditions: 30 s at 0.6 V, 60 s at 1.4 V, 100% relative

humidity, 80°C, 34.5 kPa backpressure, and constant gas flow rates of 1.5 lpm H₂ and 2.5 lpm air. Neutron images, electrochemical impedance spectroscopy (EIS), cyclic voltammetry (CV), and polarization curve measurements were acquired at intermediate cycles to assess the effects of the degradation. The neutron images were taken while operating the cell at a constant voltage of 0.6 V (not constant current as was done in the first AST). The CV data show a loss in electrochemical surface area up to 100 cycles followed by a more gradual loss beyond 100 cycles. The EIS and polarization curve data show only marked performance degradation after 500 cycles. As shown in Figure 4, the neutron images reveal that the water content initially increases during the first 50 AST cycles, but begins to reduce after 100 AST cycles. Additional experiments are planned using the second AST to better elucidate the corrosion mechanism that was observed by the early onset of the reduced water content.

Conclusions and Future Directions

- A range of water transport topics in commercial-sized stacks and small-scale hardware have been studied utilizing neutron imaging:
 - Hydrophilic coating on bipolar plates aids in efficient water removal.
 - Planar stack designs allow for testing and analyzing failure mechanisms in stacks.
 - Catalyst corrosion produces a larger thermal gradient enhancing water removal from the MEA.

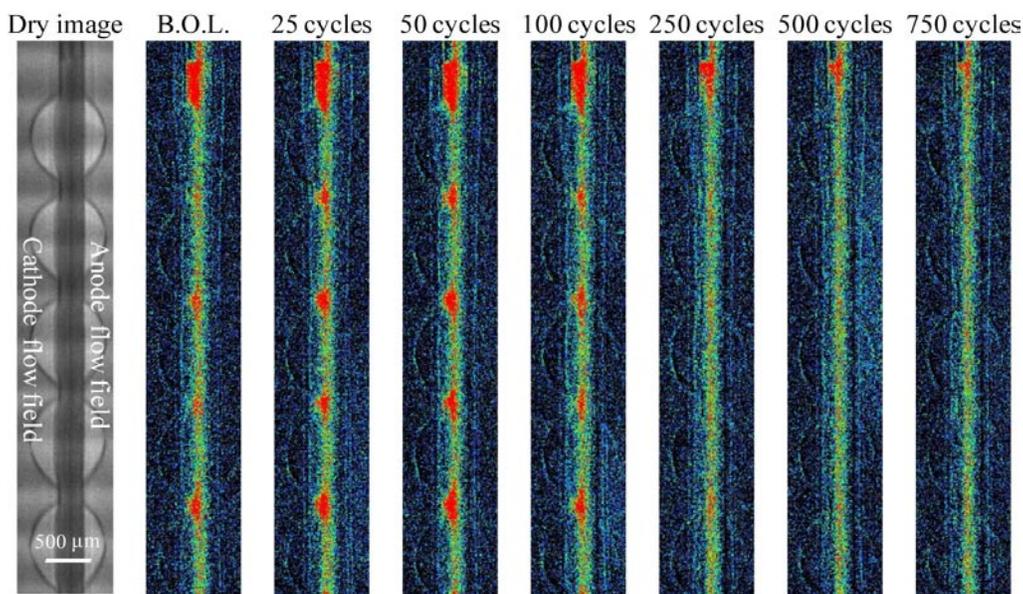

FIGURE 4. Neutron images at intermediary points in the AST cycle from beginning of life (BOL) through 700 cycles. The water content peaks between 25 and 50 cycles. Although the performance after 250 cycles is similar to the BOL, the water content in the cell has already been reduced.

- Future experiments will have enhanced resolution to resolve finer details of membrane and catalyst water profile:
 - Develop new high-resolution techniques to improve the spatial resolution to sub-10 μm with a final goal of 1 μm .
 - Perform experiments to measure and compare with models of water transport through the GDL/MPL/catalyst and membrane with sub-10 μm resolution.
- Expand avenues of fuel cell research allowing larger cells to be imaged with high spatial resolution and even higher temporal resolution:
 - Improve field of view while maintaining spatial resolution to look at larger fuel cells.
 - Provide higher frame rate capabilities up to 100 frames per second in response to user needs.
- Potentially enhance sensitivity of high resolution fuel cell imaging by adding a new cold neutron imaging capability using a new facility to be built for expansion of the NIST Center for Neutron Research.

E-mail: Nancy.Garland@ee.doe.gov

Project Start Date: October 2003
Project End Date: Project direction and
continuation determined annually by DOE

Fiscal Year (FY) 2011 Objectives

- Support technically, as directed by DOE, fuel cell component and system developers.
- Assess fuel cell materials and components and give feedback to customers.
- Assist the DOE Durability Working Group with the development of various new material durability testing protocols.
- Provide support to the U.S. Council for Automotive Research (USCAR) and the USCAR/DOE Fuel Cell Technology Team.
- Validate technical findings as directed by DOE.

Technical Barriers

This project can be directed to address any of technical barriers from the Fuel Cells section (3.4.4.2) of the Fuel Cell Technologies Program Multi-Year Research, Development and Demonstration Plan (MYRDDP), however it principally addresses:

- (A) Durability
- (B) Cost
- (C) Performance

Technical Targets

In this particular task, any of the technical targets in Table 3.4.4 of the MYRDDP may be addressed at any given time. Specifically, select tasks that apply to the technical targets in this project are listed below, while their status is listed in the Accomplishments section.

- Provide continued testing insight and advice as directed by the DOE.
- Develop and validate new durability test protocols.
- Offering technical assistance to USCAR and the USCAR/DOE Fuel Cell Technical Team.
- Participating in working groups and review meetings.

Approach

Our approach has consistently focused on collaborative-type interactions as guided by DOE. A large portion of this effort goes unpublished, for proprietary reasons. We have actively participated in the DOE Durability Working Group. Our efforts have been focused on developing durability protocols. More specifically, four protocols are being discussed: rotating disc electrode (RDE)/rotating ring disc electrode (RRDE) measurements of performance and durability of non-precious group metal (PGM) oxygen reduction reaction (ORR) electrocatalysts, ORR electrocatalysts performance and durability measurements in half cell with liquid electrolyte under RDE/RRDE conditions, protocols for evaluating alternative electro-catalyst supports for proton exchange membrane fuel cells, and start/stop protocols for durability life testing. However in this FY, we have continued to provide testing support and actively participated in developing test protocols.

FY 2011 Accomplishments

- Hosted numerous visitors to Los Alamos National Laboratory (LANL).
- Collaborated with multiple industrial, university, or laboratory partners.
- Provided testing to several DOE solicitation winners.
- Participated in the review and development of several durability protocols.
- Hosted LANL-Japanese National Institute of Advanced Industrial Science and Technology-New Energy and Industrial Technology Development Organization Workshop and chaired several sessions (LANL scientists presented, also).

Highlights

Figures 1-5 show some highlights of the technical assistance task for the 2011 FY.

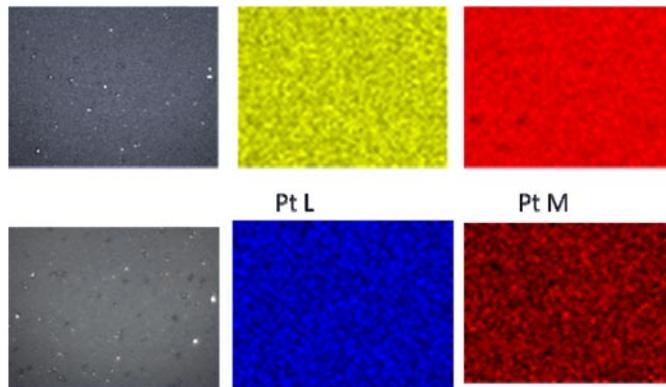

FIGURE 1. Scanning X-ray diffraction of commercial vendor membrane electrode assemblies (MEAs) using two Pt peaks at different energy provides complementary information: L lines show total Pt distribution (both sides of the MEA) and M lines show only one side of MEA.

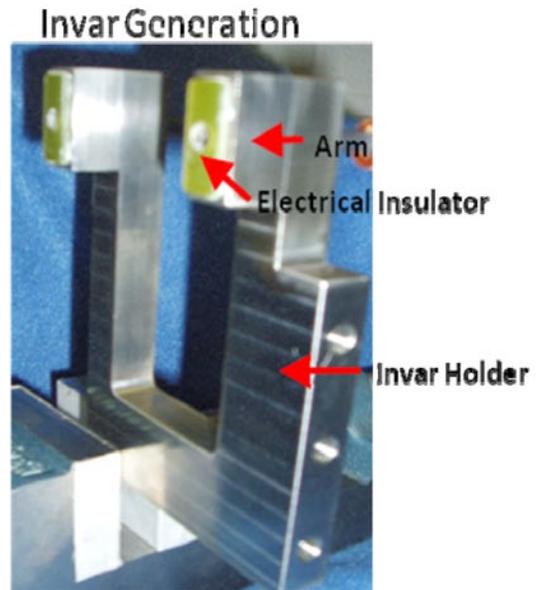

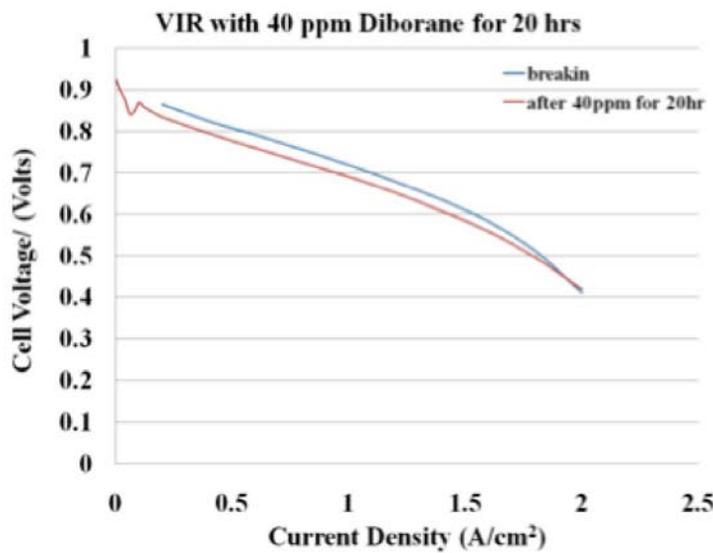

FIGURE 2. LANL designed, built, and provided a new and improved high-resolution fuel cell holder for neutron imaging at the National Institute of Standards and Technology (NIST). The new holder is notable for its uniquely low coefficient of thermal expansion. It has been provided to NIST to make available for all users.

Project End Date: Project continuation and direction determined annually by DOE

stationary and other fuel cell systems have an acceptable price point that is considerably higher than transportation systems.

Technical Targets

The Stationary Fuel Cell Modeling project will provide information about how achieving performance and cost targets for fuel cells in stationary applications could affect the competitiveness of fuel cells in stationary CHP and CCHP applications. The modeling effort will support the fuel cell MYRDDP technical and cost targets by evaluating realistic in situ building energy cost and emissions for CHP fuel cells that meet the targets. The values listed in Table 1, which is an excerpt of selected technical and cost targets for proton exchange membrane (PEM) fuel cell systems, are an example of the types of system characteristics that can be analyzed using the model. The modeling effort will also provide insight into the relative impacts of performance and cost targets on the overall lifecycle cost/benefit of CHP and CCHP installations.

Fiscal Year (FY) 2011 Objectives

- Model fuel cells in realistic combined heat and power (CHP) and combined cooling, heat and power (CCHP) applications to quantify the potential benefits of fuel cell-based distributed power for commercial buildings in the United States
- Identify optimal fuel cell sizes and control strategies based on analysis of the tradeoffs between manufacturing fuel cells that are perfectly matched to every application and fuel cells that are economical to manufacture.

Technical Barriers

This project addresses the following technical barriers from the Fuel Cell section of the Fuel Cell Technologies Program's Multi-Year Research, Development and Demonstration Plan (MYRDDP):

- (B) Cost
- (C) Performance

Even though the specific performance requirements differ from transportation applications, some of the technical challenges for stationary and other fuel cell systems are the same. For example, the overall cost of these fuel cell power systems must also be competitive with conventional technologies or offer enhanced capabilities. However,

Approach

The model must analyze the tradeoffs between manufacturing fuel cells that are perfectly matched to every application and fuel cells that are economical to manufacture. Therefore, two sub-functions must be optimized together: (1) a function to analyze fuel cells' interactions with various building types and occupancy patterns in various climates, and (2) a function to estimate the cost associated with manufacturing fuel cells of various types and sizes at various production rates. Figure 1 schematically illustrates the interactions between the model functions.

The project is divided into four tasks for 2011.

1. Literature review: Gather information about existing fuel cell and CHP/CCHP models with the goal of identifying useful modeling strategies and identifying potential benchmarks for model validation.
2. Collect building load and other input data: Initially, much of this effort will emphasize identifying data gaps and assessing data quality/needs.
3. Develop graphical user interface proof-of-concept design: Initial emphasis will define the output from the model to meet the overall objective.
4. Demonstrate proof-of-concept tool: The goal of this task is to produce a working model that is capable of providing preliminary results that are reasonably accurate by the end of FY 2011.

TABLE 1. Example Technical Targets for Stationary Fuel Cells That Will Be Evaluated in the Stationary Fuel Cell Model

Excerpted from the 2007 Multi-Year Research, Development and Demonstration Plan Table 3.4.4 Technical Targets: Integrated Stationary PEM Fuel Cell Power Systems (5-250kW) Operating on Reformate and 3.4.5 Technical Targets: Stationary PEM Fuel Cell Stack Systems (5-250 kW) Operating on Reformate				
Characteristic	Units	2003 Status	2005 Status	2011 Targets
Electrical Energy Efficiency @ Rated Power	%	30	32	40
CHP Energy Efficiency @ Rated Power	%	70	75	80
Fuel Cell Stack System Cost	\$/kWe	N/A	1,500	530
Transient Response Time (from 10% to 90% power)	seconds	<3	<3	<3
Durability @ <10% Rated Power Degradation	hours	15,000	20,000	40,000
Emissions (combined NOx, CO, SOx, hydrocarbon, particulates)	g/1,000 kWh	<8	<8	<1.5

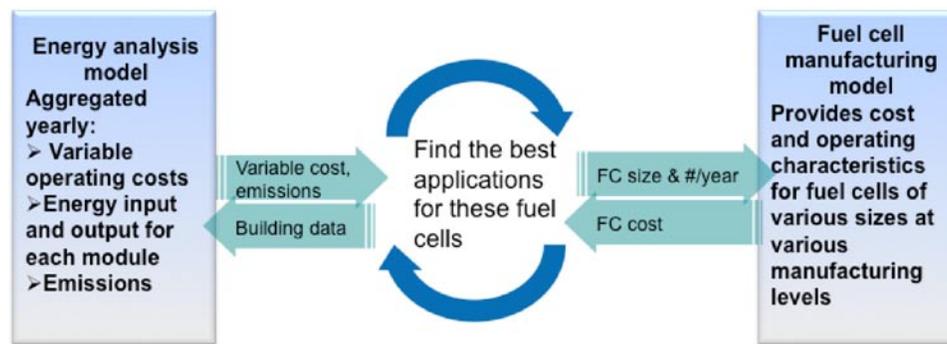

FIGURE 1. Interaction Between Fuel Cell CHP/CCHP Performance Model and Manufacturing Cost Model

FY 2011 Accomplishments

Tasks 1 and 2

- Existing models for benchmarking, partners, and reviewers were identified.
- Attributes for an initial set of buildings, climate, fuel prices, and emissions were collected and entered into an extensible database.
- Attributes of fuel cell manufacturing and performance were collected or estimated for an initial set of fuel cells (proton exchange membrane and solid oxide).

Tasks 3 and 4

- The layout and primary functional screens of the user interface were developed.
- Sub-modules were developed for the initial set of equipment.
- A flexible control strategy was developed.

Future Direction

In FY 2012, NREL will perform the following tasks:

1. Assemble full set of building inventory data and additional fuel cell models.
2. Continue verification and refinement of embedded models and model documentation.
3. Perform initial full-scale optimization analyses.

FY 2012 Planned Milestones

1. Complete draft stationary fuel cell model users guide and model documentation including:
 - Operation of the model including default values and acceptable ranges for input values.
 - Documentation of sources and meta-data for embedded databases and models.
 - Documentation of equations and validation of fuel cell and balance of plant models.
2. Compile detailed plan and prioritized list of proposed additions/enhancements to the model.

Potential Future Model Capabilities

- Interface with building models/or incorporate simple building modeling capability.
- Enhanced environmental analysis capabilities.
- Built-in comparison to other CHP technologies.
- Batteries and/or thermal storage.
- Multi-building/district heating scenarios.
- Hydrogen production for vehicles.

the Fuel Cell Technologies Program Multi-Year Research, Development, and Demonstration Plan:

- **Milestone 86:** Evaluate short stack against 2011 targets for operation over the full operating temperature range. (4Q, 2010): We are testing stacks from different developers and documenting their performance according to well-defined test protocols for comparison of the measured performance against DOE targets.
- **Milestone 87:** Test and evaluate fuel cell systems and components such as MEAs, short stacks, bipolar plates, catalysts, membranes, etc., and compare to targets. (1Q, 2011): We are testing fuel cell stacks, balance-of-plant components, and complete systems to document their performance for comparison to DOE targets.
- **Milestone 88:** Test and evaluate fuel cell systems and components such as MEAs, short stacks, bipolar plates, catalysts, membranes, etc., and compare to targets. (4Q, 2015): We are testing fuel cell stacks, balance-of-plant components, and complete systems to document their performance for comparison to DOE targets and to document the improvements made in meeting those targets.

Fiscal Year (FY) 2011 Objectives

- Provide DOE with an independent assessment of the performance of fuel cell systems and components developed under DOE contracts.
- Characterize and benchmark the performance of state-of-the-art commercial fuel cell technology available in the market.

Technical Barriers

This project addresses the following technical barriers from the Fuel Cells section (3.4) of the Fuel Cell Technologies Program Multi-Year Research, Development and Demonstration Plan:

- (A) Durability
- (C) Performance
- (D) Water Transport within the Stack
- (G) Start-up and Shut-down Time and Energy/Transient Operation

Contribution to Achievement of DOE Fuel Cells Milestones

This project will contribute to achievement of the following DOE milestones from the Fuel Cells section of

FY 2011 Accomplishments

- Characterized a 10-kW fuel cell stack from NedStack on both the U.S. and European Union (EU) test and aging protocols.
- There was no significant difference between the results obtained with the two different test protocols.

Introduction

This project helps DOE determine and document progress toward achieving its technical targets by providing an independent assessment of evolving fuel cell technology. In addition, in this project we develop standardized fuel cell testing procedures to aid in the evaluation of different stack technologies on a common basis. The procedures and methods used at the Argonne Fuel Cell Test Facility provide a means for easy comparison of the performance and expected life of the technology from different developers. In these procedures, the stack is characterized in terms of initial performance and durability. To further accelerate fuel cell technology developments, these procedures are compared with similar procedures developed by other national and international organizations.

The initial performance establishes a baseline for comparison as the fuel cell ages. The aging process is accelerated to yield a reasonable projection of life at constant power and under driving duty cycles in a reasonable amount of testing time. Periodically during the aging test, the test is interrupted and the stack performance is re-characterized. A life projection is then made by comparing the most recent performance characteristics with those measured earlier.

Approach

We have developed standardized fuel cell and stack test procedures to aid in the evaluation of different stack technologies. These test procedures characterize the stack in terms of initial performance (e.g., power and voltage vs. current, efficiency, hydrogen cross-over), durability, and low-temperature performance. The testing is repeated during and after defined aging under steady-state and potential or load cycling operations to determine performance decay over time.

The test facility is flexible enough to accommodate the unique needs of different fuel cell technologies. Modification and upgrading of the test facility is an ongoing process that is carried out in consultation with fuel cell developers and DOE.

Results

There is interest in the U.S. and in the EU to standardize testing protocols. It is hoped that with standardized protocols, fuel cell development will be accelerated and information exchange will be increased. Under the FCTESTNET framework program, the EU has developed a set of protocols it is proposing as standards. These protocols are being validated under the FCTES^{QA} program in a number of EU laboratories.

As part of our collaboration with FCTES^{QA}, we participated in a round-robin experiment where the results from different test sites are compared using a common fuel cell stack and the FCTES^{QA} test protocols for sequential polarization curves. To complete our work on comparing polarization protocols, we also tested the stack using the DOE protocols. The major differences between the EU and DOE protocols are the sequence of currents used and the portion of the polarization experiment that is reported as the resulting data. Figure 1 shows that the DOE protocol starts at open circuit, and then sequentially increases and decreases the stack current in turn. The FCTESTNET protocol, on the other hand, can start at almost any current setting. In prior work, we used the FCTESTNET example shown Figure 1. Here, the test protocol starts at about 50% of the rated current; the current then increases, decreases, and finally increases again.

For the current work, we used the FCTESTNET protocol shown schematically in Figure 2, which starts

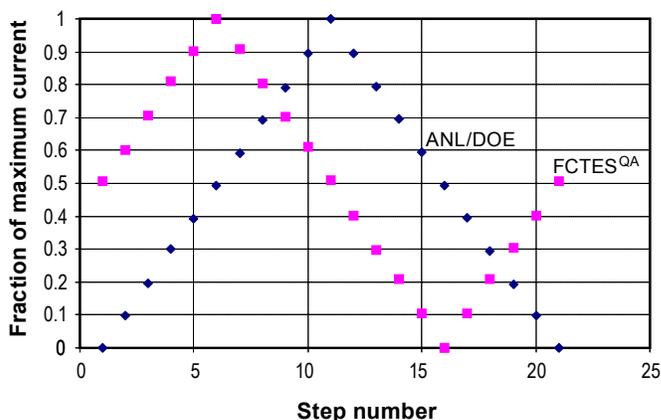

FIGURE 1. Sequence of current levels used in the polarization protocols developed by DOE and by FCTESTNET used in prior work.

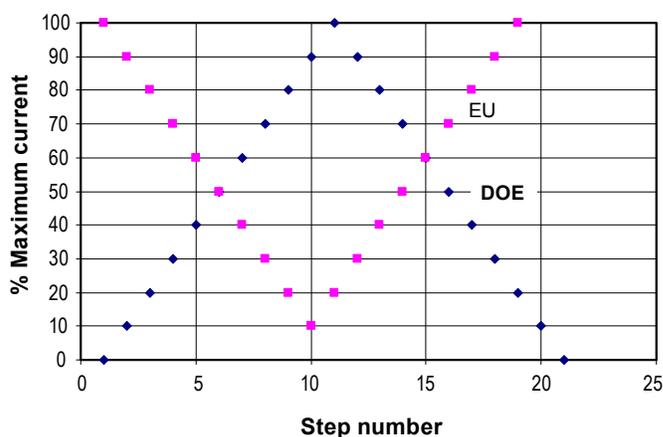

FIGURE 2. Sequence of current levels used in the polarization protocols developed by DOE and by FCTESTNET used in current work.

at 100% of the rated current before decreasing and then increasing. As before, the DOE protocol reports data from both the current-increasing and the current-decreasing sections. For the FCTESTNET protocol, only the results from the current-decreasing portion are reported.

Figure 3 shows the current-decreasing portion of the polarization curves obtained from the 75-cell, 10-kW stack using the two protocols. There was no significant difference between the two curves.

To further characterize the stack as well as the difference between the two protocols, we performed a temperature sensitivity test on the stack. Here, the area-specific resistance (ASR) of the stack was calculated from the polarization results measured at four temperatures, 52.5, 57.5, 62.5 and 67.5°C, and at 1,000 mA/cm². These results are summarized in Figure 4.

A linear regression of the data shown in Figure 4 was performed. The regression coefficients, also shown in Figure 4, were greater than 0.95, indicating a strong

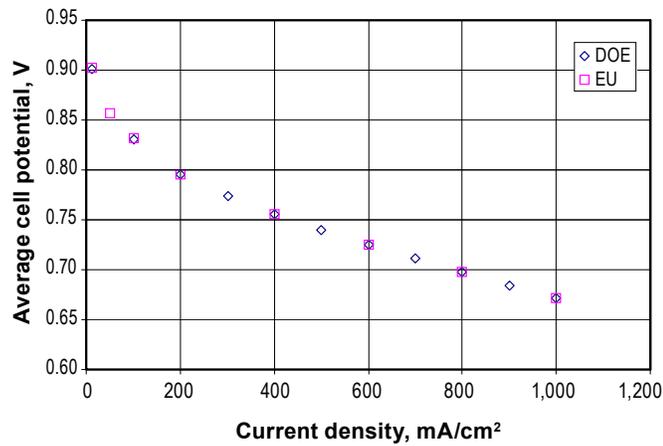

FIGURE 3. Comparison of polarization curves using the current levels and sequence shown in Figure 2. Test conditions: temperature, 62.5°C, air pressure, 0.7 barg; fuel pressure, 0.2 barg; air/fuel stoichiometries, 3/2; inlet gas relative humidity, 85%.

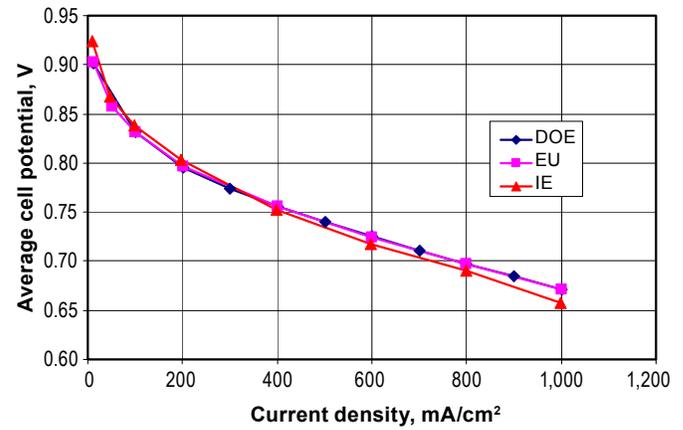

FIGURE 5. Polarization results obtained at ANL and at JRC’s Institute for Energy. The curves denoted as DOE and EU were obtained at ANL using the DOE and EU protocols, respectively, under the conditions described under Figure 3. The curve denoted as IE was obtained at JRC’s Institute for Energy using the same conditions.

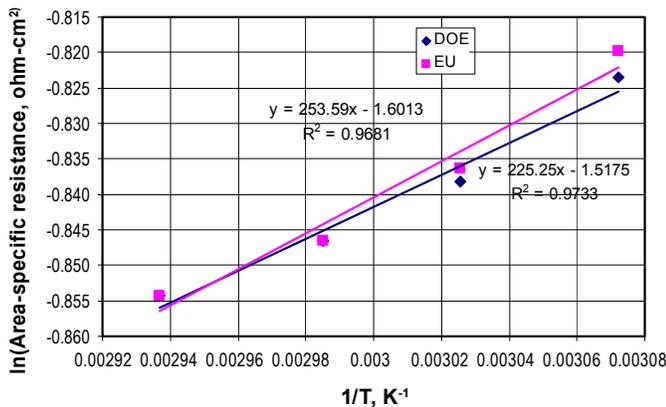

FIGURE 4. Arrhenius plot of stack area-specific resistance measured by both the DOE and EU protocols at 1000 mA/cm². The same conditions as described under Figure 3 were used, with the exception of stack temperature.

linear relationship between \ln ASR and reciprocal absolute temperature. Thus, the results are consistent with Arrhenius kinetics. Figure 4 also shows that there was a slight difference between the two regression lines, which was due to slight differences (<0.5%) in the calculated values of the ASR.

Finally, we compared our results using the conditions described in Figure 3 with those obtained at JRC’s Institute for Energy, as shown in Figure 5. The results showed that, at 1,000 mA/cm², there was ~14 mV difference in the average cell potential. It is possible that the slightly higher performance obtained in the testing at ANL versus results obtained at JRC are due to a more precise control of the humidification levels.

Additional work is needed to evaluate the effects of accelerated aging protocols developed by DOE and FCTESTNET. There may be differences in stress levels under the two testing protocols, which, in turn, may cause differences in aging characteristics. Since we will perform these tests sequentially on the same stack, there may be additional effects in the data, such as path dependency. We will perform the same aging experiments in reverse order to determine if there is path dependency in the results.

Conclusions and Future Directions

- We are collaborating with the EU’s FCTESTNET program to compare and validate the fuel cell test protocols being developed by the EU and the DOE. Preliminary results from the testing of a 10-kW stack showed that there was no significant difference between the polarization curves obtained under these two different protocols.
- In future work we will continue to characterize DOE fuel cell contract deliverables, as well as benchmark other fuel cell technologies.
- We will continue to collaborate with other fuel cell testing laboratories, such as the Institute for Energy (Netherlands). Additionally, as part of our work in TC/105/Work Group 11, we will begin to draft a technical specification for single-cell solid oxide fuel cell testing.

Project Start Date: July 20, 2009

Project End Date: 2013

Fiscal Year (FY) 2011 Objectives

Our overall objective is to decrease the cost associated with system components without compromising function, fuel cell performance, or durability. Our specific project objectives are:

- Identify and quantify system derived contaminants.
- Develop ex situ and in situ test methods to study system components.
- Identify severity of system contaminants and impact of operating conditions.
- Identify poisoning mechanisms and investigate mitigation strategies.
- Develop models/predictive capability.
- Develop material/component catalogs based on system contaminant potential to guide system developers on future material selection.
- Disseminate knowledge gained to the community.

Technical Barriers

This project addresses the following technical barriers from the Fuel Cells section (3.4.4) of the Fuel Cell

Technologies Program's Multi-Year Research, Development and Demonstration Plan:

- (A) Durability
- (B) Cost

Technical Targets

This project focuses on quantifying the impact of system contaminants on fuel cell performance and durability. Insights gained from these studies will be applied toward the development of a catalog of system component materials that help meet the following DOE 2010 targets:

- Cost: \$30/kW for transportation, \$750/kW for stationary
- Lifetime: 5000 hours for transportation, 40,000 hours for stationary

Accomplishments

- Selected 50 relevant balance-of-plant (BOP) materials based on physical properties, functionality in a fuel cell environment, and cost.
- Established a standard set of experimental protocols for analysis, including leaching, cyclic voltammetry, analytical characterization and in situ fuel cell protocol(s).
- Benchmarked testing protocols and equipment among the different labs.
- Preliminary ex situ screening of 19 polymeric structural plastics.
- Identified leachants via gas chromatography-mass spectroscopy (GC-MS) and selected a few model species for further study.
- Developed a clear long-term project plan with gates and strategies for selecting materials for in-depth fuel cell studies, model species studies, durability testing, and modeling.

Introduction

Cost and durability issues of polymer electrolyte membrane fuel cell (PEMFC) systems have been challenging in the fuel cell industry. The cost of the BOP (\$51/kW in 2010 [1]) system has risen in importance with decreasing fuel cell stack cost (\$25/kW in 2010 [1] compared to \$65/kW in 2006 [2]). Lowering the cost of PEMFC system components requires understanding of the materials used in the system components and the contaminants that are derived from them, which have been shown to affect the performance and

durability of fuel cell systems. Unfortunately, there are many possible contamination sources from system components [3-5]. Currently deployed, high-cost, limited-production systems are using expensive materials for system components. In order to make fuel cell systems commercially competitive, the cost of the BOP components needs to be reduced without sacrificing performance and durability. Fuel cell durability requirements limit the performance loss due to contaminants to at most a few mV over required lifetimes (thousands of hours), which means close to zero impact for system contaminants.

As catalyst loadings decrease and membranes are made thinner (both are current trends in automotive fuel cell research and development), operation of fuel cells becomes even more susceptible to contaminants. In consumer automotive markets, low-cost materials are typically required but lower cost typically implies higher contamination potential. The results of this project will provide the information necessary to help the fuel cell industry make informed decisions regarding cost of specific materials versus the potential contaminant impact on fuel cell performance and durability.

Approach

Our goal is to provide an increased understanding of fuel cell system contaminants and help provide guidance in the implementation, and where necessary, the development of system materials that will help enable fuel cell commercialization. While much attention has been paid to air and fuel contaminants, system contaminants have received very limited attention publicly and very little has been publicly reported [6-9]. Our approach is to perform parametric studies to characterize the effects of system contaminants on fuel cell performance and durability; as well as to identify poisoning mechanisms, recommend mitigation strategies, develop predictive modeling, and disseminate material catalogs that benefit the fuel cell industry in making cost-benefit analyses of system components. We are identifying and quantifying potential contaminants derived from stack/component fabrication materials and quickly screening the impact of the leachants on fuel cell catalyst and membrane via ex situ tests. Model compounds capable of replicating the deleterious impact of system-based contaminants are also being studied. Developing standard test protocols to evaluate materials is important as this approach will allow for broader studies to be performed. Furthermore, information obtained from ex situ methods is being validated with in situ testing.

Our system materials selection is based on properties such as exposed surface area, total mass or volume in a system, fluid contact, function, cost, and performance implications. Current material prioritization and selection to study is based on perceived impact of potential system contaminants (based on GM internal knowledge): structural materials, elastomers for seals and (sub)gaskets, assembly

aids (adhesives, lubricants), membrane degradation products, bipolar/end plates, and ions from catalyst alloys. Our project has a strong polymer focus, as much of the system is polymer based. Furthermore, we are studying commercially available, commodity materials. These materials are generally developed for other applications, where common additives/processing aids may not be a concern, but may present problems for fuel cells.

Results

We completed benchmarking of solution conductivity and total organic content (TOC) techniques, using the leachant solutions generated at GM for two polyphthalamide (PPA) structural materials (Dupont Zytel HTN51G35 HSLR[®] and Zytel HTN52G35 HSL[®]). As shown in Figure 1, reproducibility among the different labs for these techniques is consistent. Similar benchmarking was carried out at NREL and GM for GC-MS and inductively coupled plasma – optical emission spectroscopy; consistent reproducibility was found.

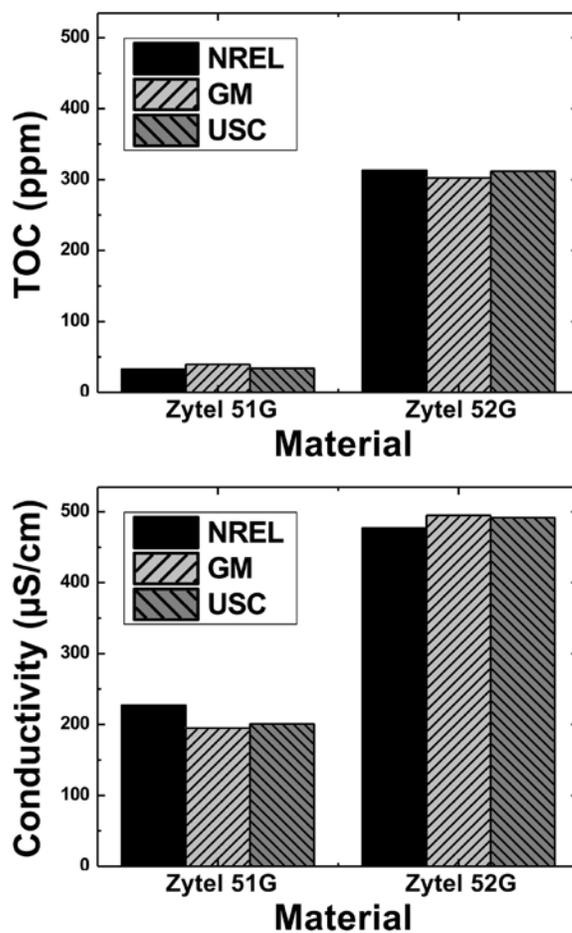

FIGURE 1. The TOC (upper) and solution conductivity (lower) measurements were carried out at NREL, GM, and USC. Reproducibility was consistent among the three labs.

We are screening 19 commercially available structural materials for their potential impact as system contaminants in fuel cell system. They are from the low cost Nylon™ family (polyamide and PPA) and the relatively more expensive polysulfones (PSU), polyphenylenesulfides (PPS) and polyphenylsulfones (PPSU) families. These structural materials underwent leaching protocols (soaked in de-ionized water at 90°C) for six weeks to extract potential contaminants from the parent materials into solution. Figure 2 summarizes the TOC and solution conductivity of these structural materials. As shown, the materials that have high levels of organic leachants do not necessarily have high ionic content. Preferred materials would have low TOC and conductivity values, as highlighted by the circle on the figure.

Initial screening of the leachants after one week of soaking shows that the PPS, PSU and PPSU families are relatively clean materials, with low TOCs and solution conductivities. Also, the liquid GC-MS method did not detect any organic leachants for these materials.

For the polyamide family (PA6, PA6,6, PPA), three common organic species were identified by liquid injection

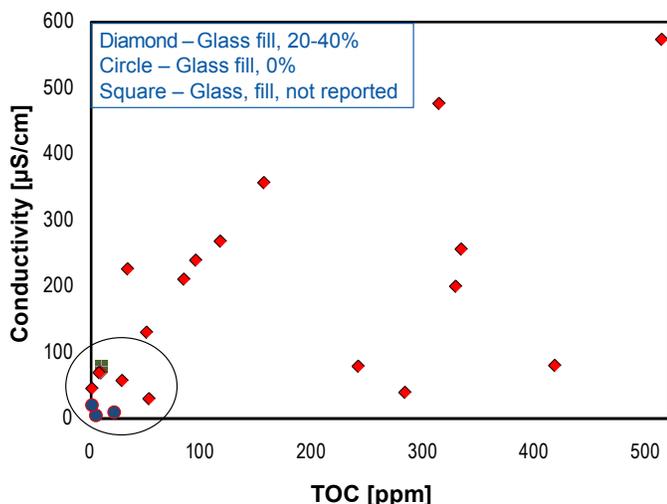

FIGURE 2. Solution conductivity vs. TOC plot for all the structural materials screened to-date. Each point represents a different material tested. Target materials appear at the bottom left corner: low TOC and low solution conductivity.

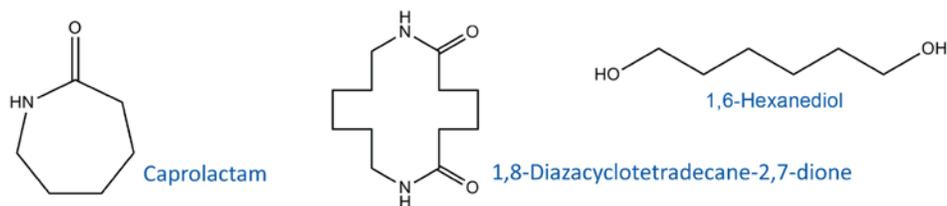

FIGURE 3. Chemical structure of the organic species identified in polyamide family of polymers by liquid GC-MS.

GC-MS: 1,8-diazacyclotetradecane-2,7-dione [DCTDD], caprolactam, and 1,6-hexanediol. The chemical structures of these species are shown in Figure 3. These species will be used as model compounds for further study. It is likely that DCTDD is a Nylon™ decomposition product and/or trapped waste product from the synthetic condensation reaction of adipic acid and hexamethylenediamine. Caprolactam is likely a residual monomer from a ring opening polymerization to synthesize PA6. Knowing the chemistry of the parent polymer and the polymer synthesis, it is understandable where these organic compounds originate from.

Conclusions and Future Directions

- We selected a complete set of relevant BOP materials for system contaminant studies based on the level of perceived impact (physical property, function and cost).
- We developed and benchmarked ex situ characterization methods and protocols for screening potential system contaminants.
- We benchmarked fuel cell hardware, test equipment and protocol between the different team members.
- We screened 19 structural materials and identified and quantified the organic and ionic contaminants present.
- We will establish correlations between analytical screening of extract solutions, cyclic voltammetry results, and fuel cell performance loss.
- We will screen the other selected structural materials, assembly aids (adhesives, lubricants), and elastomers for seals and gaskets.
- We will continue to identify and initiate screening of model compounds.
- We will initiate gas-phase durability testing and membrane degradation by-products study.

- United Technologies Corporation – Hamilton Sundstrand, Windsor Locks, CT

Project Start Date: March 1, 2007
Project End Date: August 31, 2011

Fiscal Year (FY) 2011 Objectives

- Identify the specific impurities and impurity families and their concentrations present in the fuel stream.
- Develop analytical chemistry protocols and tools to detect the nature and fate of contaminating species within fuel cells.
- Determine through controlled laboratory experimentation and literature study the main drivers for voltage decay.
- Develop impurity analytical models and computer simulations that explain and predict these effects.
- Validate impurity models through single cell experimentation using standardized test protocols.
- Develop and validate novel technologies for mitigating the effects of contamination on fuel cell performance.
- Disseminate results through outreach activities.

Technical Barriers

This project addresses the following technical barriers from the Fuel Cells section (3.4.4) of the Fuel Cell Technologies Program Multi-Year Research, Development and Demonstration Plan:

(A) Durability

Technical Targets

This project is conducting fundamental research into the effects of impurities on fuel cell performance and durability. This activity broadly supports the following technical targets established by DOE:

- By 2010, develop a 60% peak-efficient, durable, direct hydrogen fuel cell power system for transportation at a cost of \$45/kW; by 2015, a cost of \$30/kW.
- By 2011, develop a distributed generation PEM fuel cell system operating on natural gas or liquefied petroleum gas that achieves 40% electrical efficiency and 40,000 hours durability at \$750/kW.

FY 2011 Accomplishments

- Hydrocarbon Testing
 - Completed testing of acetaldehyde and formic acid up to a concentration of 100 ppm showing little effect of acetaldehyde on fuel cell performance but a significant effect of formic acid on fuel cell performance.
 - Developed a better understanding of membrane electrode assembly (MEA) variability and the effects of this factor on impurities testing.
 - Developed analytical procedures for evaluating concentrations of acetaldehyde, formic acid, and formaldehyde in the fuel stream.
 - Developed mixing protocols for injecting specific concentrations of acetaldehyde, formic acid and formaldehyde into the fuel stream.
- Other Impurities
 - Evaluated effects of pertinent cations on the physico-chemical properties of Nafion[®].
 - Completed testing of cells with various concentrations of ammonia in the fuel stream.
 - Developed a multi-dimensional model predicting the effects of cationic contaminants on polymer electrolyte fuel cells (PEFCs).
- Mixtures
 - Demonstrated fuel cell tolerance to a hydrogen fuel stream having a composition similar to that of

the International Organization for Standardization (ISO) fuel quality standard.

Introduction

Polymer electrolyte membrane (PEM) fuel cells show significant promise in providing efficient, clean power for stationary and transportation applications. The technology has shown limitations relative to long-term durability goals, particularly with regard to the operational lifetime of MEAs. One of the key causes for this is the introduction of impurities into the fuel stream that impacts the functionality of ion exchange groups within the electrolyte, degrade catalyst activity, and function as diluents causing the cell voltage to degrade.

The initial technical issues being addressed concern the identification of impurity species located in the fuel stream that may have an effect on overall fuel cell performance, and evaluation of these effects against standard test protocols. The U.S. Fuel Cell Council in conjunction with Japanese Automobile Research Institute and others have been developing hydrogen quality standards as well as procedures for contaminant testing of PEM fuel cells. These studies provide the background and basis for the initiation of our research.

Approach

This project is focused on the experimental determination of the effects of key impurities on the performance of PEM fuel cells. Experimental data collected from formalized test protocols will be leveraged to create mathematical models that predict the performance of PEM fuel cells that are exposed to specific contaminant streams. These models will be validated through laboratory experimentation and will be utilized to develop novel technologies for mitigating the effects of contamination on fuel cell performance. Results will be publicly disseminated through papers, conference presentations, and other means.

Results

Hydrocarbon Impurities

Based on input from working groups and industry, our team has focused our efforts on the evaluation of hydrocarbons and halogenated compounds using very specific test protocols developed as part of a multi-laboratory collaborative effort. Our strategy is to evaluate molecules that may be present in a candidate hydrogen fuel stream in order to evaluate the effects of functionality and molecular size (eg. number of carbon atoms).

In support of this, our team has developed techniques to prepare accurate mixtures of impurities in hydrogen and to determine the level of impurities entering the fuel cell through the hydrogen stream. A gas chromatograph has been utilized to characterize both the mixtures entering the fuel cell and those exiting the fuel cell in an effort to assess accumulation and reaction of impurity species within the fuel cell reactor. While previous studies conducted by our group have focused on the evaluation of either gaseous or volatile liquids, recent studies have centered around the development of methods for mixing and analyzing less volatile liquids such as acetaldehyde, formic acid and formaldehyde. Figure 1 shows a saturator apparatus that we have developed to accomplish this task.

Previous testing had been completed using methane, ethane, ethylene, acetaldehyde, and formic acid as the primary fuel stream impurity and later extended to include a mixture of benzene, toluene and CO. Testing has been established as a series of 100-hour test runs using up to 5% of the impurity in the fuel stream with the cell construction as defined in Table 1.

Testing was conducted at 200, 600, 800 and 1,000 mA/cm² with standard test conditions defined in Table 2. Conditions were modified as defined to achieve better performance stability during testing.

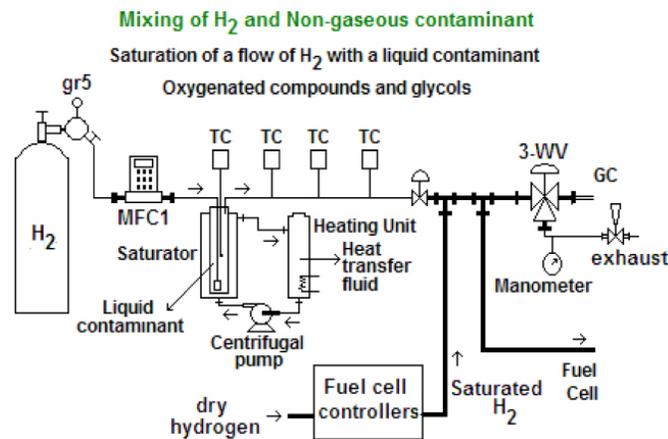

FIGURE 1. Gas Mixing Set-Up for Liquid Hydrocarbons

TABLE 1. Test Cell Definition

Parameter	Early	Intermediate	Recent
Membrane	Nafion [®]	Nafion [®] 212	PRIMEA

Flow Rate (A/C)	Commensurate with current density		
Pressure (psig) (A/C)	25 / 25	25 / 25	7 / 7

A - anode; C - cathode

Ethylene

Testing of the effect of ethylene (C_2H_4) on cell performance was reinvestigated at concentrations of 1% and 5%. These tests were performed to validate previous data obtained with earlier MEAs. No significant effect on cell performance was found during these tests.

Acetaldehyde

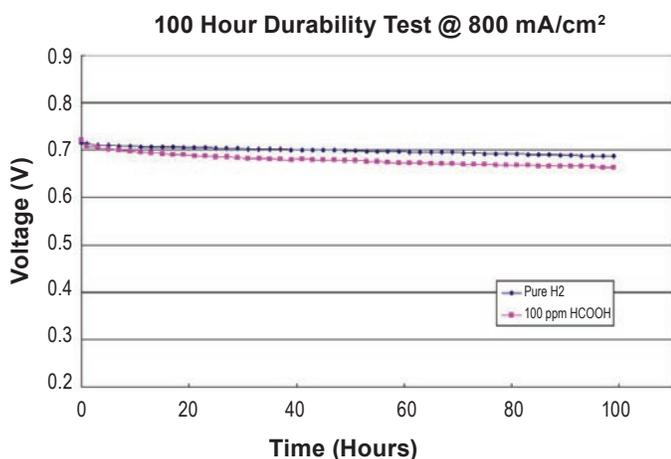

Testing of the effect of acetaldehyde (CH_3CHO) on cell performance was investigated at a concentration of 30 ppm. An immediate, but small drop of 20 mV at 800 mA/cm² and 50 mV at 1,000 mA/cm² was observed with addition of the impurity.

Benzene, Toluene, CO Mixture

The effect of benzene (C_6H_6), toluene (C_7H_8) and CO on fuel cell performance was investigated at an impurity concentration of 10 ppm, 10 ppm and 1 ppm, respectively. Testing showed no significant effect of cell performance during the 100 hour durability test shown in Figure 2.

Hydrogen Pump Studies

NH_3 contamination on PEFCs was investigated with pseudo reversible hydrogen electrodes (pseudo-RHEs).

**FIGURE 2.** Durability Test Using 100 ppm Formic Acid

It was found that NH_4^+ can affect the anode causing an increase of the overpotential in a hydrogen pump test. Figure 3 shows the overpotential variations of the anode and the cathode respectively during contamination and recovery. It is seen that 50 ppm NH_3 in H_2 can significantly affect the electrochemical kinetics on the electrodes. The initial drop of the overpotentials is due to the poisoning effect of NH_4^+ on pseudo-RHEs.

Raman Spectroscopy and Gas Chromatograph-Mass Spectroscopy Studies

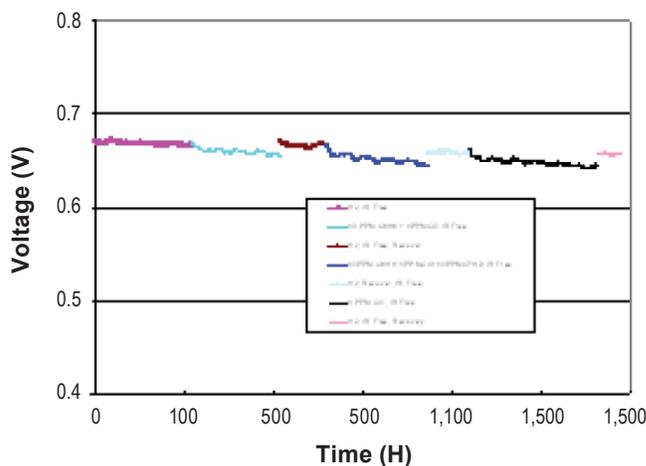

An investigation of gas diffusion layers (GDLs) revealed minor organic impurities left over from the manufacturing process were still present on the microporous layer of the GDLs. It was found that baking the GDLs would volatilize these compounds and clean the surface of organic impurities without damage to the GDLs.

Rotating Disk Electrode

Testing was conducted to further understand the mechanism of formic acid contamination of cell performance. It was found that the concentration of formic acid and presence of hydrogen impacted the oxidation of formic acid as seen in Figure 4. Testing to date has indicated little effect of simple hydrocarbon species on fuel cell performance; however, more complex species do show some performance effects.

Evaluation of Fuel Quality Standards

A model solution of the proposed hydrogen fuel quality ISO standard was evaluated in an operating cell. Results shown in Figure 5 indicate that 100-hour performance was similar to that obtained using pure hydrogen. However, tests run at a contaminant concentration of five times the proposed ISO standard showed significantly higher performance loss over time.

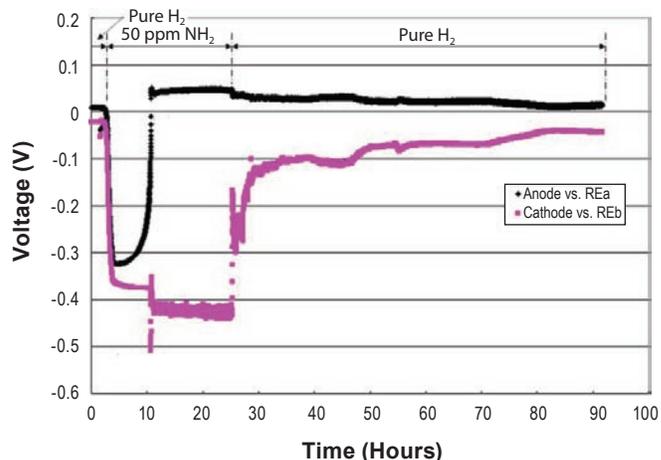

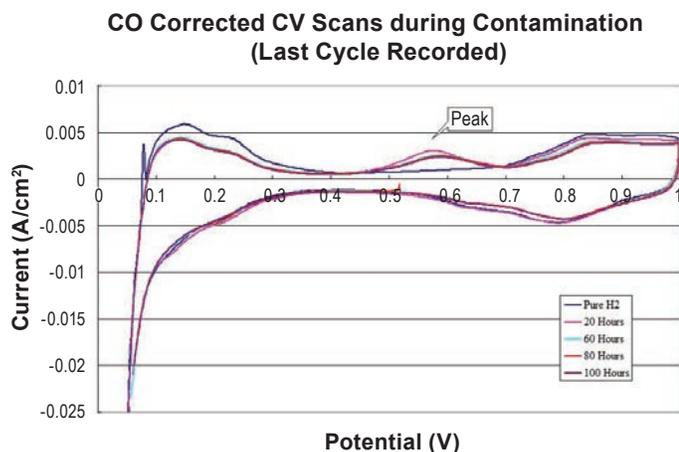

FIGURE 3. The Overpotentials versus RHEs Measured during NH₃ Contamination and Recovery of a 25 cm² MEA

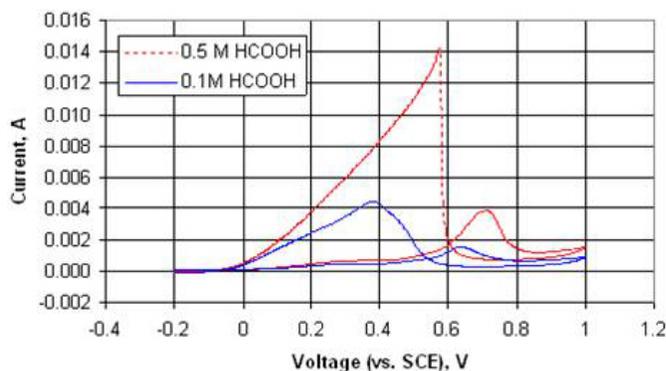

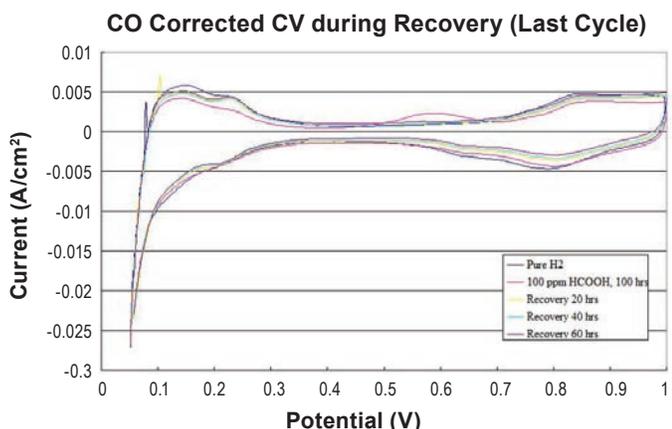

FIGURE 4. Cyclic Voltammetry of 0.1 M and 0.5 M Formic Acid in 0.2 M Sulfuric Acid, No Hydrogen Bubbling

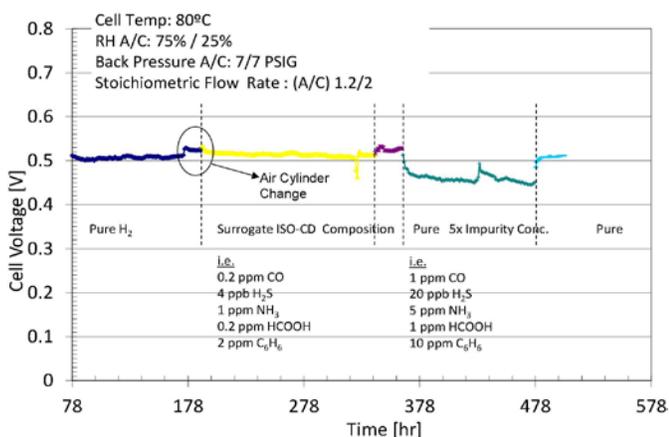

FIGURE 5. Fuel Cell Performance Comparing Pure Hydrogen Feed to Mixtures Emulating the Proposed ISO Fuel Quality Standard, and Contaminant Levels of Five Times the Standard

Conclusions and Future Directions

Conclusions

- Simple hydrocarbons including methane, ethane, ethylene and acetaldehyde do not significantly affect fuel cell performance.
- Formic acid impurities do show an appreciable affect on performance possibly due to adsorption on the electrode surface as well as the formation of reaction byproducts such as CO.
- A multi-component cationic transport model has been created and validated against experimental data.
- Testing with a model hydrogen mixture having chemistry similar to the hydrogen quality standard did not result in significant performance degradation.

Future Directions

- Comprehensive evaluation of formic acid and formaldehyde to support ISO standard development:
 - Continued testing using standard test protocols, MEAs.
 - Target low catalyst loadings (reduction from 0.4 mg/cm² to 0.1 mg/cm²).
 - Develop an understanding of mechanism for performance impact.
 - Modeling of effects/sharing of data.
- Extension to simple halogenated compounds.
- Continued study of effects of cations on membrane properties.
 - Application relevant contamination types/levels.
 - Commercially relevant membranes.
 - Modeling of effects/sharing of data.

tests conducted under high concentrations and using derived mechanistic understanding to increase these tolerance limits with fuel cell mitigation strategies applicable during operation or maintenance cycles.

- Durability: 5,000 h under cycling conditions
- Performance: 60/50 energy efficiency under 25/100% rated power

FY 2011 Accomplishments

- Identified more than 260 airborne contaminants and completed first tier down selection using six qualitative selection criteria including absence of prior data.
- Two quantitative cell performance ranking criteria were devised and the first tier list is currently being prioritized for detailed tests with varied operating conditions.

Introduction

The composition of atmospheric air cannot be controlled and typically includes contaminants. Proton exchange membrane fuel cells operated with ambient air are therefore susceptible to deleterious effects which include decreased cell performance and durability [1]. Numerous air contaminants have not yet been tested in fuel cells and consequently their effects are unknown. This increases the risk of failure for fuel cell systems and thus jeopardizes their introduction into the market. A significant amount of resources is required to characterize the effect of each species on fuel cell performance. Therefore, a method for species down selection is essential to keep the research scope within feasible limits. In this project, airborne contaminants were identified from a variety of sources and down-selected to a manageable yet representative group (first tier). Screening tests were conducted on the first tier contaminants to determine their effects on performance and the ability of the fuel cell to self recover after contaminant exposure. These factors were accounted for with two quantitative cell performance ranking criteria which were used for a second tier down selection. The results of these tests will facilitate the design of mitigation methods.

Approach

Contaminants are separated into three classes (gaseous species, foreign cations and solids) because testing requires different injection strategies and hardware. Key project team organizations are focusing on specific contaminant classes to minimize time consuming benchmarking activities and capabilities duplication. Gaseous species have already been identified and down selected (first tier, Table 1). All

Fiscal Year (FY) 2011 Objectives

Mitigation of the unknown effects of many airborne contaminants on membrane/electrode assembly materials, adversely impacting system performance and durability:

- Characterize, analyze, understand and prevent the effects of airborne contaminants.
- Disseminate this information in a useful form to industry and other end users.

Technical Barriers

This project addresses the following technical barriers from the Fuel Cells section of the Fuel Cell Technologies Program Multi-Year Research, Development and Demonstration Plan:

- (A) Durability
- (C) Performance

Technical Targets

The following 2015 transportation technical targets will be addressed by determining contaminant tolerance limits leading to negligible performance losses by extrapolation of

TABLE 1. Down-Selected Gaseous Airborne Contaminants and Some of their Characteristics

Contaminants			Annual maximum concentration (ppm carbon)*			Source	OSHA PEL (ppm)**
Hydrocarbon functionality	Common name	Formula	1 h average	3 h average	24 h average

selected contaminants will be confirmed by a representative interest group including industry, government and advocacy organizations. Fuel cell performance screening tests will be used to down select contaminants for more detailed studies (second tier) that include variations in key operating conditions (contaminant concentration, current density, temperature, relative humidity). Pressure and stoichiometry are not considered. Pressure represents an alternative to a

gaseous concentration change and is not relevant for ionic or solid contaminants. Stoichiometry is irrelevant because the contaminant concentration is approximately constant within the fuel cell based on transport and contamination processes time scales arguments. The project ensures that all contaminant sources are studied. Fuel contaminants were previously studied whereas system contaminants released by

fuel cell materials are currently being investigated in another DOE-funded project.

Results

Species down selection was initially completed on the basis of six criteria (first tier): i) atmospheric presence at a significant level, ii) expectation of reactivity within the fuel cell, iii) absence of recorded data, iv) largest range in chemical functionalities, v) compound toxicity, and vi) suggestions given by project monitors or the fuel cell community. These criteria were sufficient to create a shorter list of 19 contaminants (Table 1) from the larger list of 260+ candidates.

Table 1 shows that most contaminants are organic and are grouped within 12 different chemical functionality classes. Inorganic contaminants are only represented by ozone. All contaminants also originate from large scale industries with production levels exceeding in many cases a million ton per year.

Figures 1 and 2 results show a wide variety of contaminant behaviors. Acetonitrile demonstrates a significant effect but the performance is completely restored after exposure. Other behaviors include: absence of an effect (trichlorofluoromethane), significant effect with an incomplete recovery after exposure (bromomethane), significant effect with a recovery exceeding the initial loss (acetaldehyde). Contamination and recovery time scales also significantly vary within a <1 h to ~20 h range. Such a variety of parameters (performance lost and recovered, time scales) complicates contaminant down selection suggesting the need to develop quantitative criteria consistently applied for selection and minimize qualitatively based decisions.

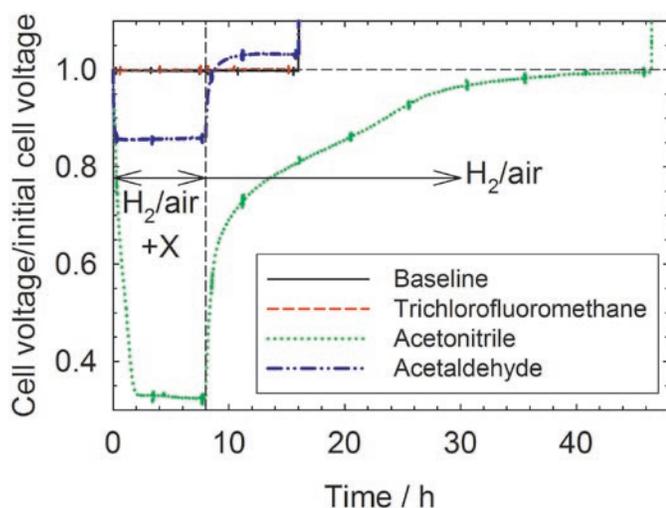

FIGURE 1. Fuel cell response resulting from a temporary contaminant X injection (20 ppm). Gore M715 membrane/electrode assembly, 25 BC SGL Technologies gas diffusion layer, 50 cm² active area, 45°C, anode/cathode, H₂/air, 10/10 kPag, 100/50% relative humidity, 2/2 stoichiometry.

Contaminants predominantly behave as illustrated in Figure 3. Upon injection of the contaminant, the cell performance drops until a steady-state is reached after a variable amount of time dependent on operating conditions. After the contamination injection is interrupted, the initial cell performance is partially, fully or supra-recovered. Points a and c correspond to the measured voltage at the time the contaminant is injected and injection is terminated. Points b and d are defined by the intersection of two asymptotes at the beginning and end of the contamination and recovery periods. Two methods were considered for contaminant ranking and rely on these four time/voltage pairs (points a to d). Method 1 relies on the combination of steady-state contamination and irrecoverable performance losses, corresponding time scales and contaminant concentration. Method 2 relies on the combination of the energy lost to contamination and regained during self-recovery:

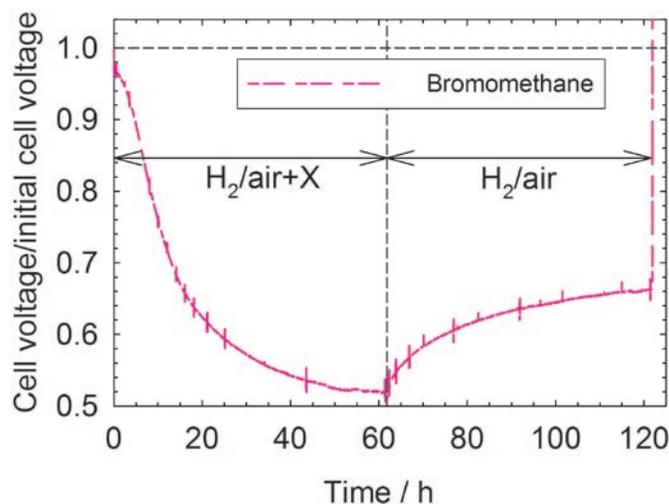

FIGURE 2. Fuel cell response resulting from a temporary contaminant X injection (50 ppm). Gore M715 membrane/electrode assembly, 25 BC SGL Technologies gas diffusion layer, 50 cm² active area, 45°C, anode/cathode, H₂/air, 10/10 kPag, 100/50% relative humidity, 2/2 stoichiometry.

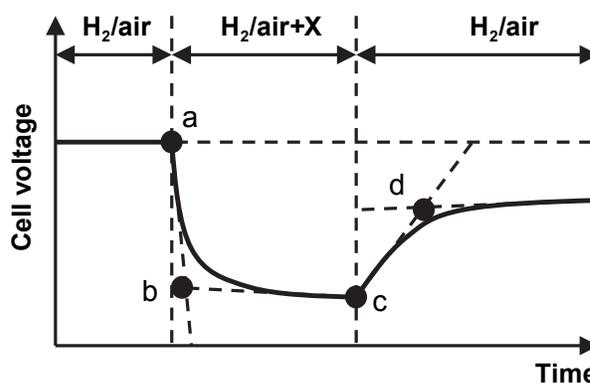

FIGURE 3. Graphical representation of the two methods parameters (points a, b, c and d) used to prioritize tested contaminants. X represents a contaminant.

$$SC_1 = \frac{(V_a - V_b)^2 (V_a - V_d)(t_d - t_c)}{c_{\text{contaminant}} (V_d - V_c)(t_b - t_a)} \quad [1]$$

$$SC_2 = \int_{t_a}^{t_b} (V_a - V) dt / \int_{t_c}^{t_d} (V - V_c) dt \quad [2]$$

where SC represents a selection criterion ($V^2 \text{ ppm}^{-1}$ or dimensionless), V_i the cell voltage at point i (V), t_i the time at point i (h), $c_{\text{contaminant}}$ the contaminant concentration in the dry reactant stream (ppm), and V the cell voltage.

Larger SC_1 and SC_2 values generally mean more significant performance losses. Table 2 shows the resulting contaminant rankings. Under wet conditions (100/50% relative humidity), the range in values is larger for SC_1 (more sensitive parameter). Only one of the top four contaminants is the same for SC_1 and SC_2 (bromomethane, italic font). For contaminants that led to a recovery exceeding the initial loss (acetaldehyde, propene), rankings (underlined font) either correspond to low SC_1 values or are scattered over the SC_2 range. Interestingly, SC_2 is not only useful to pinpoint contaminants that have a large negative effect on performance but also others that lead to a recovery exceeding the initial loss (propene). These seemingly beneficial contaminants are a good example of the envisaged use of both

selection criteria as a quantitative measure to guide decisions. A strict application of SC_1 would preclude any further interest. However, acetaldehyde and propene unusual behavior may hide some permanent performance benefit.

Conclusions and Future Directions

- Expand tier 1 airborne contaminant list with foreign cations and solids.
- Complete fuel cell contaminant screening tests (tier 1).
- Investigate the cause of the recovery exceeding the contamination performance loss (acetaldehyde, propene).
- Determine which contaminant selection criterion will be used for down selection (tier 2).
- Quantify performance loss for at least four different contaminants under various operating conditions.

Infrastructure Technologies Program Multi-Year Research, Development and Demonstration Plan:

(A) Durability

Technical Targets

This project is addressing fundamental research into effects and mechanisms of impurities on the performance and durability of polymer electrolyte membrane (PEM) fuel cell systems. The activity broadly supports the following technical targets established by DOE:

- Transportation Fuel Cells
 - Durability with cycling: 5,000 h by 2015
- Stationary PEM Fuel Cell Power Systems
 - Durability @ <10% rated power degradation: 40,000 h by 2011

FY 2011 Accomplishments

The following were the significant accomplishments during this project year:

- The degradation of Nafion[®] by radical products of H₂O₂ formed during fuel cell operation was investigated.
- The effect of Nafion[®] on Pt/C was studied and the siting of the Nafion[®] relative to the Pt identified.
- The effect of perchloroethylene on fuel cell and catalyst performance was determined using both PEM fuel cell and fundamental measurements.
- Diborane was established to be a reversible poison for fuel cell performance.

Fiscal Year (FY) 2011 Objectives

- Investigate the effect of impurities in the hydrogen fuel streams on the operation and durability of fuel cells. These impurities include water, hydrocarbons (including formaldehyde, formic acid), oxygen, inert gases (He, N₂, Ar), CO₂, CO, sulfur-containing gases, ammonia, halogenated compounds and particulates.
- Propose mechanisms for how impurities in the hydrogen fuel stream affect the components of the fuel cell catalyst and polymer membrane.
- Determine strategies to reduce the poisoning effect of these impurities.
- Disseminate findings so that they are available to other members of the DOE Hydrogen Quality team and to FreedomCAR technical teams.

Technical Barriers

This project addresses the following technical barrier from the Fuel Cells section of the Hydrogen, Fuel Cells and

Introduction

PEM fuel cells show significant potential to enable efficient, clean power for stationary and transportation applications; however, the present-day technology falls short of meeting the necessary product performance and durability requirement standards. An important limitation in the operational life of PEM fuel cells is caused by the presence of hydrogen-feed stream contaminants (e.g., ammonia, carbon monoxide, etc.). These contaminants degrade the functionality of ion exchange groups within the electrolyte, degrade catalyst activity, and result in a degradation of the overall fuel cell efficiency and operational performance.

Approach

This project is a unique combination of phenomenological studies (at Clemson University) and

fuel cell membrane electrode assembly (MEA) durability testing at SRNL, with MEAs tested at SRNL composed of the same/similar materials as being investigated at Clemson. By determining the effect of impurities on the component parts of an MEA as well as overall fuel cell performance, a comprehensive mechanism of poisoning can be proposed which should suggest means to diminish that effect. Development of an integrative model is also being undertaken by Argonne National Laboratory using the fundamental measurement results obtained by Clemson and SRNL. The fuel cell team at SRNL is integrated into the U.S. Fuel Cell Council Joint Hydrogen Quality Task Force, presently engaged to address the International Organization for Standardization Technical Committee 197: Hydrogen Fuel – Product Specification: Proton exchange membrane (PEM) fuel cell application for road vehicles.

Results

During PEM fuel cell operation, formation of H_2O_2 and material corrosion occurs, generating trace amounts of metal cations (i.e., Fe^{2+} , Pt^{2+}) and subsequently initiating the deterioration of cell components and, in particular, PFSA membranes (e.g., Nafion[®]). In a study at Clemson, a quantitative examination of properties and conductivities of degraded Nafion[®] membranes at conditions relevant to fuel cell environments (30-100 % relative humidity [RH] and 80°C) was performed. The degradation degree (defined as: loss of ion-exchange capacity, weight, and fluoride content), water uptake, and conductivity of H_2O_2 -exposed membranes were found to strongly depend on Fe content and H_2O_2 treatment time (see Figure 1). Fourier transform infrared (FT-IR) analysis revealed that Nafion[®] degradation preferentially proceeds at the sulfonic end group and at the ether linkage located in the pendant side chain and that the H-bonding of water is weakened after prolonged H_2O_2 exposure.

Results from an investigation at Clemson established a more fundamental understanding of the effect of humidity on CO poisoning of Pt/C at typical fuel cell conditions (80°C, 2 atm). The presence of water vapor decreased the rate of CO adsorption on Pt, but had very little effect on the resulting CO surface coverage on Pt_s (θ_{CO}) at steady-state. The steady-state θ_{CO} 's at 80°C for Pt exposed to H_2 ($P_{\text{H}_2} = 1$ atm) and a mixture of $\text{H}_2/\text{H}_2\text{O}$ (1 atm H_2 , 10%RH) were 0.70 and 0.66 ML, respectively. Furthermore, total strongly-bound surface hydrogen measured after exposure to $\text{H}_2/\text{H}_2\text{O}$ was, surprisingly, the sum of the exchangeable surface hydrogen contributed by each component, even in the presence of CO.

An exploration of the effect and siting (location) of Nafion[®] on Pt/C as exists in a PEM fuel cell catalyst layer was carried out.

Surprisingly, the presence of 30 wt% Nafion[®] appears to have only a minimal effect on the adsorption capability of either hydrogen or CO on Pt. Experimental and modeling results of cyclopropane hydrogenolysis in an idealized pore suggest that partial blockage of only the pore openings by the Nafion[®] for the meso-macropores is sufficient to induce diffusion limitations on the reaction. The facts suggest that most of the Pt particles are in the meso-macropores of the C support, whereas Nafion[®] is present primarily on the external surface of the C where it blocks the micropores but only partially the pore mouths of the meso-macropores.

PCE was chosen as a model compound for chlorinated cleaning and degreasing agents that may be introduced into a fuel cell as contaminants at a fueling station and/or during vehicle maintenance. During this year SRNL completed fuel cell studies using PCE. Figure 2a shows the results of the PCE concentration detected by Fourier transform infrared at different points in the fuel cell. The spectrum of gaseous PCE has three main peaks in the region between 700 and 1,000 cm^{-1} . From this spectrum, the strong peak at 915 cm^{-1} (see insert of Figure 2a) was used to monitor the PCE. Accordingly, a concentration of 164 ppm of PCE was injected at the anode inlet. However, a substantial reduction

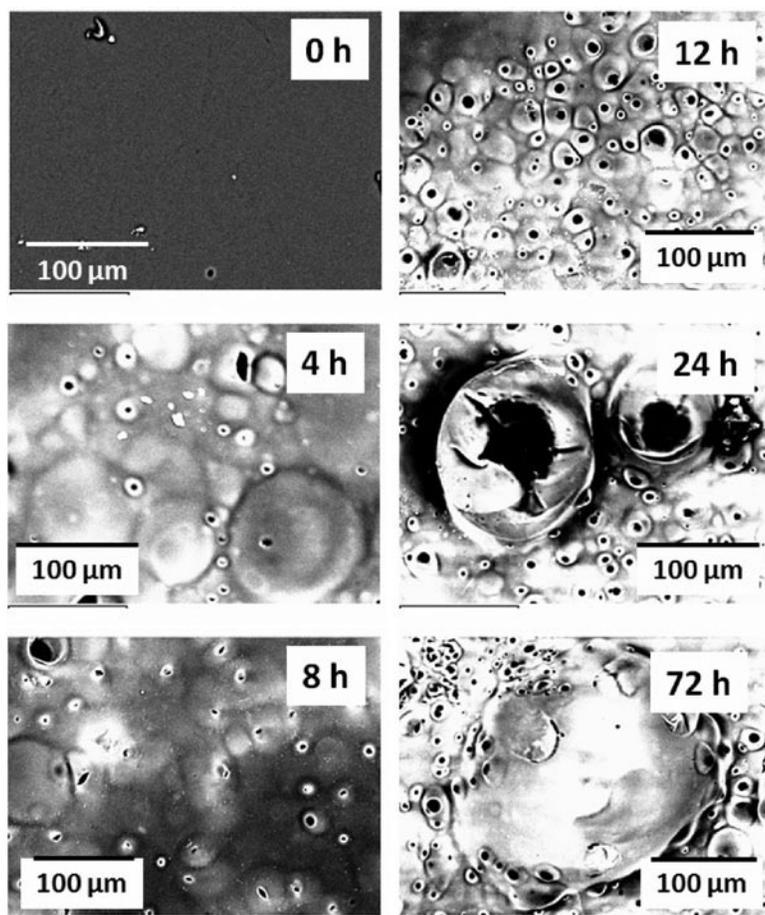

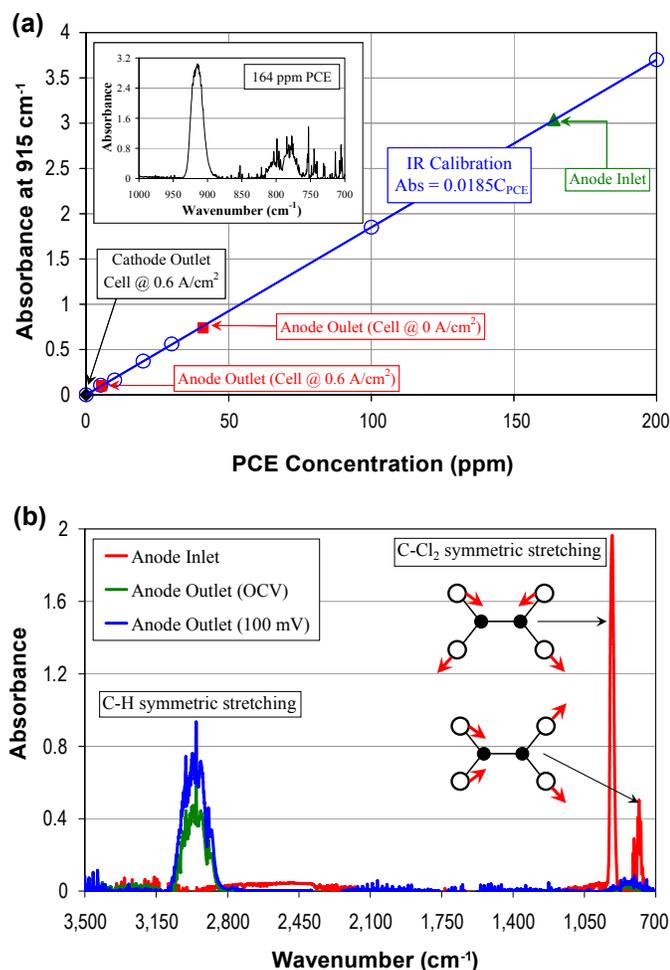

FIGURE 1. Scanning electron microscope images of the surface of a M90 membrane (10% of the H^+ in Nafion replaced by Fe^{2+}) after various times of H_2O_2 treatment.

OCV - open circuit voltage

FIGURE 2. (a) FT-IR calibration and concentration detected during fuel cell operation for PCE using the absorbance band at 915 cm^{-1} of the PCE gas phase spectrum (figure insert). (b) FT-IR absorbance spectra of the decomposition products during fuel cell operation with PCE poisoning.

to 41 ppm was detected at the anode outlet during open circuit. Moreover, after a current of 0.6 A/cm^2 was applied to the cell, the PCE concentration was further reduced to 5.4 ppm. No PCE was detected at the cathode outlet during any of the tests. Figure 2b shows peak transformation from when the spectra were measured at the inlet of the fuel cell and at the outlet with and without a voltage applied. At the exit after the PCE-containing stream had flowed through the catalyst layer, the C-Cl_2 spectrum disappeared and a carbon-hydrogen symmetric stretching was observed. This result indicates the de-chlorination of PCE.

At Clemson, the poisoning effect of PCE on the activity of a Pt fuel cell catalyst for the adsorption and activation of H_2 was investigated at 60°C and 2 atm using hydrogen surface concentration measurements. In the presence of only H_2 , introduction of up to 540 ppm PCE in H_2 to Pt/C resulted in a reduction of available Pt surface atoms (measured by H_2 uptake) by ca. 30% but not enough

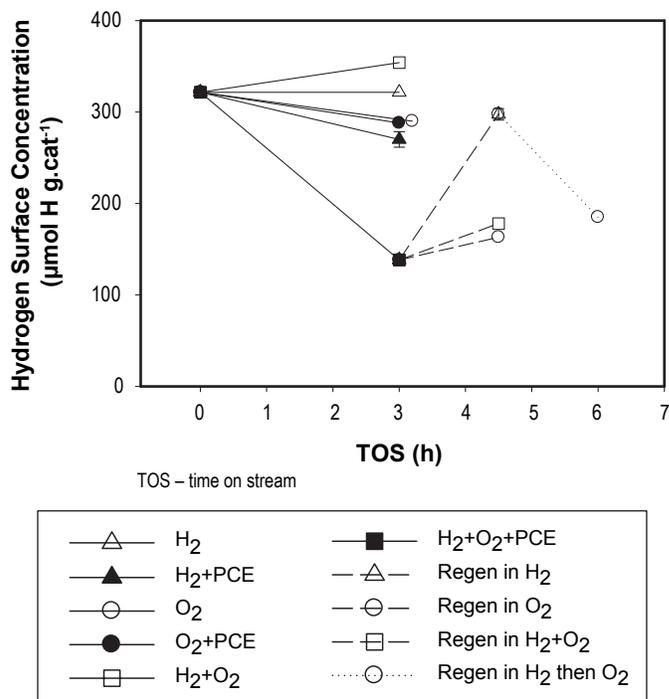

FIGURE 3. Comparison of exposure and poisoning by 150 ppm PCE of Pt/C in different gases (H_2 , O_2 , and $\text{H}_2 + \text{O}_2$) (solid and dotted lines). Effect of different regeneration gases (dashed lines).

to shift the H_2 - D_2 exchange reaction away from being equilibrium limited. Exposure of Pt/C to PCE in a mixed redox environment (hydrogen+oxygen), similar to that at the cathode of a fuel cell, resulted in a much more significant loss of Pt surface atom availability, suggesting a role of oxygen in PCE decomposition and/or Cl poisoning (see Figure 3). Regeneration of the catalyst activity of poisoned Pt/C showed the highest level of recovery when regeneration was carried out in only H_2 , with much less recovery in $\text{H}_2 + \text{O}_2$ or O_2 . The results from this study are in good agreement with those found in the fuel cell study at SRNL.

Diborane (DB) was studied as a model molecule representative of hydrogen storage boron compounds. While no effects were observed on the ionic conductivity and during cyclic voltammetry, a large effect on fuel cell performance was observed as indicated in the potentiostatic curve for a Gore MEA in Figure 4a. There was a drop in performance of about 39% for a concentration of 50 ppm of DB. While the effects seem to be severe, the cell recovers as soon as the DB is removed from the stream. Figure 4b shows the polarization before, during and after recovery from the DB poisoning. The figure indicates that the loss in performance arises mostly from the kinetic limited section (voltage drop in the low current area). However, no indication of catalyst poisoning is observed during cyclic voltammetry. After the DB poisoning is discontinued, the fuel cell performance recovers to approximately 100%.

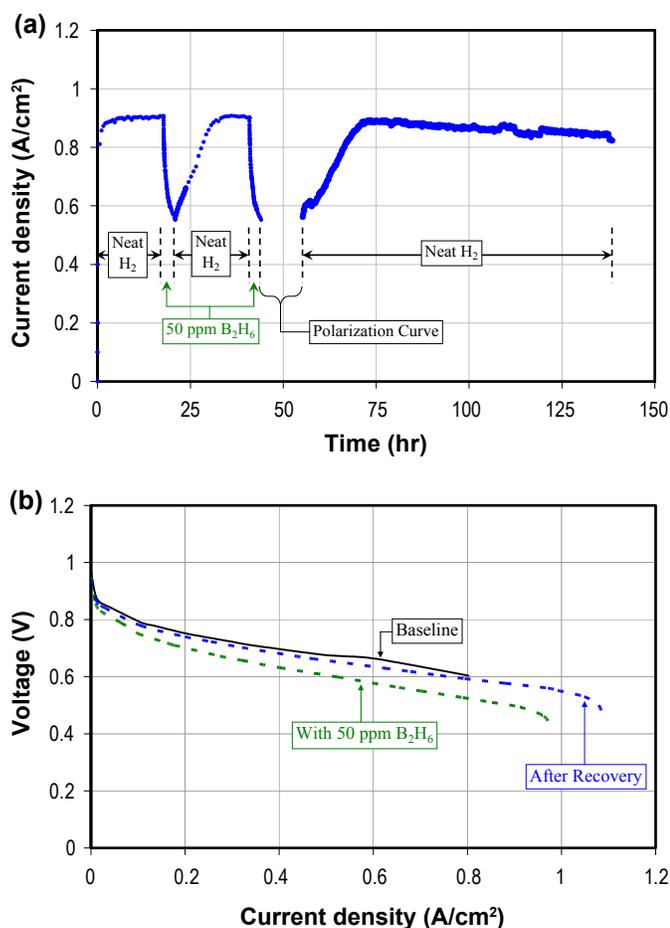

FIGURE 4. (a) Potentiostatic (0.6 V vs. DHE) and (b) polarization scan before, during exposure to 50 ppm of diborane in the hydrogen stream, and after recovery of a fuel cell with a 50 cm² Gore MEA having an anode Pt loading of 0.1 mg/cm² and operated at 60°C and 50% RH.

Conclusions and Mitigation Strategies

- The presence of trace amounts of Fe₂₊ was found to cause significant-severe degradation of Nafion[®] by H₂O₂ formed during fuel cell operation, with degradation preferentially proceeding at the sulfonic end group and at the ether linkage located in the pendant side chain of the Nafion[®].
 - An investigation of Nafion[®] on Pt/C determined that Nafion[®] has little/no effect on the Pt catalyst in the catalyst layer, even though it comprises 30 wt% of that layer. Experimental results and modeling suggest that most of the Pt particles are in the meso-macropores of the C support, whereas Nafion[®] is present primarily on the external surface of the C where it blocks significantly the micropores but only partially blocks the pore mouths of the meso-macropores.
 - The presence of water vapor was found to decrease the rate of CO adsorption on Pt, but had very little effect on the resulting CO surface coverage of PtS (qCO) at steady-state (0.66 vs. 0.70 ML in absence of water vapor).
 - PEM fuel cell studies of the effects of perchloroethylene (PCE) found that the loss in performance arises from the dechlorination of PCE and affects most likely the cathode electrode.
 - Exposure of Pt/C to 150 ppm PCE in a mixed redox environment (hydrogen+oxygen), similar to that at the cathode of a fuel cell, resulted in a much more significant loss of Pt surface atom availability (57% loss) than in hydrogen (15%) or oxygen (11%) alone, suggesting a role of oxygen in PCE poisoning of Pt.
 - Regeneration of catalyst activity of PCE poisoned Pt/C showed the highest level of recovery when regeneration used only H₂, with much less recovery in H₂+O₂ or O₂.
 - Diborane (B₂H₆, DB), a model impurity from hydrogen storage boron compounds, was found to cause a 39% loss in fuel cell performance. However, full recovery was attainable once diborane was removed from the fuel stream.
- Based on the results from this year, the following impurity mitigation strategies can be proposed:
- It is critical to minimize contamination of Nafion[®] with transition metal ions since they (and especially Fe²⁺) catalyze the degradation of Nafion[®] by radical products of H₂O₂ formed during fuel cell operation.
 - Higher humidity lessens the degree of degradation of Nafion[®] conductivity by radical products of H₂O₂.
 - Water vapor does not appear to affect CO poisoning of Pt. Therefore, use of higher or lower humidity would appear not to be a factor in improving resistance to CO poisoning.
 - Chlorinated compounds should be minimized as contaminants in either the oxygen or hydrogen streams, even though poisoning of the Pt requires the presence of oxygen and takes place apparently at the cathode. Poisoning Cl species can be transported from the anode to the cathode.
 - Pt catalysts poisoned by Cl appear to be able to be regenerated by H₂. However, re-exposure of the catalyst to any oxygen even in the absence of PCE in the gas streams results in renewed poisoning of the catalyst.
 - DB should be minimized in the hydrogen fuel stream as ppm levels result in significant poisoning of the fuel cell. However, this effect appears to be totally reversible once the DB is removed from the fuel stream.

Project Start Date: October, 2007

Project End Date: March, 2011

Fiscal Year (FY) 2011 Objectives

- Investigate effects of impurities on catalysts, membranes and other fuel cell (FC) components.
- Understand the effect of catalyst loadings on impurity tolerance.
- Investigate the impacts of impurities on catalyst durability.
- Develop methods to mitigate negative effects of impurities.
- Develop models of fuel cell-impurity interactions.
- Determine impurity tolerance limits in view of the technical targets for catalyst loading, performance and durability.
- Provide experimental data to hydrogen suppliers for defining fuel specifications.

Technical Barriers

- (B) Cost: the cost of fuel cells limits their use:
- Fuel and air impurity removal systems increase cost, weight and complexity.
 - Higher Pt loading required for maintaining performance, in the presence of impurities, increases cost.
- (A) Durability: durability may decrease in the presence of impurities.
- (C) Performance: fuel cell performance is degraded by impurity effects.

Technical Targets

The technical targets for catalyst loading are indicated in Table 1. These targets were formulated with the assumption that FC performance will not be degraded by fuel and/or air impurities or contaminants. One of the specific goals of this project is the experimental determination of the limits of impurity tolerance within those technical targets. The results of this project will provide data for defining the FC hydrogen fuel specifications and intake air quality and assess the role of impurities in fuel cell performance degradation.

FY 2011 Accomplishments

- Effect of 100 ppb SO₂ in air on 0.1 mg/cm² Pt loading cathode fuel cell performance testing completed (*milestone*).
- Effect of 100 ppb SO₂ in air on 0.2 mg/cm² Pt loading cathode fuel cell long term (500 hr) performance testing completed (*milestone*).
- NO₂ fuel cell poisoning effect was shown to occur via hydrogen reduction of oxides of nitrogen (NO_x) to ammonia.
- Effect of 5 ppm NO₂ in air on 0.2 mg/cm² Pt loading cathode fuel cell long term (500 hr) performance testing completed (*milestone*).
- Iridium oxide solid-state pH sensors were used to determine changes in local proton activity in cation-poisoned, polymer membrane fuel cell electrodes.

Introduction

Fuel cells efficiently convert flows of chemical fuel and oxygen to electrical power. Fuel cell performance may be severely impacted by contaminants or impurities that decrease the electrochemical catalytic rates, interfere with proton transport across the polymer electrolyte, or impede the flow of reactants to/or reaction products away from the

anode or cathode charge transfer interfaces. The impurities may be generated by the fuel synthesis process or be present as ambient air impurities. The platinum metal catalyst surfaces may be deactivated by strongly adsorbing species such as sulfur containing molecules and carbon monoxide. The strongly bound species both block surface sites for catalytic activation and alter the electronic structure of the surface decreasing charge transfer rates. Positively charged contaminant ions often times have much greater chemical affinity to the ion transport sites within the polymer than protons. The foreign cations typically have lower mobilities than protons and reduce ionic conductivity. The presence of impurities may also decrease the operational lifetime of the fuel cell by decreasing performance irreversibly to an unacceptable value or by increasing component failure rate.

Approach

Our approach to understanding impurity interactions with fuel cell components utilizes both experimental and modeling efforts. We carry out fuel cell performance measurements in the presence of known quantities of introduced impurities and then study the impurity interactions with fuel cell components using electrochemical diagnostic methods such as adsorbate stripping voltammetry and alternating current impedance spectroscopy. Sometimes the experiments are performed in neutron imaging systems to visualize the effect of the impurity upon the water content and transport properties of fuel cell components. Post-experimental analysis includes trace level chemical analysis of fuel cell components and effluent water, electron microscopy and X-ray diffraction of the solid materials. We also experimentally determine impurity thermodynamic behavior (ion-exchange, proton and water activity coefficients) and transport properties such as membrane permeability and ionic conductivity.

Theoretical studies include computer models of impurity interactions with anode and cathode electrocatalysis. We also model the effects of foreign cations upon fuel cell performance. The modeling results are validated with experimental measurements such as hydrogen pump experiments and X-ray and electron beam microscopy of impurity distribution.

Results

The most prevalent sulfur containing air species is sulfur dioxide from fossil fuel combustion. The DOE future targets call for a decrease in anode and cathode Pt loading. Last year we evaluated the response of two 50 cm² fuel cells: a LANL-prepared Nafion[®] 212 fuel cell and a commercial fuel cell membrane with an anode/cathode loading: 0.1/0.2 mg Pt/cm², to 100 ppb SO₂ in air (2.0 stoichiometry) injection at the cathode inlet past the humidification system (100% saturation). The fuel cell tests were performed at constant current 1 A/cm² for 500 hr. The fuel cell operating voltages at constant current decreased rapidly with approximately

200 mV of loss for both cells after sulfur dioxide injection was terminated. This year we evaluated the effect of lowering the cathode loading to 0.1 mg Pt/cm². A loss of ~200 mV of fuel cell voltage was also observed for the 1 A/cm² constant current experiment. Sulfur dioxide tolerance still remains a key issue in the widespread deployment of fuel cells in areas of poor air quality.

NO_x, from fossil fuel combustion systems, also pose a potential threat to fuel cell performance. High combustion temperatures and pressures promote the reaction of nitrogen with air to form these acid gases. We have studied, by cathode injection, the long term effects of 5 ppm nitrogen dioxide, into an operating fuel cell similar to the one used for the sulfur dioxide experiments. Our experiments last year indicated that NO₂ reduces the fuel cell voltage by ~150 mV but reaches steady-state after about 50 hours of operation. We previously hypothesized that the NO₂ is probably being reduced by hydrogen to ammonium cations; this year we detected, using infrared spectroscopy, the presence of ammonium ions in nitric oxide contaminated fuel cell assemblies.

We have continued the effort to develop iridium oxide-based pH sensors and test their viability as local probes of the effects of cationic impurities in perfluorosulfonic acid polymers on oxygen reduction. Due to the electroneutrality condition, the impurities stoichiometrically replace hydrated protons (H⁺_{aq}) in Nafion[®] and the associated pH changes can be used to monitor local concentrations of the impurities.

The effort has focused on sensors fabricated by the chemical oxidation of pure iridium metal in molten lithium carbonate at 790°C. Such sensors have better mechanical properties than the sensors obtained by the electrochemical deposition of iridium oxide onto metallic substrates and are also less sensitive to interferences from red-ox agents. We tested the sensors using pure and partially neutralized Nafion[®], containing 40%, 60%, and 90% of Cs⁺. The testing was performed in pure oxygen atmosphere at three temperatures (20, 40 and 60°C) and 100% relative humidity.

As the time necessary to attain equilibrium in the polymer electrolyte was longer than that in liquid electrolytes and the measured potential was frequently unstable for long periods of time, we tentatively assumed that the potential reached its equilibrium value, when its drift did not exceed 1 mV hr⁻¹. The process of equilibration could be accelerated by short time excursions to higher temperatures (60°C), after which the measured potentials were reversible to temperature changes but stable (<1 mV hr⁻¹) at a constant temperature (Figure 1). However, the behavior such as that shown in Figure 1 was observed only for pure and 90% Cs-doped Nafion[®]. The potentials of Ir/IrO_x sensors comprising pure Nafion[®] and equilibrated in the above way were found to be sensitive to gaseous ammonia contamination (Figure 2).

The potentials of Ir/IrO_x sensors in Nafion[®] partially (40% and 60%) doped with Cs⁺ exhibited an erratic

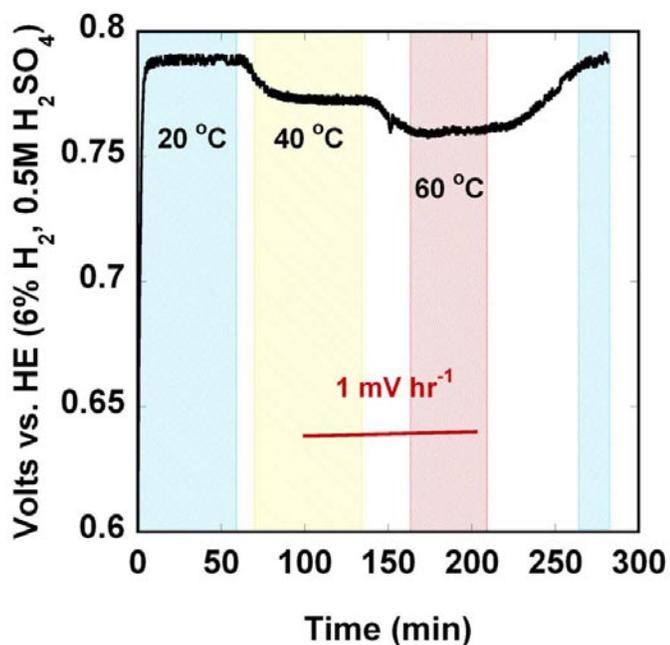

FIGURE 1. Measured potential of a Ir/IrO_x sensor in pure Nafion® at 100% relative humidity and different temperatures. Temperature: 20°C (blue), 40°C (yellow), 60°C (red), variable (no color).

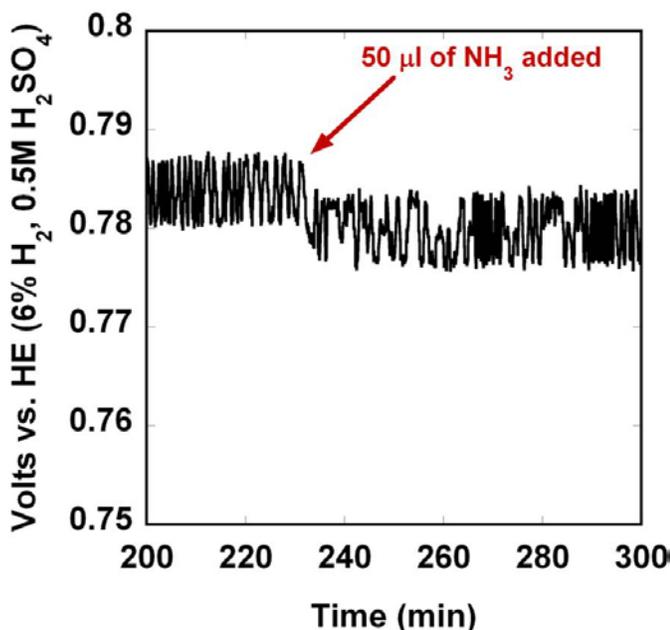

FIGURE 2. Effect of ammonia on the potential of a Ir/IrO_x sensor embedded in pure Nafion®. The experimental chamber had a volume of ~200 cm³. 50 µl of 25% NH₃ solution was added to ~10 cm³ of deionized water on the bottom of the chamber. Temperature 20°C, relative humidity 100%.

behavior. No stable potentials could be measured at all selected temperatures. Moreover, temperature increase invariably led to a very quick decrease of the measured potential that significantly exceeded ~1 mV/°C decrease observed for pure (Figure 1) or 90% neutralized Nafion®. The behavior could not be linked to any sensor failure, such as iridium oxide or Nafion® delamination, water condensation, loss of electrical contact, etc., and consequently it is believed to originate from an actual drop in H⁺_{aq} concentration (pH increase) at the IrO_x/Nafion® boundary. The drop in H⁺_{aq} concentration may result from either the interface becoming preferentially occupied by the hydrophobic (backbone) component of Nafion® [1,2] or by Cs-populated ionic component of Nafion® at elevated temperatures. Both options can be linked to temperature induced nanophase transitions in partially doped Nafion®. As the transitions are visible only when Nafion® is nearly half neutralized (40% and 60%) with Cs, the second option seems more likely, i.e., that weaker hydrated Cs⁺ rather than H⁺ tend to occupy the interface at elevated temperatures. The conclusion is supported by X-ray radiography, which demonstrates virtually no ion exchange, i.e., persistent phase separation at the boundary between pure Nafion® and Nafion® ~100% neutralized with Cs. Irrespective of the above interpretation of the data, the results indicate that the unfavorable effect of cationic impurities on the oxidation reduction reaction through the lowering of H⁺_{aq} concentration and water activity at the fuel cell cathode may be additionally amplified by the unfavorable phase separation phenomena.

Conclusions and Future Directions

Gas phase and cation impurities were demonstrated to decrease fuel cell performance. The mechanisms include: catalyst poisoning, cation ion exchange and a reduction in the local proton concentration near the electroactive cathode interface.

Fiscal Year (FY) 2011 Objectives

- To develop a new proton exchange membrane (PEM) with higher proton conductivity and improved durability under hotter and drier conditions, in order to meet DOE Hydrogen, Fuel Cells and Infrastructure Technologies Multi-Year Research, Development and Demonstration Plan 2010/2015 commercialization targets for automotive fuel cells.
- Test new membrane in fuel cell membrane electrode assemblies.

Technical Barriers

This project addresses the following technical barriers from the Fuel Cells section of the Fuel Cell Technologies Program Multi-Year Research, Development and Demonstration Plan:

FY 2011 Accomplishments

- We have developed a new PEM for PEM fuel cells. This new membrane comprises a new multi-acid side-chain (MASC) ionomer, stabilizing additives for improved chemical stability and polymer nanofibers for improved mechanical stability.
- In out-of-cell tests this new membrane has shown superior mechanical stability, chemical stability and conductivity compared other available membranes. It has met DOE 2015 targets for conductivity and other physical properties, except for the conductivity under the most aggressive condition, 120°C, 40 kPa H₂O (about 25% RH at 1 atm).
- Membrane electrode assemblies (MEAs) with this new membrane provide increased performance, lower cell resistance and have met all DOE 2015 durability targets (Table 1).

Introduction

Proton exchange membrane fuel cells (PEMFCs) represent a promising power source for a variety of applications. While many breakthroughs have been made over the last few years in the development of PEMFCs, technical and economic barriers for their commercialization still exist. Key areas where improvements are still needed are in expanding the temperature range and lowering the humidification requirements of the stack [1]. Requirements of system size, efficiency, performance, start-up and cooling mean that fuel cells must be able to run robustly and exhibit adequate durability under a wide variety of operating temperatures, including temperatures up to 120°C. They must also be able to do this with little or no external gas humidification (i.e., “dry”), and during start-up, shut-down, or periods of lower stack temperatures, they must run in the presence of, and be stable to, some liquid water in the gas channels. Unfortunately, operation under these hot, dry conditions seriously compromises both the conductivity and durability of the ionomer membrane. The objectives of this collaborative effort are to develop new PEMs for fuel cells capable of providing excellent durability and performance while operating under low humidification conditions and at temperatures ranging from -20°C to 120°C.

Approach

The focus of this project is to develop a new proton exchange membrane which can operate under hotter, drier conditions than the state-of-the-art membranes today. These membranes and MEAs made from them should meet the performance and durability requirements that meet 2010 DOE technical targets for membranes. Activities include:

- Synthesize and test new polymer membranes, including both fluorinated and non-fluorinated polymers as well as composite or hybrid systems, and evaluate their conductivity and chemical and mechanical stability.
- Evaluate new membrane manufacturing methods for increasing membrane mechanical properties and improving MEA lifetime.
- Develop new membrane additives aimed at increasing conductivity and improving membrane stability/durability under these dry conditions.
- Perform both experimental and theoretical studies of factors controlling proton transport and mechanisms of polymer degradation and factors affecting membrane durability in an MEA.
- Focus on materials which can be made using processes which will be scalable to commercial volumes using cost-effective methods that can meet the industry target.

Results

In the course of this four-year project we developed a new PEM with improved proton conductivity, chemical

stability and mechanical stability. We incorporated this new membrane into MEAs and evaluated performance and durability. The development of this new membrane involved synthesizing and evaluating new ion-containing polymers, new stabilizing additives and polymer nanofibers for mechanical stabilization. Process development work included developing and/or optimizing methods of making stable dispersions with ionomers and additives as well as coating and post processing nanofiber stabilized membranes. MEA constructions were optimized to allow effective evaluation of the membrane performance and durability in a fuel cell.

In the past we have shown that lower EW ionomers, based on our 3M perfluorinated sulfonic acid (Figure 1, PFSA), provide higher proton conductivity under drier conditions. PFSA membranes with EW under about 700 can meet DOE conductivity targets [2]. Unfortunately, the mechanical integrity of these low EW membranes is poor. The 3M ionomer swells excessively at EWs below about 750 and becomes soluble in boiling water at EWs below about 650-700. At an EW of 700 the tetrafluoroethylene (TFE) segments in the polymer backbone are short, and the crystallinity index, measured by wide angle X-ray scattering is nearly zero. Even lower EW, non-soluble membranes (i.e. 700 EW) swell excessively. Figure 2 shows that membranes prepared from ionomers with EWs above about 750 show a gradual increase in hydration in boiling water with decreasing EW, increasing from about 14 moles of water per sulfonic acid group ($\lambda=14$) for an EW of 1100, to about 33 waters of hydration per sulfonic acid group ($\lambda=33$) for an EW of 750. Below this EW water absorption increases dramatically. The 700 EW ionomer has a λ value of >100 . Membranes from ionomers with EWs lower than this partially dissolve in boiling water so this test can not be performed [3]. This excessive swelling or membrane solubility is known to lower MEA durability during fuel cell operation [4]. One way to produce polymers with long enough TFE segments in the backbone for crystallization and low enough EW to provide high conductivity is to have more than one protogenic hydrogen on each functional side-chain [5]. Towards this end, we have used the bis sulfonyl imide acid as a protogenic group and linking moiety to prepare several MASC ionomers, some of which are shown in Figure 1. The bis sulfonyl imide acid is highly acidic, in some cases more acidic than a structurally similar sulfonic acid [6]. Fuel cell membranes from polymers containing this functional group have been prepared in the past through the polymerization of imide functional monomers with TFE [7]. We have prepared low EW ionomers starting sulfonyl fluoride polymers which have EWs high enough to provide sufficient backbone crystallinity in the resulting ionomer to control swelling. Swelling data for examples of low EW ionomer prepared by this method are shown in Figure 2. Membrane samples prepared from both the ionomer labeled Ortho Bis Acid and PFIA absorb about 40 waters per acid group, much lower than the 700 EW PFSA. We have prepared samples of the 625 EW PFIA with in-plane linear swelling as low as 20%, similar to what we see for 825 EW

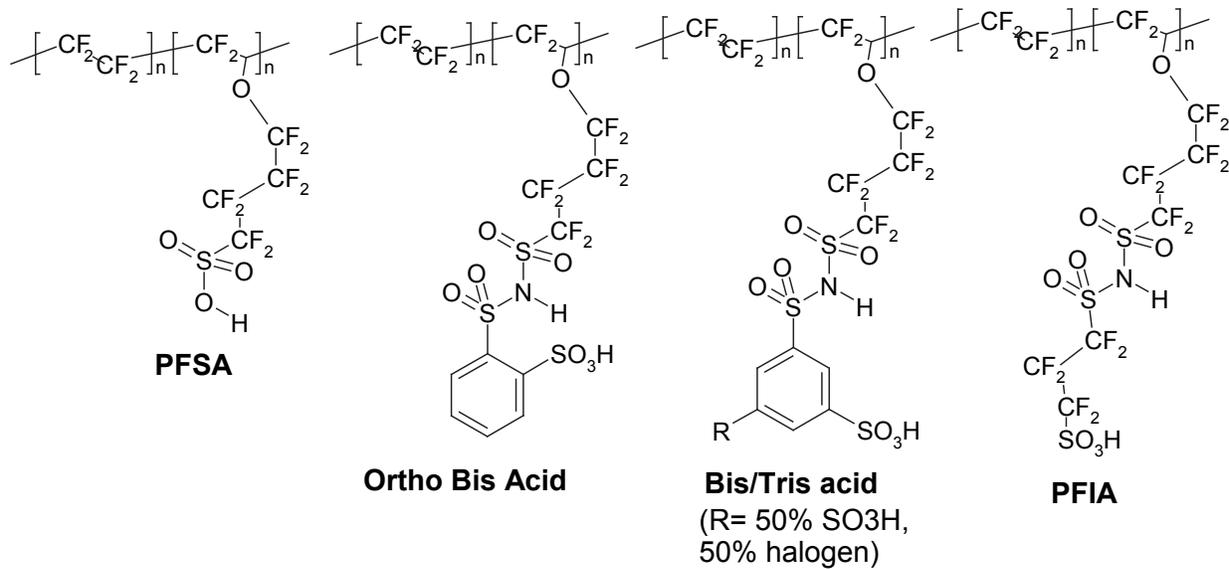

FIGURE 1. Structure of Selected Ionomers Based on the 3M Ionomer Backbone

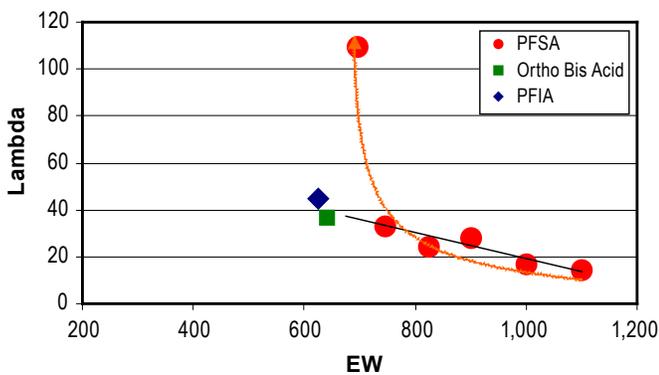

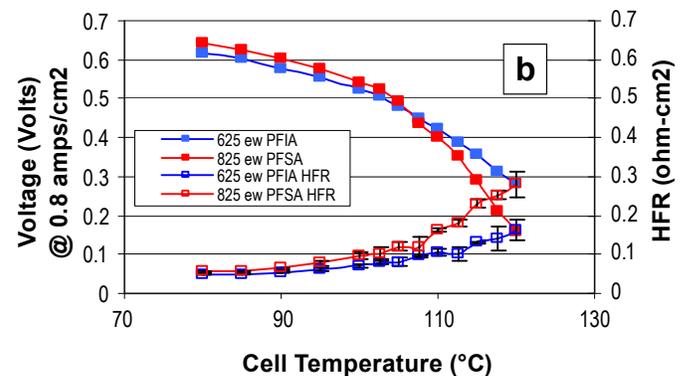

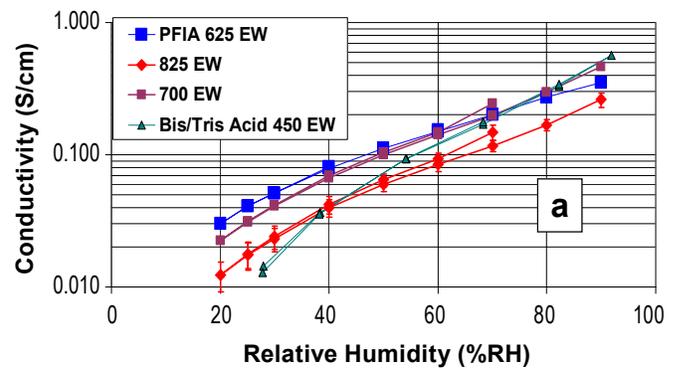

FIGURE 2. Water Absorption in Boiling Water as a Function of EW (Absorption is given as lambda (λ), or the number of water molecules per acid group.)

membranes which have provided up to 18,000 hours in accelerated durability tests in 50 cm² MEAs [2].

The ionomer selected for the final evaluation and testing is a 625 EW PFIA ionomer membrane (Figure 3). This membrane is reinforced with polymer nanofibers and also comprised a stabilizing additive package described in previous reports. The durability improvements that this additive package provides, including providing MEAs which lasted up to 18,000 hours in our accelerated durability test, were presented at the 2009 and 2010 Annual Merit Review meetings. A micrograph of the nanofiber reinforced membrane is shown in Figure 4. MEAs prepared from this membrane have also lasted over 2,300 hours in the chemical durability (OCV) test and over 20,000 cycles in the mechanical durability (RH Cycle) test (Table 1) [8]. Based

HFR - high-frequency resistance

FIGURE 3. a) The conductivity at 80°C for selected ionomer membranes. Conductivity was measured using a 4-point, in-plane conductivity cell inside a constant humidity oven. b) The voltage of two 50 cm² MEAs with an 825 EW PFSA and a 625 EW PFIA membrane at 0.8 A/cm² running on H₂/air at ambient pressure. The cell inlet humidification is held constant with an 80°C dew point and the cell temperature is raised from 80°C to 120°C. This causes the relative humidity to drop from 100% to about 24%.

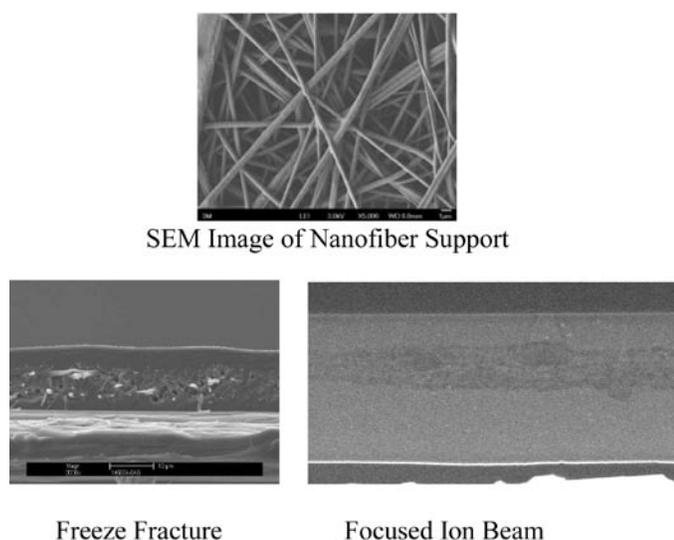

FIGURE 4. Scanning electrode micrographs (SEMs) of the nanofibers and cross-sections showing similar membranes with nanofiber support. Samples were prepared while still on carrier liner (bottom layer in images).

on this and other testing, we down-selected the PFIA as the ionomer which was used in the remainder of this project and focused on further improvements in the chemical and mechanical durability of membranes made from this ionomer to allow them to meet these durability requirements. During the course of this year we have also developed and optimized electrode and MEA construction. We have evaluated different ionomer equivalent weights, ionomer to carbon ratios, catalyst types, gas diffusion layer types, and process variables. Test methods were developed that screened electrodes over a variety of test conditions to optimize performance over the whole range of automotive operating conditions – cool/wet to hot/dry and high current. Results of that work led to gains in performance and a reduction of catalyst loadings 38% over the initial baseline. Gains were also realized in catalyst cycling stability and in the reduction of the overall MEA fluoride release rate. New processing methods and catalyst morphologies provided further gains in both performance and catalyst stability. A summary of performance and durability data collected, including data from the FreedomCAR & Fuel Partnership Fuel Cell Tech Team Cell Component Accelerated Stress Test Protocols for PEM Fuel Cell Membranes, is shown in Table 1 [9].

Conclusions and Future Directions

This project ended March 31, 2011. As stated above, we developed a new ionomer membrane with improved performance and durability. Going forward we intend to build on this new technology to gain further understanding of the factors influencing conductivity and durability in this membranes and develop new materials based on this understanding.

Fiscal Year (FY) 2011 Objectives

- Demonstrate 20,000 relative humidity (RH) cycles in a 1 mil membrane.
- Manufacture larger, more consistent membranes.
- Manufacture supported membranes that are thinner than 1 mil.
- Utilize lower equivalent weight (EW) ionomers in thin supports.

Technical Barriers

This project addresses the following technical barriers from the Fuel Cells section (3.4.4) of the Fuel Cell Technologies Program Multi-Year Research, Development and Demonstration Plan:

- Durability
- Cost
- Performance

FY 2011 Accomplishments

- Demonstrated 20,000 RH cycles in a 1 mil membrane.
 - Membrane had higher in-plane conductivity than NRE211.
 - Stopped test at 20,000 cycles.
- Manufactured larger membranes.
 - Numerous samples sent to a third party for testing.
- Greatly decreased chemical degradation under open circuit voltage testing.
 - Greater than an order of magnitude reduction.
 - Testing confirmed by a third party for testing.
- Both commercially available polyethersulfone (PES) and ultra-high molecular weight polyethylene (UPE) successfully incorporated as porous supports in 3DSM:
 - Swelling reduction similar to 2DSM.
 - Conductivity penalty of support ~33%.

Introduction

PFSA materials have demonstrated promising high temperature/low RH conductivity, yet are still unsuitable for automotive applications. Increasing acid content and making the membranes thinner are two methods for lowering the resistance of these materials. However, each of these methods adversely affects mechanical durability of the membrane. GES is combining the good conductivity properties of high acid content PFSA and improve their mechanical properties by making composite materials.

Approach

GES's approach is to use very high acid content PFSA materials and support them with high-strength non-acidic materials. This involves using commercially available PFSA materials as well as generating new PFSA polymers, generating the supports, and finally forming and characterizing the composites.

Results

GES has successfully imbedded high acid content PFSA materials in laser-drilled supports consisting of either polysulfone or polyimide (Kapton). Figure 1 shows the laser-drilled support, as well as the composite DSM. A matrix of support material, pore size, support thickness and EW of PFSA fill has been completed. When the supports are 10% of the total material and have no greater than 60% void space, they nearly eliminate swelling in the x-y direction. This is true regardless of hole size, acid content of the PFSA fill material, or whether polysulfone or polyimide was used as the support. Fuel cell testing has been carried out on a 2-mil (50 micron) DSM membrane consisting of a 1/3-mil (8 micron) polyimide support filled with 700 EW PFSA and the 2DSM far outperforms Nafion® 112 performance.

A sample composite material with low EW PFSA and 10% support material has demonstrated 2-3 times the conductivity of Nafion® 112, the PFSA standard, over the entire range of RH as shown in Figure 2. This conductivity

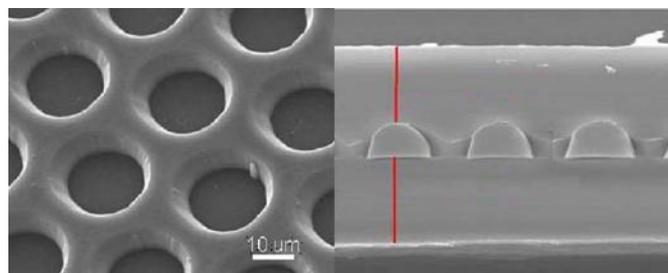

FIGURE 1. Scanning Electron Microscope Images of Laser-Drilled DSM Support (left, top view) and Support Filled with PFSA (right, cross section)

still falls short of the DOE target however, as seen in the figure. Previously it appeared that this approach would not be able to reach the DOE's cost target, however in a separate DOE contract GES has demonstrated a successful method of micro-molding these substrates.

Commercially available porous supports offered an alternative to the cost-prohibitive 2DSM supports: an unforeseen development from the original proposal but very promising as the 3DSMs demonstrated the dimensional stability and improved mechanical properties of the 2DSM. We successfully incorporated both 1100 EW and 830 EW PFSA ionomers into commercially available PES and UPE and tested the membranes under electrolysis conditions. In Figure 3, the electrolysis performance of a 3 mil (75 micron) 3DSM prepared with 830 EW ionomer and UPE support is compared to the 1100 EW electrolysis membrane electrode assembly with comparable thickness. Electrolysis conditions were used as the poor membrane-electrode interface in fuel cell membranes contributes to the overall resistance and thereby decreases fuel cell performance. Electrolyzer testing allows us to test the membranes in an electrochemical cell and determine the performance penalty due to the support, even with a thick membrane. The thinnest PES porous support commercially available is 4 mils (100 micron) thick. We are currently working with Millipore on thinner supports, and they have supplied us with 1- and 2-mil-thick (25 and 50 micron) UPE and 3-mil (75 micron) thick PES.

3DSMs were prepared from low EW ionomer solution and the thin support materials supplied by Millipore. Mechanical durability tests were performed on these 3DSMs at 80°C. In the first RH-cycling test, cast Nafion®, NR211, failed around 4,500 cycles as seen in Figure 4. Two 3DSMs that were sintered to 140°C did not fail in the first 5,000 cycles of the first test. A 3DSM that was sintered to 200°C, which is above the melting temperature of the support, failed around 3,500 cycles. The samples were taken off test at 5,000 cycles because the test stand was needed for another project. A second RH-cycling performance test was initiated this spring to test the mechanical durability of 3DSMs. A 1-mil 3DSM sintered to 140°C successfully completed 20,000 cycles (Figure 4) and was removed from the test stand. The RH-cycling test consists of 2 minutes bone dry, 2 minutes at 95% RH at 80°C. The gas flowrate is 1 SLPM, rather than the 2 SLPM industry standard due to test stand limitations.

To improve performance, we tried to impregnate 3DSM supports with 660 and 700 EW material. Ionomer solution concentrations of 30 wt% or greater are needed to adequately fill the porous supports, but increasing the concentration of an alcohol-based ionomer concentration above 10 wt% causes the solution to become too viscous and collapse the UPE 3DSM support. Aqueous-based solutions are less viscous at higher concentrations, but these solutions are incompatible with the hydrophobic supports. Efforts centered on pretreating the 3DSM supports with a hydrophobic solution prior to casting. 3DSMs were successfully cast with pretreatment and PES supports,

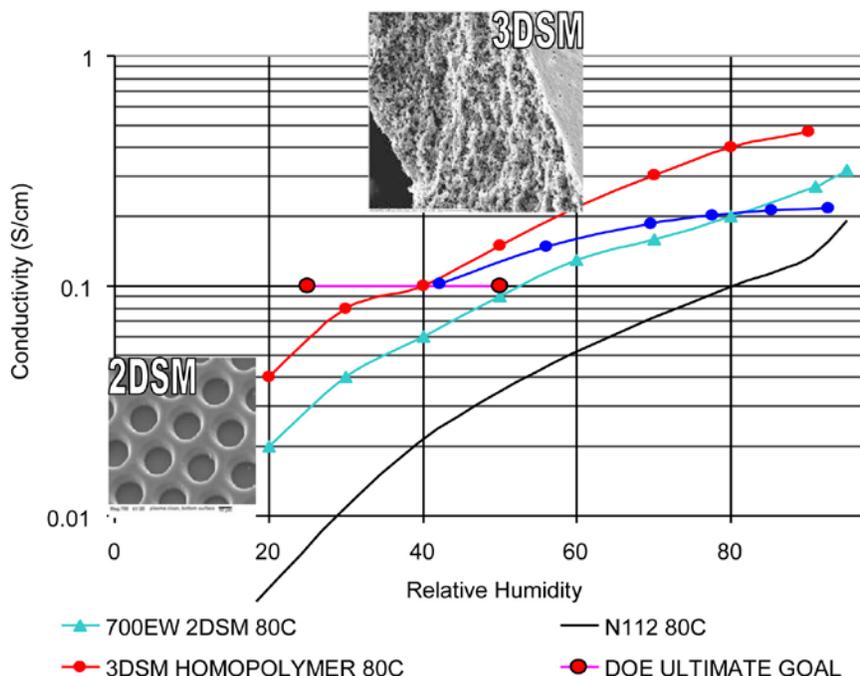

FIGURE 2. Conductivity of 2DSM membrane consisting of 700 EW PFSA in a polyimide support as well as two 3DSMs: one with the SUNY homopolymer at 80°C and a second with highly cross-linked PVEPVE. Insets of the 2DSM and 3DSM membranes are shown.

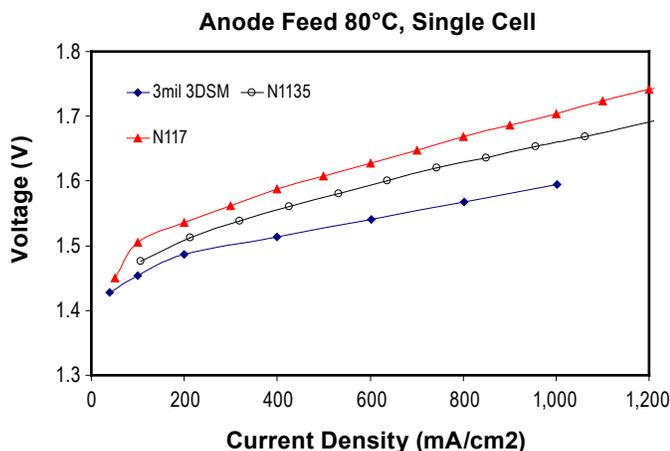

FIGURE 3. Electrolyzer Performance of N1135, N117 and a 3-mil-thick UPE 3DSM Membrane with 820 EW

although the resultant 3DSM was 65 microns thick. Surface oxidation and chlorosulfonation treatment showed dramatic increase in hydrophilicity, but failed to adequately incorporate the 660 and 700EW aqueous dispersions into the supports.

To further increase conductivity PFSA's with even higher acid content are being synthesized at SUNY under the direction of Israel Cabasso. A large number of materials have been synthesized, including the homopolymer of just

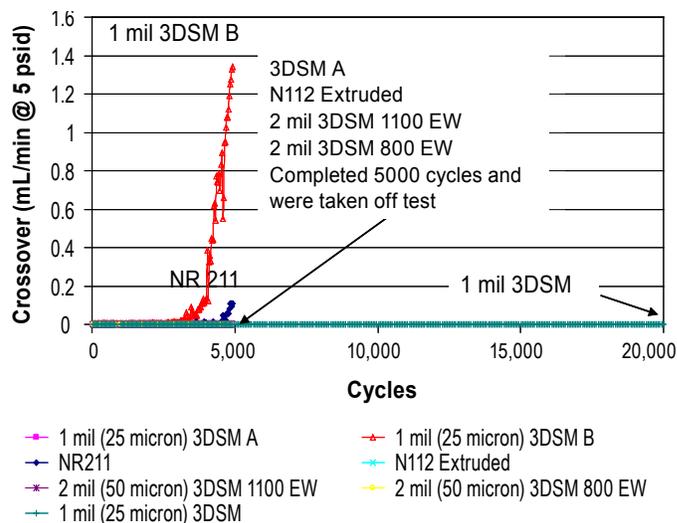

FIGURE 4. RH-Cycling Performance at 80°C for 1- and 2-mil 3DSM and Nafion® Membranes

the active monomer. Improvements in the synthesis of this polymer have led to a film-forming ionomer that can be readily incorporated in GES's 3DSM structures. In the previous years we demonstrated that this material has a conductivity that is approximately twice that of the best 2DSM material to date and approximately five times that of Nafion® 112 over an entire range of RH as seen in Figure 2. Also seen in the figure is that this material comes very close

to meeting the DOE target for conductivity down to 25% RH. Unfortunately this material swelled excessively in water.

Work at SUNY in this past year has centered on reducing this swelling while maintaining the high conductivity at low RH. A highly cross-linked perfluoro (4-methyl-3,6-dioxaoct-7-ene) sulfonyl fluoride (PSEPVE)-based polymer was cast and characterized for conductivity at GES. The conductivity of this polymer was quite high at low levels of RH as seen in Figure 2. Surprisingly the conductivity at higher levels of RH does not increase as quickly as the non-crosslinked materials. We believe that this is due to the lower water contents at higher RH due to the cross-linking. Water sorption isotherms of this material will be conducted to confirm this conclusion.

Conclusions and Future Directions

The DSM with laser-drilled supports has been shown to successfully reduce x-y swelling in high acid content PFSA's over a range of composite dimensions and compositions. Though 2-3 times more conductive than Nafion® 112, it still is short of the DOE's conductivity targets. Work has been

done to synthesize PFSA's with even higher acid content, including the homopolymer that contains only the functional monomer. This polymer, when incorporated in the 3DSM has come very close to meeting the DOE targets. This polymer is water soluble however, and eventually leaches out of the 3DSM support. Efforts have begun to cross-link this polymer to make it insoluble and resulted in a polymer with similar low RH performance that is hydrolytically stable. RH cycling of the 2DSM and 3DSM materials has been completed to demonstrate these materials superior mechanical attributes; each of them surpassing 5,000-19,000 cycles, including a 1-mil 830 EW membrane. We are currently focusing on preparing even thinner (~15 µm) 3DSM's for fuel cell testing. Millipore and the Solar Energy Research Center in Florida are assisting in this effort.

Contract Number: DE-EE0004533

Project Start Date: October 1, 2010
Project End Date: September 30, 2013

Fiscal Year (FY) 2011 Objectives

- Develop and characterize membrane electrode assemblies (MEAs) based on the Dimensionally Stable Membrane (DSM) membrane support technology.
- Identify a cost-effective route to fabricate 10-12 μm thick microporous DSM support films with 50% area coverage (pore density) and 10-20 μm diameter holes.
- Qualify the DSM supports by mechanical, freeze/thaw, and wet/dry testing.
- Develop a continuous coating process using molds.
- Investigate alternative molding procedures.
- Go/No-Go Decision: Demonstrate, by the fourth quarter, a scalable method to produce the desired DSM substrates.

Technical Barriers

This project addresses the following technical barriers from the 3.4.4 (Fuel Cells) and 3.5.5 (Manufacturing R&D) sections of the Fuel Cell Technologies Program Multi-Year Research, Development and Demonstration Plan:

- (A) Durability
- (B) Cost
- (C) Performance
- (A) High-Volume Membrane Electrode Assembly (MEA) Processes

Technical Targets

Progress has been made in achieving objectives within the Fuel Cell Technologies Multi-Year Research, Development and Demonstration Plan. Table 1 lists the DOE's technical targets and where our research stands

to date. There are two other DOE targets for membranes relating to durability, which we have not yet addressed.

TABLE 1. DOE Technical Targets and GES Status

Characteristic	Unit	2015 Target	GES DSM Status

FY 2011 Accomplishments

- Supplied four laser manufacturing companies with polyimide and polysulfone samples to generate a closely packed (50% area density) microporous DSM support via continuous drilling of pores using direct laser ablation method.
- Established an ultraviolet (UV)-shielded cleanroom to fabricate photo-curable polymers as candidates for DSM supports.
- Collaborated with University of Massachusetts Amherst (UMass), Colorado Photopolymer Solutions, and NanoImprint Lithography Technology to optimize the use of photo-curable polymers for rapid microreplication process.
- Designed a protocol to screen various DSM supports which includes procedures to test acid/alcohol resistance, water uptake, substrate adhesion, and mechanical strength for roll-to-roll fabrication.
- Revisited the phase inversion solvent cast method from Phase II and improved the tensile strength and elastic moduli of cast DSM supports by 3-5 fold.

Introduction

Lowering the equivalent weight (EW) of perfluorinated ionomers is one of the few options available to improve polymer electrolyte membrane conductivity, especially in the low relative humidity (RH) regime. GES believes that an approach utilizing perfluorinated ionomers of low EW is an optimal method to achieve the DOE membrane metrics. GES has developed DSMs (Figure 1) to provide a better support for the conductive ionomer. DSMs are composite membranes that include a highly conductive and high acid content ionomer incorporated into a thin and durable polymer support with well-defined pores. Utilizing high strength engineering polymers, DSMs have completely restrained in-plane swelling. Providing a direct through-plane non-tortuous path minimizes the conductivity penalty due to the support structure. Additionally, when filled with low EW perfluorinated sulfonic acid (PFSA) ionomers, they meet nearly all of the DOE's 2015 durability and performance targets, including those for freeze/thaw cycling and wet/dry cycling operation.

As currently manufactured, DSMs are far too expensive for automotive or even stationary applications. This project is directed toward the commercialization of DSMs for highly reliable fuel cell systems operated under harsh environments. The overall objective of this project is to develop a scaled-up fabrication process geared towards roll-to-roll manufacturing of DSMs.

Approach

A major milestone for the project is to identify a cost-effective route to fabricate 10-12 μm thick microporous DSM support films with 50% area coverage (pore density) and 10-20 μm diameter straight pore holes. Currently, four types of DSM support fabrication techniques have been evaluated based on several criteria including DSM performance, scalability, developmental cost, and final DSM cost. Table 2 shows a brief description of each technique along with their strong and weak points.

Results

Continuous Laser Micromachining. This technique involves the use of a dedicated laser to drill holes through a patterned mask, and it allows for direct, one-step generation of porous films without any intermediate processing steps. Throughout the evaluation of this technique, four laser manufacturing companies have received and tested both polyimide and polysulfone films to generate the hole pattern shown in Figure 1. All four companies have failed to meet the stringent requirements for resolution, speed, and projected cost. As an example, a roll-to-roll continuous laser drilling setup reached a lateral accuracy of $\pm 40\mu\text{m}$, much worse than the upper limit of $\pm 3.5\mu\text{m}$ to ensure separation of pores. At continuous operation and very high volume, the final cost (excluding the capital equipment) is estimated to

TABLE 2. Side-to-Side Comparisons of Various DSM Support Fabrication Techniques

Technique	Description	Pros/Cons
Laser Micromachining	Continuously drilling holes using a dedicated laser	Pro: One step fabrication/materials Con: Slow process and high initial costs
UV Microreplication	UV curing of polymers between a mold and a substrate	Pro: Rapid film formation Con: High material risk
Phase Inversion Solvent Casting	Precipitation of polymers on a mold using a non-solvent	Pro: Ease of processing Con: Waste solvent and film shrinkage
Thermal Perforation	Perforation of polymers using an array of microneedles	Pro: One step fabrication/materials Con: Resolution/Ragged features

reduce to $\$200/\text{m}^2$, still an order of magnitude higher than the targeted value of $\$20/\text{m}^2$. Based on these results and the high initial and operational costs, the use of continuous laser micromachining is largely eliminated.

Microreplication of Photo-Curable Polymers. This is a soft lithography approach where ultra-fine (sub-micron) patterns can be generated. It requires the production of a master template, followed by several microreplication processes to obtain the resulting DSM support and eventually the DSM itself after application of the ionomer layer(s). Figure 2 shows an exemplary process flow where a low surface energy mold is applied on a precursor-coated backing layer followed by UV curing to freeze the polymer

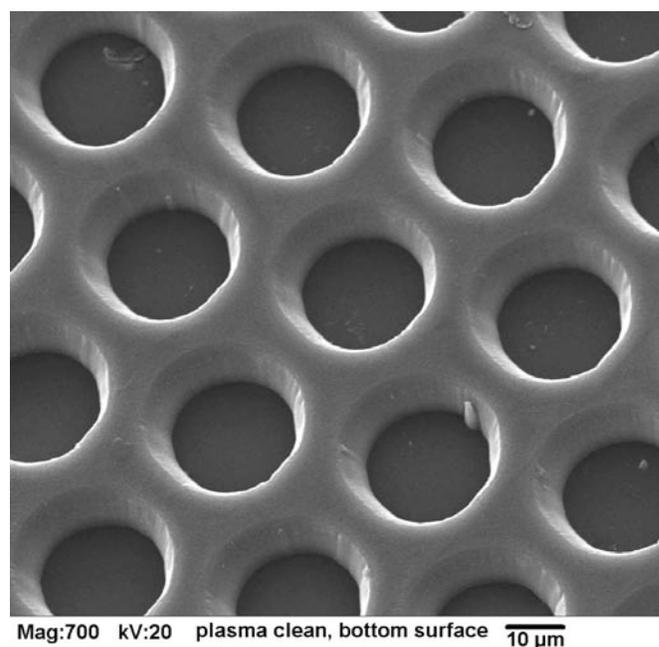

FIGURE 1. Scanning Electron Microscope Photograph of Matrix Support for Low EW PFSA

in place. When the mold is removed, this results in a continuous DSM support with well-defined pores. Due to low material costs and fast processing, this is one of the most promising techniques to meet the target cost of \$20/m². GES has successfully evaluated a series of photo-curable polymers as DSM support candidates. A UV-shielded cleanroom facility was established to accommodate UV-sensitive material processing. To screen and validate polymers as DSM supports prior to the microfabrication at UMass, commercially available formulations of polyimide, epoxy, thiol-ene, and urethane were cast from their precursors and monomers to desired thickness. Controlled exposure to UV-light yielded films that were tested for water uptake, acid resistance, and dimensional stability at temperatures up to 95°C. Polymers that successfully passed the first stage were then subjected to extensive mechanical testing by immersing the films in hot (80°C) water and determining their static (tensile strength, elongation, modulus) and kinetic (creep under stress) mechanical properties. Photo-curable polymers showed very little water uptake, high dimensional stability, and low creep elongation, all superior to that of the ionomers in water (Nafion®). However, their tensile strength and moduli suffer possibly due to the presence of unreacted monomers.

Phase Inversion Solvent Casting. Phase inversion solvent casting technique, first used during Phase II of this project, aimed to develop a new technology to fabricate DSM supports that are less expensive and easier to scale up compared to the laser micromachining. Poly(dimethyl siloxane) (PDMS) elastomer molds, inverted (pin) pattern of Figure 1, were replicated by GES from a master template fabricated at Harvard University's Center for Nanoscale Systems. In this process, polysulfone was dissolved in a solvent, followed by casting on PDMS to fill the micromold as shown in Figure 3. This assembly was then transferred into a gelation bath filled with non-solvent (e.g. water),

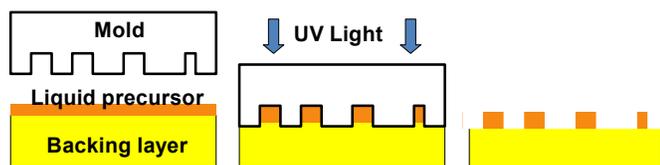

FIGURE 2. Liquid Displacement Method using a Prefabricated Mold followed by UV-Curing to Yield Porous DSM Support

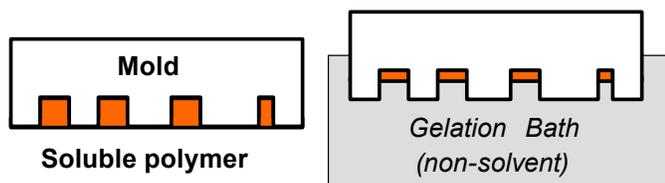

FIGURE 3. Schematic Representation of the Phase Inversion Solvent Casting Process to Precipitate a Polymer in a Non-Solvent

miscible with the initial solvent. This combination yielded the rapid precipitation of the polymer inside the micromold to form a film with well-defined micropores. In Phase II, this approach showed great promise for integration into a fast roll-to-roll process; however, the support prepared by this process is usually not strong enough to withstand further processing and has sponge-like morphology to result in high water uptake. To circumvent this issue, a film has been cast on a PDMS micromold followed by annealing at temperatures above its T_g to show 3-5 fold increase in both elastic moduli and tensile strength.

Thermal Perforation with Microneedles. If a scalable route can be established for direct perforation of polymers to yield porous support layers, it may prove to be a very attractive technique since the resulting support structure will have identical performance unlike the case for photo-curable and solvent cast films where further material validation is required upon fabrication. To further explore this path, GES has partnered with an acclaimed company in the area of microfabrication to employ embossing (puncturing) of softened thermoplastics using an array of microneedles. Figure 4 shows the preliminary results from a trial run performed for GES where an array of microneedles is used to puncture an 8 μm thick polysulfone (PSU) film. PSU is the ideal material choice for this application due to its low cost, superior mechanical properties and low softening temperature as well as its insignificant dimensional changes in all three axes.

Conclusions and Future Directions

The goal by the end of fourth quarter is to demonstrate a scalable process for cost-effective manufacturing of DSM for fuel cells. In addition to further investigation of feasibility of direct laser machining and mold-based phase inversion cast methods, GES has shown two additional methods that will be capable of performing this goal. The microreplication method requires further validation of mechanical properties of photo-curable polymers, which will be performed in collaboration with UMass. The PSU supports generated by thermal perforation method will be inspected by GES to determine whether the method can produce a material with closely packed micropores to meet the 50% porosity

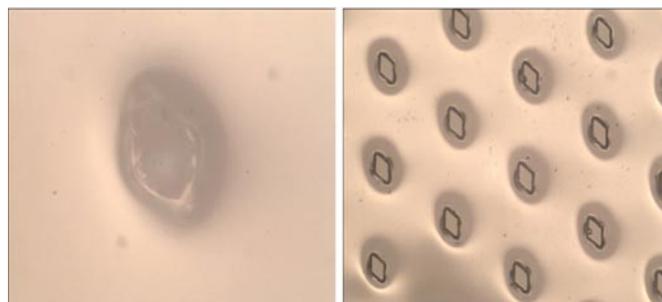

FIGURE 4. Optical Micrographs of a PSU Film Punctured using Microneedles shown at 10X (left) and 40X (right) Magnification

requirement. GES will select the most promising fabrication route and focus on scaling, performance optimization, and cost reduction.

Contract Number: DE-FC36-06GO16039

Project Start Date: March 1, 2006

Project End Date: June 30, 2012

Fiscal Year (FY) 2011 Objectives

The project objectives are to optimize routes to rigid rod poly (phenylene sulfonic acids) (PPDSA), polymers that retain high conductivity at low humidity, develop methods to make water-insoluble polymers and characterize the materials as proton exchange membranes (PEMs). The requirements are:

- Analyze the Ullman polymerization reaction in order to increase polymer molecular weights and decrease reaction time.
- Increase the polymer sulfonic acid density and water absorption: use phenylene disulfonic acid monomer to make homo- and co-polymers.
- Develop reliable methods for making water-insoluble, dimensionally stable PEMs possibly by grafting non-polar groups on the backbone and crosslinking.
- Synthesize comonomers that can be copolymerized to produce water-insoluble copolymers either directly or in a subsequent step.
- Characterize polymers, copolymers and grafts to understand the relationship between molecular structure, supermolecular organization and PEM properties.
- Submit the most successful materials for intensive testing.

Technical Targets

This project involves the synthesis and characterization of homo- and co-polymer rigid-rod aromatic sulfonic acids and developing methods to make them dimensionally stable.

- Our PEMs have passed the 2005 goals for membrane conductivity and probably reach the 2015 goals.
- Earlier tests of MeOH permeability (<0.04 mA/cm² for a 20 μ thick film at 100°C with a 2/1 MeOH/H₂O gas input) imply that the very polar membrane environment should reduce oxygen and hydrogen crossover to values much lower than the target values.
- The starting materials are relatively cheap; there are only two steps from commercial starting materials, fuming sulfuric acid and dibromo benzene (or dibromo biphenyl), to the homopolymer sulfonic acids. Copolymers could raise the cost. (Also, it may be possible to replace dibromo benzene with dichloro benzene, lowering the raw materials cost by a factor of 5.)

Remaining Barriers

- Polymers have low elongation (6-9%) and tear easily.
- Polymer molecular weights are too low. Higher molecular weight should give better mechanical properties.
- Grafting and crosslinking succeeded; good PEMs were made. However, better grafting methods need to be developed.
- Procedures for scaling up polymer production without lowering molecular weight have not yet been developed.
- Crosslinked films swell about 15% in the x and y directions and 30 to 40% in the z direction going from 0 to 98% relative humidity (RH). Can swelling be reduced without decreasing conductivity?

Technical Targets

Progress towards meeting the technical targets for PEMS and membrane electrode assemblies (MEAs) is shown in Table 1.

Fiscal Year 2011 Accomplishments

- PPDSA and copolymers containing the biphenyl group (B2P8) were made in molecular weights high enough that cast films could be handled easily.
- One to 16 mole% biphenyl groups were grafted on the polymers to form biphenyl sulfones.
- Films cast from the grafted polymers were completely crosslinked by heating at 210°C for three hours with no loss of acid over that required to crosslink. Crosslinked

*Sample thickness was ~80 micrometers. A 25 micrometer thick film could meet the requirements. A less heavily grafted film (7% instead of 12%) could meet the requirements at 80 micrometers thick.

polymers were stable for at least two hours at 225°C. Some acid was lost after 2 hours at 250°C.

- Crosslinked films were dimensionally stable, retaining the high conductivity at low RH of the starting graft polymers.
- MEAs prepared from crosslinked films were tested in fuel cells. The best were slightly worse than Nafion211®. This is a very good result for first tests on a completely new class of materials.
- High viscosity copolymers of dibromobenzene disulfonic acid and dibromofluorene disulfonic acid were made. These can be grafted and crosslinked to give dimensionally stable polymers with exceptionally high milliequivalents of acid groups per gram of material (IECs) and high conductivity at low RH (higher than the biphenyl grafted polymers).

Introduction

There are many problems associated with the normal aromatic sulfonic acid PEMs. The better conducting materials swell very much in water. Even with these materials, conductivity drops rapidly as humidity is lowered [1]. Block polymers swell less at high humidity,

but conductivity is still poor at low RH [2]. They can be used only at high humidity which limits the fuel cell operating temperature to < 90°C. The materials described in the following were designed to hold water very strongly at low humidity. They could be used effectively at higher temperatures, up to at least 120°C, with little or no added water in the fuel stream since the water generated in the reaction should be sufficient to maintain high conductivity. High temperature operation has the additional advantages that kinetics are faster, lower purity hydrogen can be used and heat can be removed easily.

Approach

Our approach derives from a combination of polymer structure analysis and cost considerations. What type of polymer backbone can have high sulfonic acid content, hold water strongly, and yet have dimensional stability. The analysis suggested that PPDSA, rigid rod liquid crystals that organize with all molecules locally parallel, should be suitable. These structures have small cross-section backbones with projecting sulfonic acid groups. Absorbed water separates the chains. As water is lost at low humidity, the sulfonic acids hit other acid groups or a neighboring polymer backbone. The molecules still have voids that hold water (frozen in free volume): further water loss compresses the molecule, which distorts bond angles and requires high energy. The last few waters are difficult to remove and resorb easily. Water causes the structure to expand perpendicular to the parallel polymer axes. The final structure can be dimensionally stabilized by grafting cross-linking groups on the backbone and subsequently crosslinking them [3] (PPDSA). Grafted groups protrude further from the backbone than the acid groups; this increases the chain (rigid rod) separation and thus can increase the frozen-in free volume [4]). This structural design generates non-collapsible nanopores lined with a high density of sulfonic acid groups that hold water very strongly.

Polymers with grafted non-polar groups, reported last year, lost coherence at high humidity; the film flowed under pressure and disintegrated in water. Crosslinking avoids these problems. Because the molecules are rigid rods, grafted groups react only intermolecularly to cross-link with sulfonic acids on neighboring chains. Thus, a relatively low mole fraction of crosslinkable groups should make such polymers dimensionally stable with little loss of conductivity. This approach has succeeded for these materials.

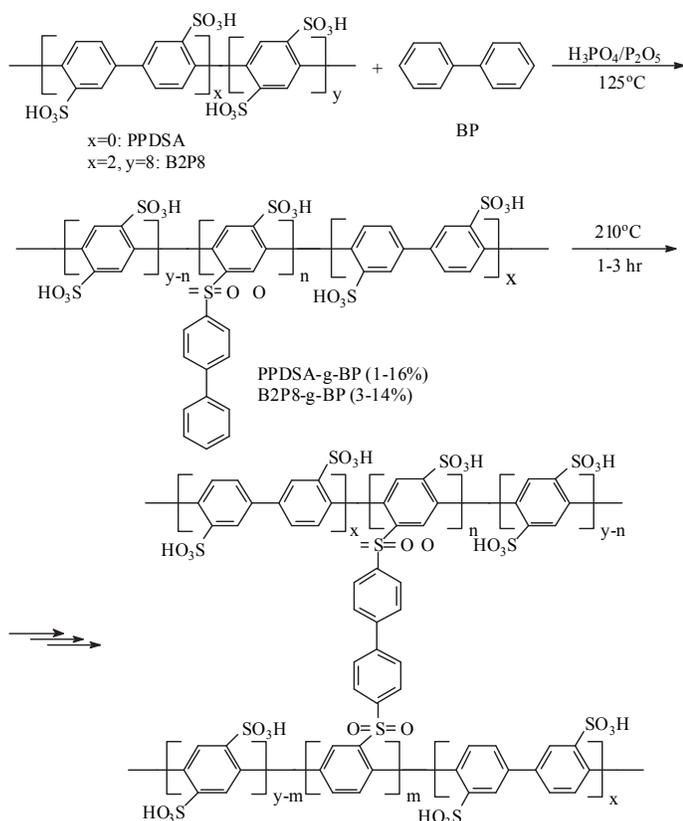

Another approach to generate frozen-in free volume was presented last year. The idea was to make a two-dimensional lattice containing large pores. The molecules should stack to create nano-channels that would contain enough water to give good conductivity along the channels and hold the water even at very low humidity. Cast films with all molecules parallel to the film surface should have very high through conductivity at low RH. The idea was tested and it worked, but as usual, there were complications.

Results

PPDSA and B2P8 Copolymers

Copolymerization: The polymers used for most of this research were PPDSA and a 20/80 copolymer of 1, 4-dibromo phenylene 2, 5-disulfonic acid (DBPDSA) and 4, 4'-dibromobiphenyl 3, 3'-disulfonic acid (DBBPDSA), B2P8. As reported last year, both were made with reasonably high molecular weights. As expected from the discussion above, λ at low RH rose rapidly and stabilized at 2 to 3 waters higher than Nafion117[®] at higher RHs. This resulted in high conductivity down to very low RHs but with high swelling and poor mechanical properties.

Grafting and Crosslinking: Grafting of alkyl benzene groups on the polymer was abandoned since the resulting grafts had very poor mechanical properties. We have shifted to grafting cross-linkable groups. Biphenyl, the first of many possible cross-linkable structures, was grafted on the polymer backbone to generate dangling biphenyl sulfone groups, Scheme 1. Once one benzene ring reacts, the second benzene ring is deactivated; soluble polymer is isolated. Cast films could be almost completely crosslinked by heating under vacuum at 210°C for at least 1 hour. Studies of heating times and temperatures showed that the polymer was stable for at

SCHEME 1. Grafting and Crosslinking of PPDSA Polymers and Copolymers

least two hours at 225°C, but showed some acid loss after 2 hours at 250°C. The 10 and 12 mole% grafts were extensively characterized, though conductivity and water absorption data were obtained for most grafts.

1, 4-Dibromobenzene 2, 5-disulfonic acid was successfully copolymerized with 2, 7-dibromofluorene 3, 5-disulfonic acid in 10/1 and 20/1 mole ratios to give high viscosity copolymers. However, we still have not been able to graft benzyl groups effectively on the fluorene moieties. Each should add two benzyl groups, but as yet we have only reached about 0.5 groups. Films crosslink when heated but they swell too much to be useful.

Properties: Grafted polymer films showed almost the same conductivity and mechanical properties before and after crosslinking. Swelling at a given graft percent was identical up to 50% RH, independent of crosslinking. Crosslinked PEMs (7 to 16 mole% biphenyl graft) swelled 90 to 60% when the RH rose from 0 to 98%. The x and y dimensions increased only 10 to 15% for all crosslinked films. At 98% RH, λ before crosslinking was about 2.5 to 3 higher than after crosslinking, with a corresponding dimensional increase.

Stress/strain measurements were made on many films before and after crosslinking. Elongation at break (22 to 30% RH) varied randomly between 6 and 9%; crosslinked films broke at much higher stress (35 to 45 MPa) than the uncrosslinked films (20 to 25 MPa). Stress concentrators, bubbles or particles in the film or edge defects, probably initiated failure. Lower humidity raised the modulus and break stress but lowered break elongation. Higher humidity drastically lowered the modulus of the uncrosslinked films; they tended to creep at constant force above 3% elongation.

Water absorption from 0 to 98% RH was measured for grafted films before and after crosslinking. Uncrosslinked films had final λ s of 12.5 to 14.5; when crosslinked, λ decreased to 8.5 to 12. Differential scanning calorimetry measurements showed that about 9 molecules of water per acid group were strongly bound, much higher than that found for Nafion 117[®], and others.

Parallel conductivity was measured at 80°C as a function of RH for many films, both here and at the Florida Solar Energy Center (FSEC). Results agreed within experimental error. Conductivity decreased with higher grafting; however on a log conductivity vs. RH graph, all plots were parallel. Crosslinking did not change conductivity even though it decreased the IEC. Even at the highest grafting levels, low RH conductivity was still very high. Through plane conductivity for a 12 mole% biphenyl grafted and crosslinked B2P8 copolymer, uncorrected for electrode/film resistance, is shown in Figure 1 (measured by Dr. Kevin Cooper, Scribner Associates). The through plane conductivity at 80°C is about that of the parallel conductivity (measured at Case and at Bekktech). Its conductivity at 120°C and 30% RH is 100 mS/cm, close to the DOE 2015 goals. We expect that materials with a lower percentage of grafting will have higher conductivity.

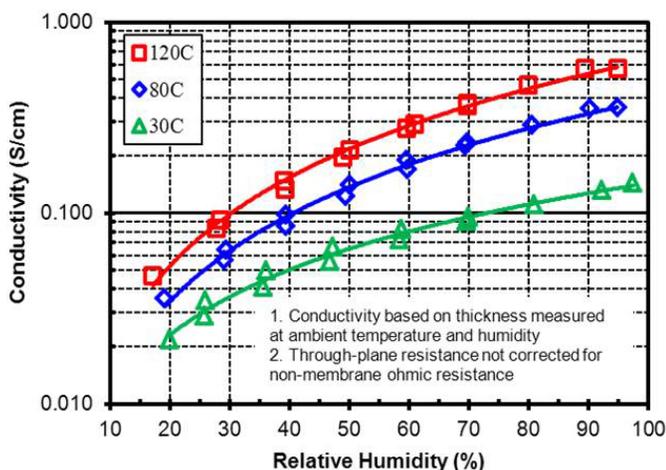

FIGURE 1. Through-Plane Proton Conductivity for B20P80-g-BP12%-210C-3hr (D7) as a function of RH at 30, 80 and 120°C

Fuel Cell Testing: Several grafted materials (both as uncrosslinked (D9) and as a final crosslinked film (D7) were sent to the FSEC for testing in MEAs. They tested the film crosslinked at Case Western University (D7) and a second film (D9) cast and crosslinked at FSEC. Both showed high hydrogen leakage, probably from small tears generated in the brittle films during electrode application. Figure 2 shows some results for D7, the best film, a B2P8 copolymer grafted with 12 mole% biphenyl. The hydrogen leakage lowers the voltage at low current densities. Above 100 mA/cm², the curves follow each other closely, with the power output for the D7 cell about 95% that of the reference Nafion211® cell over the useful current range. Considering that this was the first fuel cell test on a new material with very different chemical and mechanical properties from the normal PEMs, such good performance is remarkable. We expect that a film

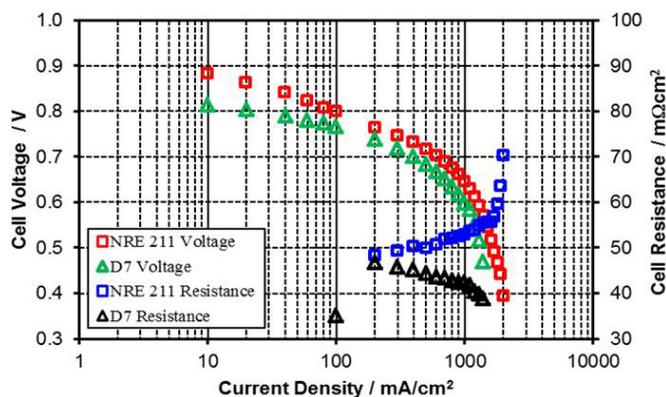

FIGURE 2. Single-Cell Performance of an MEA using B2P8-g-BP12%-210C-3hr (D7, 80 μ thick) compared to that of Nafion® (NRE211) at 80°C, 100% RH, H₂/air, Ambient Pressure (Work done at FSEC.)

without defects should have very low hydrogen and oxygen permeability; the highly polar aqueous phase is a very poor solvent for the non-polar gasses while the organic phase consists of rigid aromatic rings that cannot dissolve the gasses.

A summary of the results for films D7 and D9 compared with that of NRE211, is shown in Table 2. D6, the first entry, is an octyl benzene graft; this could not be crosslinked and disintegrated during testing. The major problem was gas leakage through the membrane that varied widely from one day to the next (probably due to micro tears that opened and closed with changing humidity and history). When gas leakage was accounted for, the membrane performance was about that of DRE211. Since the films had lower resistance, this was unexpected; MEA preparation needs to be improved. However, these are excellent results for a first study.

TABLE 2. First Tests of Case Membranes against NRE211, compared to DOE 2015 Targets

Characteristic	Units	Target 2015	D6 ^d	D7 ^d	D9 ^d	NRE211

^d D6 is B2P8-g-16 mole% n-octylbenzene. D7 is B2P8-g BP 12%, cast and crosslinked for 3 hrs at 210°C at Case Western Reserve University. D9 is the same polymer, cast and crosslinked at FSEC.

N/D - not determined

Conclusions and Future Directions

- We have made PEMs with very high conductivity at low RH and have been able to dimensionally stabilize them through crosslinking.
- Some crosslinked membranes were tested as MEAs in single fuel cells and performed well for a first study.
- The major problem for these materials is their low elongation at break, 6 to 9%, which promoted the formation of micro-tears in the MEAs during their preparation. This is mainly the result of their rigid-rod structure. However, elongation will increase with higher molecular weight.
- There has been no study of possible membrane cost. Some procedures used are fine for laboratory preparations but are wasteful. Work will start on lower cost approaches - possible alternate monomers and grafting methods.
- In the coming year, we will concentrate on making higher molecular weight polymers. We are considering two approaches. First, determine the best polymerization conditions. Second, develop comonomers that increase polymer solubility, allowing it to reach higher molecular weight before it precipitates. With these approaches, we should be able to reach high modulus, high elongation PEMs.
- In addition, grafting procedures need to be improved. Grafting is inhomogeneous and expensive. Inhomogeneity reduces crosslinking effectiveness: poorer mechanical properties for a given percent graft. We will work to develop methods to graft homogeneously using minimal amounts of reagents. This should result in PEMs with higher conductivity and lower swelling.
- As better PEMs are made, they will be submitted to the FSEC for extensive testing as MEAs.

Start Date: March 1, 2006

Projected End Date: February 28, 2012

Fiscal Year (FY) 2011 Objectives

- Fabricate a new class of nanofiber-based proton conducting membranes using different sulfonated polymers.
- Characterize the membranes in terms of swelling, proton conductivity, thermal/mechanical stability, and gas permeability.
- Optimize the membrane structure (fiber diameter, mat density, polymer ion-exchange capacity, choice of impregnation polymer, etc.) to achieve the DOE's technical targets for membranes.

Technical Barriers

This project addresses the following technical barriers from the Fuel Cells section of the Fuel Cell Technologies Program Multi-Year Research, Development and Demonstration Plan:

(A) Durability

(B) Cost

(C) Performance

Technical Targets

This project is focused on the fabrication and characterization of a new class of proton conducting membranes for high temperature hydrogen/air fuel cells. The technical targets of this project are listed in Table 1.

TABLE 1. Progress towards Meeting Technical Targets for Membranes

Characteristic	Units	Target 2015	2011 Project Status

FY 2011 Accomplishments

- Fabricated nanofiber composite membranes via a dual fiber electrospinning, where perfluorosulfonic acid (PFSA) proton conducting fibers and uncharged polyphenylsulfone (PPSU) nanofibers are simultaneously electrospun.
- Further developed two methods for processing the dual fiber mat into a functional fuel cell membrane by:
 - (i) allowing the PFSA ionomer fibers to soften and flow without affecting the PPSU mat in order to fill the voids

between PPSU fibers (the nanofiber PPSU becomes a membrane reinforcement mat) and (ii) allowing the PPSU nanofibers to soften and flow to fill all voids while maintaining the structure of the Nafion[®] mat. Membranes were prepared from method (i) using DuPont's Nafion[®] and 660 equivalent weight (EW) PFSA from 3M Company and from method (ii) using Nafion[®] PFSA.

- Nanofiber membranes were characterized in terms of proton conductivity, in-plane, volumetric, and gravimetric water swelling, and mechanical properties.
- Electrospun nanofiber Pt/C fuel cell cathodes were fabricated and tested.

Introduction

Proton exchange membrane (PEM) hydrogen/air fuel cell operation with lightly humidified gases at 120°C would be highly advantageous with regards to heat rejection from a fuel cell stack, compatibility with automotive radiators, tolerance to CO impurities in the hydrogen gas stream, and fast electrode kinetics. For PEM fuel cell operation at temperatures ≤80°C and high RH conditions, PFSA proton conductors (e.g., Nafion[®]) are the membrane material of choice due to their high conductivity and chemical/mechanical stability. Unfortunately, the conductivity of PFSA membranes drops dramatically at temperatures >100°C under low humidity conditions [1] due to an insufficient number of membrane-phase water molecules for protons to dissociate from sulfonic acid sites, a loss of percolation pathways for proton movement, and structural changes in the polymer which cause membrane pores to collapse.

In order to overcome the limitations of existing membrane materials, a new approach to fuel cell membrane design and fabrication has been developed, where a three-dimensional interconnected network of proton-conducting polymer nanofibers/nanocapillaries is embedded in an inert/impermeable polymer matrix. The nanocapillary network is composed of a high ion-exchange capacity sulfonic acid polymer to ensure high water affinity and a high concentration of protogenic sites. The inert (hydrophobic) polymer matrix controls water swelling of the nanofibers/nanocapillaries and provides overall mechanical strength to the membrane. First-generation membranes [2] were made using sulfonated poly(arylene ether sulfone) with/without sulfonated octaphenyl polyhedral oligomeric silsesquioxanes (sPOSS) to further boost conductivity. Norland Optical Adhesive 63 (NOA63) was employed as the inert embedding polymer. Second-generation membranes were fabricated with nanofibers containing 850 EW PFSA (from 3M Corporation) with/without sPOSS [3]. These films met the DOE's Year 3, 3rd quarter Go/No-Go conductivity target of 100 mS/cm at 120°C and 50% RH. Third-generation

films were made using a new dual-fiber electrospinning approach where ionomer and inert polymer are electrospun simultaneously. Advantages of this method over traditional membrane fabrication techniques, e.g., polymer blends or the impregnation of an ionomer in an inert matrix, are: (i) there is no separate polymer impregnation step, (ii) the same dual-fiber mat can be processed into two different membrane morphologies: proton conducting ionomer nanofibers embedded in an uncharged/inert polymer matrix and inert/uncharged polymer nanofibers embedded in (and reinforcing) an ionomer matrix, (iii) there is wide choice of polymers for the ion conduction and inert (uncharged) polymers, (iv) there is intimate mixing of polymer components in the dry state with a polymer component domain size (the fiber diameter) as small as 100 nm, (v) separate polymer components are used for the mechanical and proton-conducting functions of the membrane, and (vi) the domain size and loading of the proton-conducting phase can be easily and independently controlled.

Approach

Membrane Fabrication – Membranes were prepared by a newly developed dual nanofiber electrospinning technique using either 1100 EW Nafion[®] or 660 EW PFSA from 3M Corporation as the proton conducting material and Radel[®] R-5500NT polyphenylsulfone (PPSU) from Solvay Advanced Polymers LLC as the inert/uncharged polymer. PFSA materials were electrospun using 0.33-2% poly(ethylene oxide) as a carrier polymer (which was later removed by boiling the final membranes in water). PFSA and PPSU nanofibers were electrospun simultaneously using two separate needle spinnerets. Suitable post-treatment converted the dual-fiber mats into fully dense and defect-free membranes, while maintaining the nanofiber morphology of one polymer component. Membranes were made where: (i) PFSA nanofibers were surrounded by a PPSU matrix (compacted the mat at room temperature and 3,500 psig for a few seconds, exposed the mat to chloroform vapor at 25°C for 16 minutes, and then annealed the membrane for 2 hours at 150°C in vacuum) and (ii) PPSU nanofibers were surrounded by PFSA ionomer (hot pressed the mat at ~15,000 psig and 127°C for 40 seconds and then annealed at 150°C for 2 hours in vacuum). Membranes were evaluated and contrasted in terms of in-plane proton conductivity, in-plane, volumetric, and gravimetric swelling in water, and mechanical properties.

Electrode Fabrication – An electrospinning ink was prepared by mixing Pt/C catalyst powder (40% Pt on carbon black, Alfa Aesar), Nafion[®] powder, and 450,000 MW poly(acrylic acid) (MW=450,000 g/mol, Aldrich) in an isopropanol/water solvent (2:1 wt ratio). The total polymer and powder content was 13.4 wt%, where the Pt/C:Nafion[®]:poly(acrylic acid) weight ratio was 75:15:10. The ink was electrospun at 1.5 ml/h with an applied voltage of 7 kV. Nanofibers were collected on a bare rotating drum or on carbon paper (SIGRACET[®])

GDL 25 BC, Ion Power, Inc) that was fixed to the drum. The drum oscillated horizontally to improve the uniformity of deposited nanofibers. Fuel cell membrane electrode assemblies (MEAs) were prepared with a Nafion[®] 212 membrane and a decal-processed anode at a loading of 0.40 mg_{Pt}/cm². Electrospun cathodes with a Pt-loading of 0.1 mg/cm², 0.2 mg/cm² and 0.4 mg/cm², respectively, were hot-pressed onto anode-coated Nafion[®] membranes. The resulting MEAs were evaluated in a series of electrochemical and fuel cell tests.

Results

Nanofiber Composite Membranes with 660 EW PFSA – Figure 1 shows proton conductivity as a function of RH for a nanofiber composite membrane (70 vol% 660 EW PFSA + 30 vol% PPSU with an effective ion-exchange capacity of 1.23 mmol/g), as compared to commercial Nafion[®] 212 and a solution cast film composed of neat 660 EW PFSA. The nanofiber composite film is more conductive than Nafion[®] 212 due to its higher ion-exchange capacity. The conductivity of the composite is slightly below a neat 660 EW film due to dilution of ionomer by the PPSU reinforcing nanofiber mat. The composite membrane, however, has greatly reduced in-plane volumetric swelling; 5% as compared to 24% for Nafion[®] 212 and the 84% for the neat 660 EW film (swelling was measured in 23°C water). Thus, the nanofiber composite has more than twice the conductivity of Nafion[®] 212 over a wide humidity range and 5-times lower in-plane swelling. Low in-plane membrane swelling has been identified as an important property that improves the durability of an MEA during fuel cell operation. Based on the 50% RH conductivity in Figure 1 (at 80°C), the nanofiber composite membrane

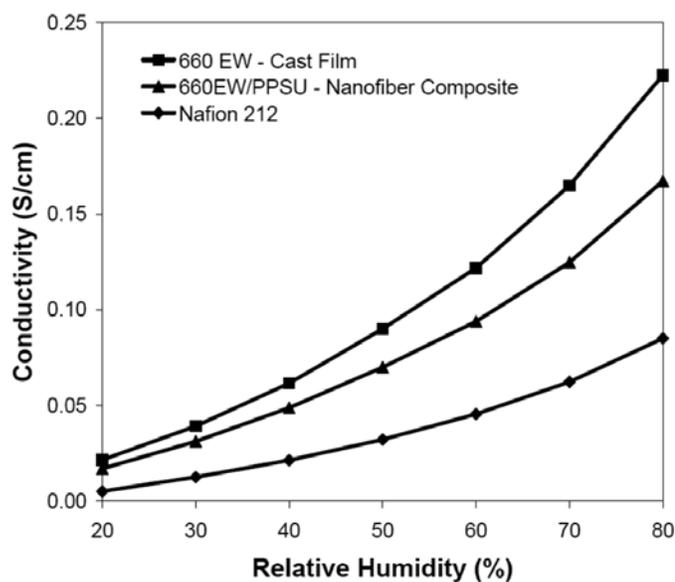

FIGURE 1. Proton conductivity of a nanofiber composite membrane (70 vol% 660 EW PFSA and 30 vol% polyphenylsulfone) at 80°C as a function of RH.

should have a proton conductivity of 0.090-0.095 S/cm at 120°C (slightly below the DOE target of 0.10 S/cm). The conductivity target can be achieved by decreasing slightly the PPSU content of the composite membrane or by using a slightly lower EW PFSA.

Nanofiber Composite Membranes with Nafion[®] – Proton conductivity (in 23°C liquid water) as a function of Nafion[®] volume fraction for the two nanofiber membrane structures (Nafion[®] with a PPSU nanofiber mat and Nafion[®] nanofibers surrounded by PPSU) is shown in Figure 2. There are no significant differences in conductivity between the two structures and proton conductivity scaled linearly with Nafion[®] volume fraction. The two morphologies exhibit the same volumetric and gravimetric water swelling but the in-plane swelling differs (see Figure 3), with the PPSU nanofiber reinforcing mat morphology exhibiting less swelling. The mechanical properties of the two composite membrane morphologies also differ, with the Nafion[®] nanofiber + PPSU matrix membrane exhibiting a larger Young's modulus (550 MPa) and proportional limit stress (30 MPa) than the inverse structure.

Nanofiber-Based Fuel Cell Cathode – Nanofiber cathode MEAs (where the average electrospun nanofiber diameter was 470 nm) performed very well in a hydrogen/air fuel cell operating at 80°C without back pressure. Exceptionally high fuel cell power densities were achieved at a low Pt loading, e.g. 524 mW/cm² at 0.6 V for 0.1 mg_{Pt}/cm², as shown in Figure 4. The catalyst mass activity, as measured at 0.9 V in an 80°C H₂/O₂ fuel cell with a pressure of 150 kPa_{abs}, was also exceptionally high at 0.23 A/mg_{Pt}. The accessible electrochemical surface area of the nanofiber cathode was very high (114 m²/g_{Pt}) and it exhibited improved long-term stability vs. a decal cathode.

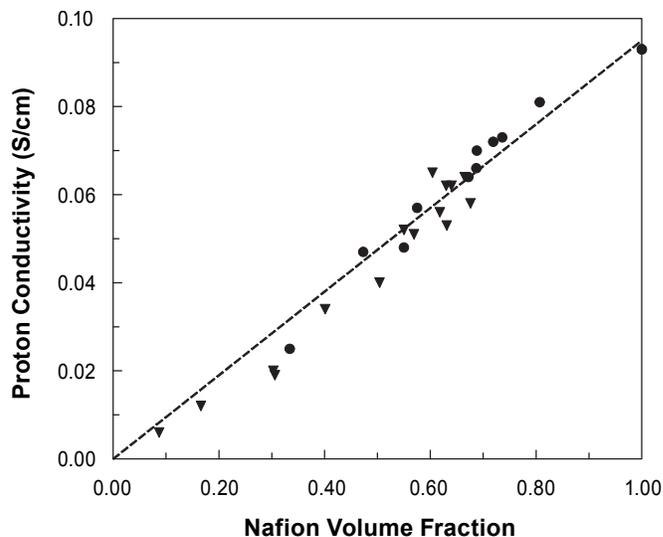

FIGURE 2. Proton conductivity of Nafion[®]/PPSU composite membranes as a function of Nafion[®] volume fraction. Conductivity measured in liquid water at room temperature. (▼) Nafion[®]-fibers/PPSU-matrix, (●) PPSU-fiber/Nafion[®]-matrix.

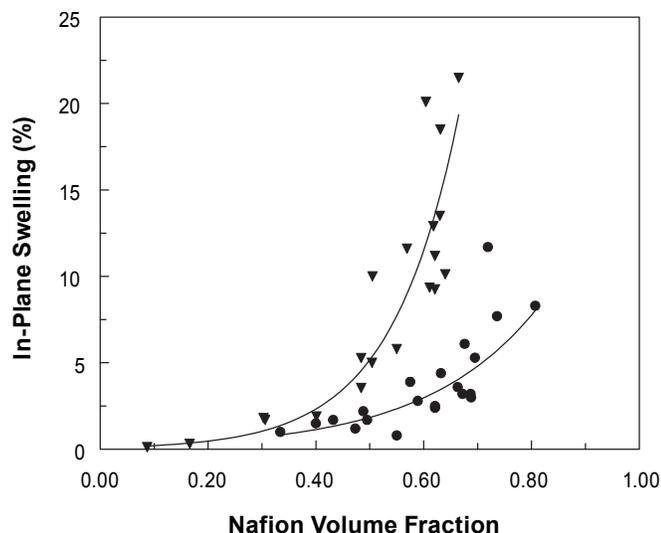

FIGURE 3. In-plane swelling of Nafion®/PPSU composite membranes as a function of Nafion® volume fraction. Swelling was measured in 100°C water. (▼) Nafion®-fibers/PPSU-matrix, (●) PPSU-fiber/Nafion®-matrix.

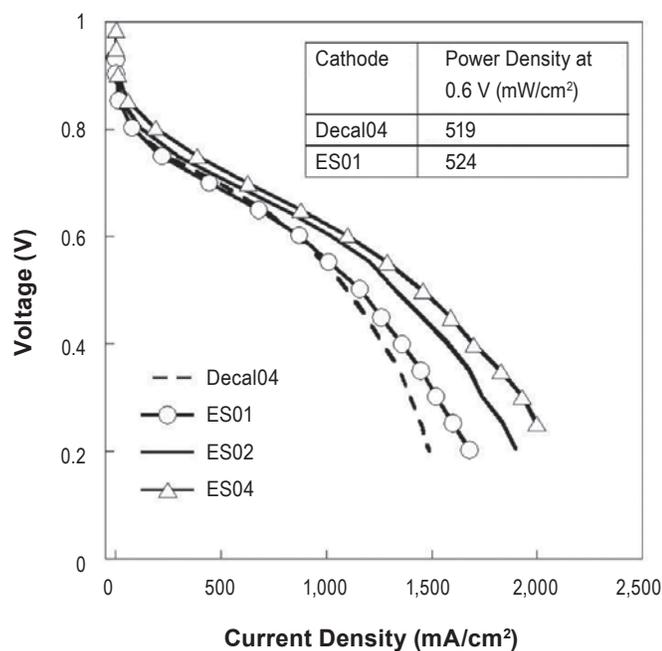

FIGURE 4. H₂/air fuel cell polarization curves at 80°C and ambient pressure with different cathodes, a Nafion® 212 membranes, and a 0.4 mg/cm² decal anode. Cathodes: Decal04 = 0.4 mg/cm² decal; ES01 = 0.1 mg/cm² nanofiber; ES02 = 0.2 mg/cm² nanofiber; ES04 = 0.4 mg/cm² nanofiber.

The outstanding performance was associated with a more uniform distribution of Pt/C particles and Nafion® binder in the nanofibers, thus allowing for better proton transport and oxygen diffusion to catalyst sites during fuel cell operation.

Conclusions and Future Work

Conclusions

- Two different membrane morphologies were generated from a dual nanofiber (Nafion® + PPSU) electrospun mat: Nafion® with a reinforcing nanofiber mat of PPSU and a nanofiber mat of Nafion® surrounded by PPSU polymer.
- The proton conductivity and volumetric/gravimetric water swelling are identical for the two membrane structures. The in-plane water swelling for membranes with a reinforcing PPSU mat is less than the inverse structure and the mechanical properties (Young's modulus and proportional limit stress) of membranes with a Nafion® nanofiber mat embedded in PPSU are better than films with the inverse structure.
- Dual fiber composite membranes were prepared and evaluated, where a PPSU nanofiber mat was surrounded by 660 EW PFSA (from 3M Corp.). The presence of the PPSU reinforcing mat lowered significantly volumetric and in-plane water swelling, for a membrane with 70 vol% PFSA. The membrane proton conductivity at 80°C and 50% RH was high (0.07 S/cm).
- Fiber composite membranes were estimated to cost \$27/m² (\$8/m² for sulfonated fluoropolymer and polyphenylsulfone and \$19/m² for electrospinning and fiber mat processing).
- An electrospun nanofiber cathode was fabricated, where the fiber composition was 75 wt% Pt/C powder, 15 wt% Nafion®, and 10 wt% poly(acrylic acid). In a H₂/air fuel cell, a nanofiber cathode at 0.1 mg_{Pt}/cm² out-performed a 0.4 mg_{Pt}/cm² decal cathode.

Future Work

- Continue to prepare and test nanofiber composite membranes with low EW PFSA and polyphenylsulfone using the dual fiber electrospinning approach.
- Prepare and test MEAs with nanofiber network composite membranes containing low EW PFSA.
- Continue to investigate and improve on the performance/properties of electrospun nanofiber fuel cell electrodes.
- Prepare and test a nanofiber MEA (hot-press an electrospun nanofiber anode and cathode onto a nanofiber composite membrane).

RH – relative humidity

FY 2011 Accomplishments

- Fabricated new HPA-based polymers based on two distinct polymer chemistries which are designed to allow the fabrication of films that will be highly proton conducting, durable, cost-effective and have the required mechanical properties of the proton exchange membrane (PEM) fuel cell membrane.
- Showed that the HPA linkages in one of these systems are robust and will survive 10 hours of boiling water.
- Demonstrated that the new polymers systems are able to show proton conductivities as high as the generation I model system films studied previously.

Fiscal Year (FY) 2011 Objectives

- To develop a new class of proton exchange membranes using polymers based on heteropoly acid (HPA) functionalized with organic monomers (polyPOMs).
- To understand the mechanism of proton conduction in the polyPOMs and optimize it for proton conduction under low humidity, higher temperature fuel cell operating conditions.

Technical Barriers

This project addresses the following technical barriers from the Fuel Cells section of the Fuel Cell Technologies Program Multi-Year Research, Development and Demonstration Plan:

- (A) Durability
- (B) Cost
- (C) Performance

Introduction

Currently, fuel cells based on perfluorosulfonic acid (PFSA) PEMs are limited to operating conditions of $\leq 80^{\circ}\text{C}$ and very high inlet RHs, because proton conduction in these materials depends strongly on the presence of water. For automotive applications it is desirable to operate the fuel cell at a temperature of $\leq 120^{\circ}\text{C}$ and low RH to enable the use of existing radiator technology and to eliminate the parasitic loads and system complications associated with externally humidifying the gas streams. Displacement of internal combustion engines by PEM fuel cells would dramatically facilitate the adoption of the H₂ economy and enable a smooth transition from fossil fuels to H₂ produced solely from renewable resources. Materials suitable for use in automotive PEM fuel cells are being developed that have high proton conductivities, $>0.1\text{ S cm}^{-1}$ at 50% RH and operating temperatures of -30 to 120°C , with low area specific resistance, $<0.1\ \Omega\text{cm}^2$. We anticipate that the use of HPAs will generate membranes with oxidative stabilities higher than observed for any PFSA ionomer to date.

Of all the inorganic proton conductors that have been exploited for fuel cell applications HPAs may have the greatest potential as they not only have high proton conductivities, but they have significant synthetic versatility [1]. In previous work (DE-FC02-0CH11088) we have shown that the HPAs have very high proton conductivities at room temperature and can be operated at ambient conditions in a fuel cell using dry gases [2]. Importantly, we demonstrated that some of the protons in HPA have very impressive rates of proton diffusion at elevated temperatures, $>100^{\circ}\text{C}$, under dry conditions. The residual protons in these systems are immobile at elevated temperatures resulting in rather low conductivities. The two key challenges that need to be addressed in practical membranes for fuel cell use, are utilization of all protons under elevated temperature, dry conditions, and immobilization of the water-soluble HPA.

Approach

Our approach is to functionalize HPA with monomers so that they can be fabricated into polymeric materials with the use of a suitable co-monomer. We initially chose to use acrylates as the co-monomers in this project because acrylates represent a polymer system in a kit leaving the synthetic effort to be devoted to making the HPA monomers. This polymer system allowed the chemistry to be easily varied so that the effect of morphology could be studied. In addition as these are free radical polymerizations the materials were obtained easily as films from the polymerization of the cast solutions of co-monomers. We are the first research group to fabricate proton conducting free standing films of these materials, but as they have previously been synthesized as gels [3], we are able to fully disclose our research using this model system. However, the system has certain inherent disadvantages. The acrylate ester linkage is unstable to hydrolysis and the polymers contain readily oxidizable methylene groups. In addition it has been clear the polymers with ≥ 85 wt% of the HPA are unstable to liquid water.

The team assembled includes inorganic and polymer chemists and chemical and materials engineers from both CSM and 3M. CSM and 3M fabricate the HPA monomers, and the extensive knowledge of polymers at 3M is heavily exploited. The polymer system in this project is not restricted, but the mode of proton conduction is mediated by the HPA. In this year's work we have concentrated on making films with two new polymer chemistries so that we can address the additional criteria, such as cost, durability, and mechanical integrity that are need for a practical proton conducting polymer. We have also used nuclear magnetic resonance (NMR) to measure both the self-diffusion coefficient of water and to quantify the amount of water in the polymer. Comparing the NMR data with the proton conductivity data allows us to understand proton transport in these unique systems. We are correlating proton conductivity with morphology as observed by atomic force microscopy and small angle X-ray scattering (SAXS) to enable us to understand structure proton conductivity relationships.

Results

In the final year of this project we down-selected to two practical polymer systems, both based on perfluorinated backbones. The first is based on trifluorovinyl ether (TFVE) monomers that can be thermally polymerized. In Figure 1 we show the general synthetic route to poly TFVE materials with HPA as the protogenic group. A lacunary HPA is functionalized with TFVE moieties via a silane linkage and is then copolymerized thermally with various bi-functional TFVE co-monomers. The polymerization results in a perfluorinated cyclobutane linkage between the co-monomers. As the materials are somewhat brittle we add 10-15 wt% of polyvinylidene fluoride-hexafluoropropylene (PVDF-HFP) so that thin films can be fabricated. The co-monomers consist of biphenyl or phenyl rings bridged by a silane or methylene chains.

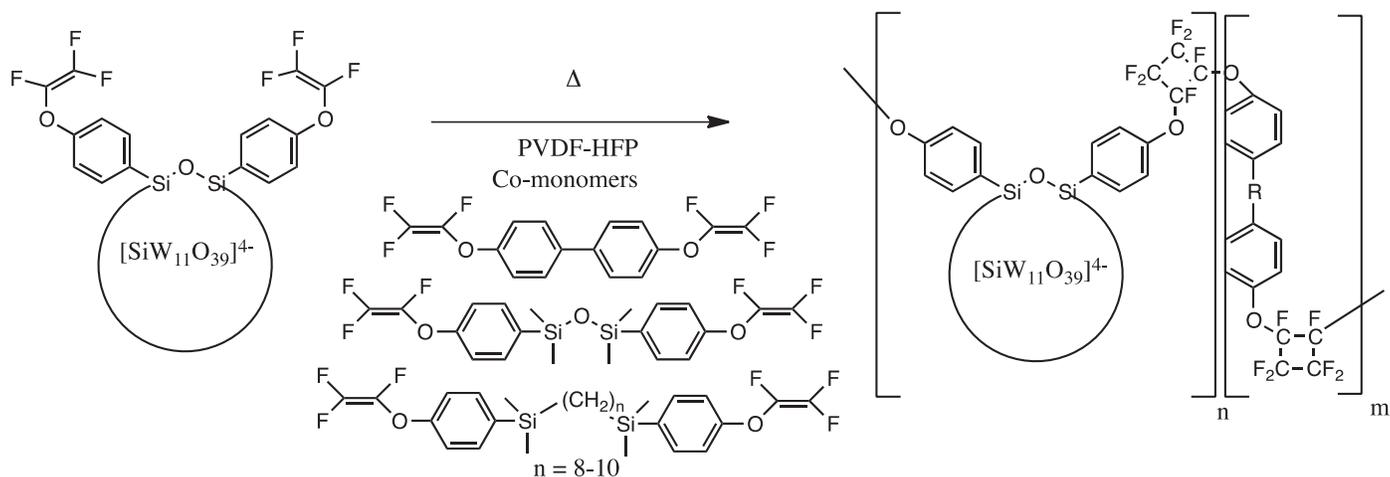

FIGURE 1. General Synthetic Route to Poly Trifluorovinyl Ether (TFVE) Materials with HPA

Pertinent data for these materials is shown in Figure 2. Obviously with four co-monomer and a range of wt% loadings of HPA monomer there is fairly large design space to probe. Our first observation, Figure 2, top left, was that the proton conductivity depended to a large extent on co-monomer chemistry. The homo-polymer, entry 1, even with a very large loading of HPA had negligible conductivity. Materials using the more ridged biphenyl co-monomer and the silicone bridged co-monomer had intermediate conductivity, entries 2 and 3, and the material with the largest conductivity had a long methylene chain incorporated into the polymer backbone. This initial screening pointed us towards further investigation of the co-monomers with methylene chain backbones. Results from this study show a non-linear dependence of proton conductivity with HPA loading, unlike the previously studied acrylate system. In the top right of Figure 2 we show the water uptake and loss during dynamic vapor sorption experiment for an HPA-TFVE polymer co-polymerized with the Si co-monomer. The material shows very little water uptake, but a phase change around 40 wt% water uptake and significant hysteresis on the second wet-up dry-down cycle. In another study involving the C10 methylene co-monomer the phase change is absent but significant water uptake is observed above 90% RH. The SAXS data for both

the C10 and the Si bridged co-monomers are shown in the bottom left of Figure 2. Here we see sharp Bragg peaks in the SAXS at low RH indicating that the phase present under drier conditions is crystalline, as the material becomes wetter the Bragg peaks disappear indicating an amorphous phase. It is this amorphous phase that we believe is strongly proton conducting. Finally in the bottom right of Figure 2 we show a comparison of the wt% water uptake between the 825 equivalent weight (EW) 3M ionomer our generation I polyPOM85v acrylate material and an HPA-TFVE material. It should be noted that the water uptake of the HPA proton conductors is much smaller than for the PFSA material and is 10 times lower for the HPA-TFVR polymer than for the PFSA material.

The second polymer investigated was a functionalized Dyneon™ polymer developed at 3M. In Figure 3 we show the general synthetic route to these polymers. First the polymer is dehydrofluorinated and functionalized with bromophenyl ether. The polymer is then phosphonated and hydrolyzed so that a lacunary HPA can be attached. Note that it takes two attachment points to attach one HPA moiety. We believe that HPA only attached to one are not immobilized, and thus, future work will be directed towards double attachment points for all HPA in the film. We discovered that for these materials the method of film

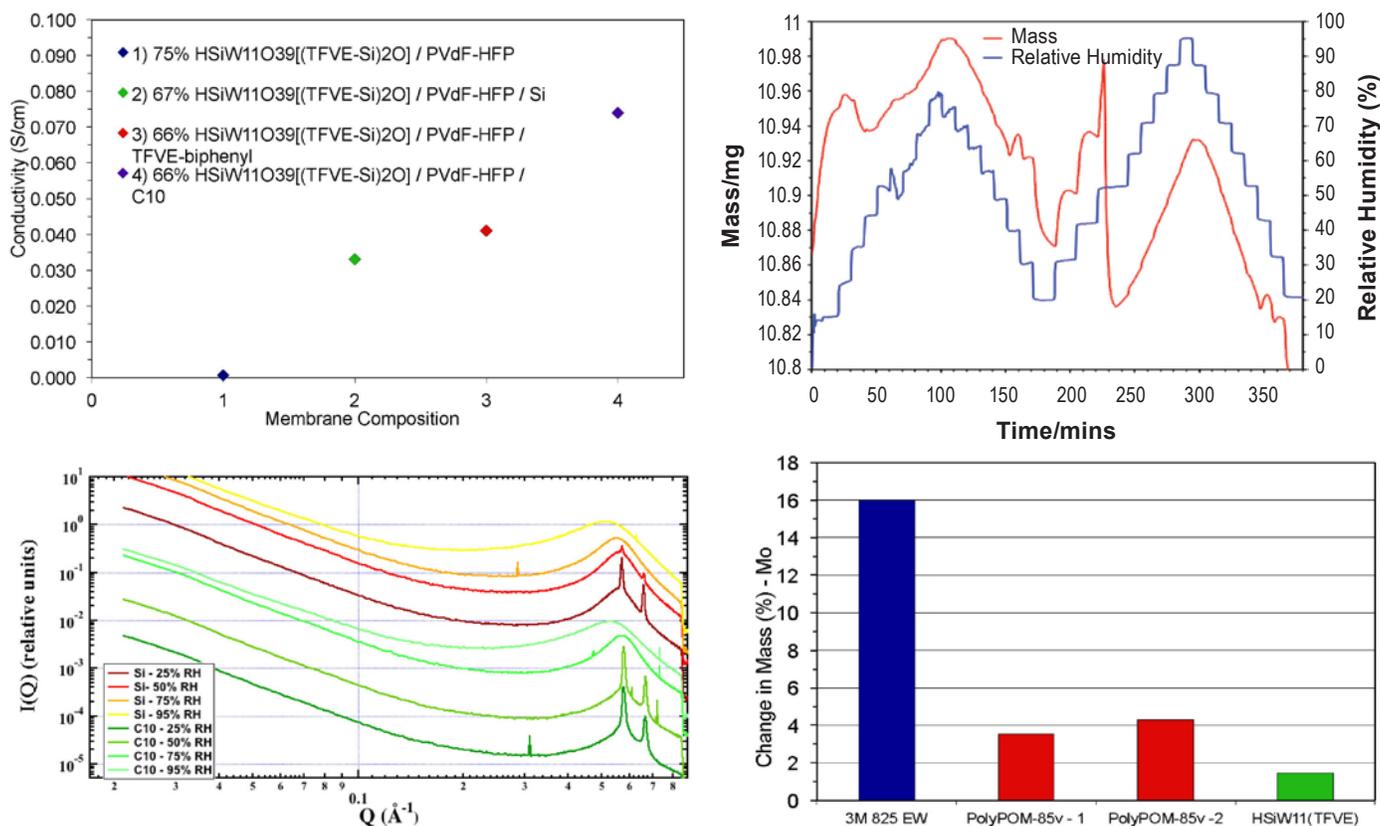

FIGURE 2. Top left, proton conductivity for TFVE polymers with differing co-monomers at 80°C and 80% RH. Top right, dynamic vapor sorption data for a TFVE polymer containing the Si co-monomer. Bottom left, SAXS data for a TFVE polymer with a C10 co-monomer and a Si co-monomer. Bottom right, comparison of wt% water uptake for the 3M 825 EW ionomer, the polyPOM85vinyl acrylate materials and a TFVE polymer with a Si co-monomer.

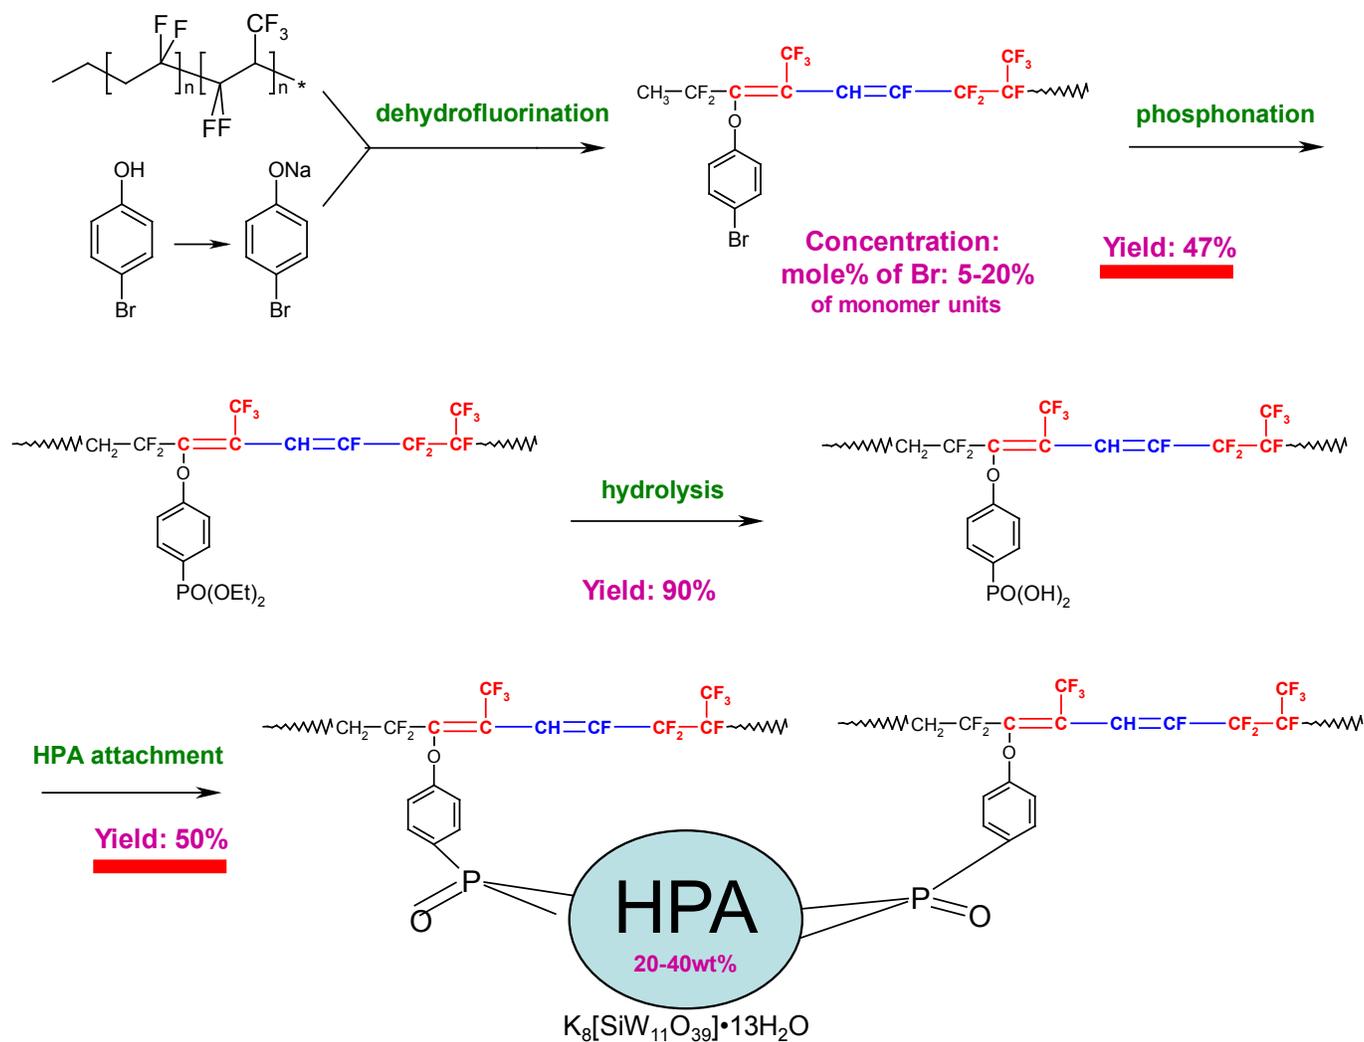

FIGURE 3. General Scheme Showing Functionalization of Dyneon™ Polymer with HPA Moieties

processing is extremely important. In Figure 4, left we show proton conductivity data comparing the HPA functionalized Dyneon™ polymer prepared with differing dissolution times on different liners with the 825EW 3M PFSA ionomer. Interestingly it was the material that was not fully dissolved when cast that gave the best proton conductivity. The material that was fully dissolved reorganized on casting to give dramatically poorer performance. We also compare the stress strain curves for the HPA functionalized Dyneon™ polymer, the 825 EW 3M PFSA ionomer, and our generation I polyPOM85v acrylate polymer. It can be seen that the Dyneon™-based film is much stronger than either the 3M ionomer or the generation I film.

Conclusions and Future Directions

- We have functionalized two different perfluorinated polymer systems with HPA that will ultimately lead to

practical polymer systems for fuel cells run under hotter and drier conditions.

- The new polymers have very little water uptake and appear to be stronger than conventional ionomers.
- Although this project is ending, future work will focus on more robust HPA attachment and optimization of the films to meet all DOE targets for membranes.

Contract Number: 36-06GO16033

Start Date: June 1, 2006

Projected End Date: February 29, 2012

Technical Targets

This project is developing a multi-component composite (mC^2) membrane to meet the following DOE 2015 technical targets for membranes:

- Membrane Conductivity: At $\leq 120^\circ\text{C}$: 0.1 S/cm; at room temperature: 0.07 S/cm; at -20°C : 0.01 S/cm
- Membrane ASR: 0.02 Ωcm^2

FY 2011 Accomplishments

- Conductivity: Met DOE conductivity targets with polymer membrane and composite membrane: target of 0.1 S/cm (achieved >0.1 S/cm).
- ASR: Met DOE membrane ASR target: 0.02 Ωcm^2 (achieved 0.02 Ωcm^2).
- Cross-over: Met DOE hydrogen cross-over target: 2 mA/cm² (achieved 0.48 mA/cm²).
- Polymer Development: Prepared chemically stabilized low EW co-polymer with increased molecular weight (for greater mechanical strength and durability).
- Additive Development: Synthesized zeolite with a mean particle size reduced by $>60\%$ (30 nm compared to previously 80 nm) for improved dispersion and greater uniformity of ion-conducting clusters.
- Composite Membrane Fabrication: Integrated lower-cost protonic conductivity enhancer with 80% higher density of mobile protons.
- Membrane Electrode Assembly (MEA) Fabrication:
 - Improved process conditions for lower-EW polymer in collaboration with the University of Central Florida (UCF).
 - Fabricated more than half a dozen MEAs of up to 25 cm² active area for characterization testing (UCF).
- MEA Testing: MEA with 5% lower EW, chemically stabilized polymer in the electrodes comprehensively tested by UCF in 11-day cell test (DOE protocol).

Fiscal Year (FY) 2011 Objectives

- Develop humidity-independent, thermally stable, low equivalent weight (EW) composite membranes with controlled ion-cluster morphology, to provide high proton-conductivity at up to 120°C (overall goal: meet DOE 2015 targets).
- Improve mechanical properties to significantly increase the durability and reduce the gas cross-over.
- Reduce the membrane area specific resistance (ASR) to increase cell performance and lower the capital and operating costs.

Technical Barriers

This project addresses the following technical barriers from the Fuel Cells section of the Multi-Year Research, Development and Demonstration Plan [1] of the DOE Fuel Cell Technologies Program:

- (A) Durability
- (B) Cost
- (C) Performance

Introduction

This project is focused on the development of composite proton exchange membranes (PEMs) that can operate at low relative humidity (RH) and over a wide temperature range (-20 to 120°C). Their main application is in transportation fuel cells. In addition, FCE is considering use of these membranes for co-production of hydrogen from high-temperature fuel cells. The higher operating temperature

imparts improved tolerance to impurities, such as carbon monoxide, thereby increasing the co-production efficiency and simplifying the system.

The goal is to develop a structure in which ion-conducting clusters remain intact at low RH. A major challenge is that current proton conducting polymers cannot sufficiently hold on to water under these conditions. Since the conduction mechanism relies on movement of hydrated species, the conducting path is compromised, resulting in low performance. Membranes that can operate at lower RH at elevated temperatures up to 120°C will reduce the fuel cell system complexity and cost. This project is developing a composite membrane, in which both the ionic conductivity and mechanical properties are enhanced to meet DOE's 2015 goals for transportation fuel cells.

Approach

The approach to address each of the DOE target parameters is summarized in Table 1. The emphasis in the past year has been to integrate a lower-cost protonic conductivity enhancer (di-valent superacid) into the composite membrane.

TABLE 1. Approach for the Composite Membrane

Target Parameter	DOE Target (2015)	Approach
Conductivity at: $\leq 120^{\circ}\text{C}$	0.1 S/cm	Multi-component composite structure, lower EW, additives with highly mobile protons
Conductivity at: Room Temp.	0.07 S/cm	Higher number of functional groups
Conductivity at: -20°C	0.01 S/cm	Stabilized nano-additives
Inlet water vapor partial pressure	< 1.5 kPa	Immobilized cluster structure
Hydrogen and oxygen cross-over at 1 atm	2 mA/cm ²	Stronger membrane structure; functionalized additives
Area specific resistance	0.02 Ωcm^2	Improved bonding capability for MEA
Cost	20 \$/m ²	Simplified polymer processing
Durability with cycling	5,000 hours	Thermo-mechanically compliant bonds, higher glass transition temp.
Unassisted start from low temp.	-40°C	Stabilized cluster structure design

Results

This year's efforts were focused on improving the performance and durability of the mC² membrane. The efforts were centered on improving the following mC² components:

- Co-polymer

- Water retention additive
- Protonic conductivity enhancer

The co-polymer provides the basic building block for the membrane. It is an advanced perfluoro sulfonic acid polymer (PFSA) with a short side chain. It has a higher density of functional groups (lower EW) compared to long side chain polymers, such as Nafion[®]. The lower EW leads to significantly higher proton conductivity. It comes without a reduction in mechanical strength, due to a higher crystallinity of the short side chain PFSA. Grades with higher molecular weight have been synthesized. This leads to greater polymer chain entanglement and therefore better mechanical properties. The higher molecular weight has the added benefit of improving the film forming properties of the polymer dispersion.

The membrane additives are designed to retain water at the low RH conditions and to enhance the composite membrane's proton conductivity by providing an alternate proton conduction path [2]. This path is designed to efficiently transport protons at high temperature as well as subfreezing conditions. Zeolite nanoparticles have been developed to retain water in the membrane. They have a high water uptake capacity without dimensional change, since the water is contained within the three-dimensional tunnel structure. Zeolite synthesis was improved, resulting in a reduction in mean particle size from about 80 nm to about 30 nm. The desired crystalline cuboidal structure of the particles was confirmed by transmission electron microscope (TEM) analysis, as shown in Figure 1. The analysis also confirmed a particle size of predominantly 20-50 nm. The TEM analysis was kindly provided by the Microscopy Group at Oak Ridge National Laboratory. Stability of the zeolite particles was analyzed by dynamic light scattering. Figure 2 shows a mean particle size of 33 nm, measured one year after zeolite synthesis.

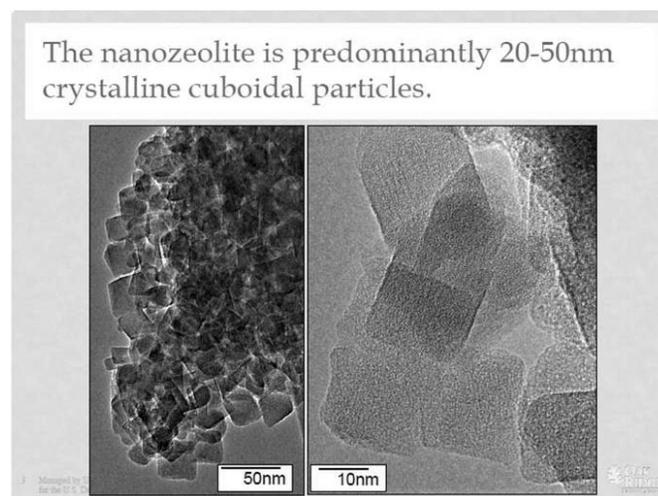

FIGURE 1. Transmission Electron Microscopy of Zeolite Particles used as Water Retention Additive in mC²

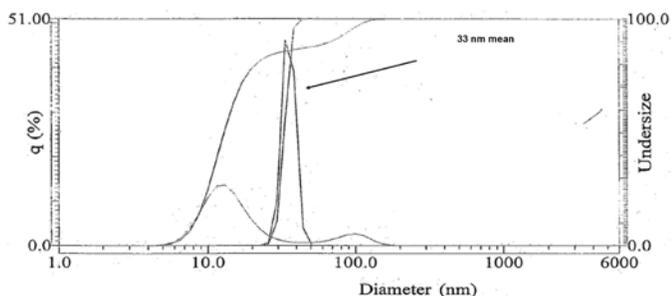

FIGURE 2. Demonstrated Long-Term (1 Year) Zeolite Particle Size Stability

To enhance the proton conductivity of the membrane, a novel superacid, developed in the previous year, was utilized in the mC² membrane. It has 80% greater density of highly mobile protons, to increase the transfer rate of protons through the membrane at all operating conditions.

MEA Fabrication and Testing: Membrane samples were supplied to UCF for characterization and MEA fabrication. UCF has been tasked by DOE to fabricate MEAs using membrane samples supplied by FCE, to independently validate their performance. A modified MEA fabrication process was developed, in order to ensure integrity of mC² membrane components. Using this process, several MEAs were fabricated by UCF, including B2, B3 and B7. Cell performance results of these MEAs at 120°C and low RH (35%) are shown in Figure 3. MEAs B2 and B3, made with short-side chain ionomer in the electrodes, had higher performance compared to a Nafion[®] reference MEA at practical current densities (300-1,000 mA/cm²). As expected, B2 and B3 had significantly lower cell resistance than the Nafion[®]-based MEA. B7 used a different ionomer in the electrodes. Compared to B2 and B3, it has 5% lower EW and is chemically stabilized. To better understand the performance of B7, a detailed performance analysis was carried out by UCF. It uses a method developed at the University of Connecticut [3] to calculate contributions of activation, membrane, electrode

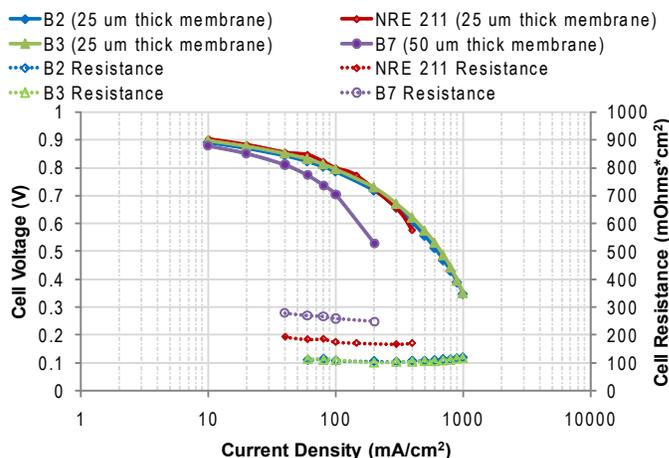

FIGURE 3. Cell Performance at 120°C: B2 and B3 have Lower Cell Resistance than NRE211

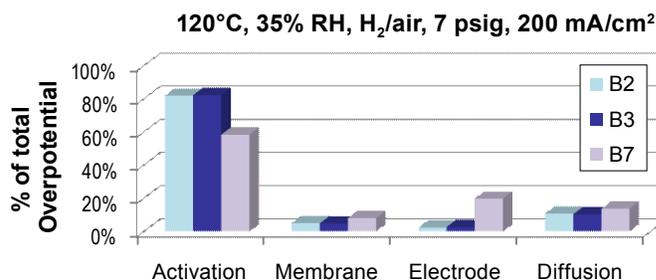

FIGURE 4. Fuel Cell Performance Analysis of Three Different MEAs

and diffusion to the cell's overpotential. Data at 120°C and 35% RH, shown in Figure 4, indicates that B7 has increased electrode and diffusion resistance. This suggests a need to optimize the electrodes when using the lower EW, chemically stabilized ionomer. A study to look at the effect of ionomer content in the electrodes is underway at UCF.

TABLE 2. MEA Test Results Compared to DOE 2015 Targets

Characteristic	Units	Target 2015	B1	B2	B3	B7	NRE 211
Area specific proton resistance ^c at:							
120°C and 70 kPa water partial pressure	Ohm cm ²	≤ 0.02	not determined	0.08	0.08	0.23	0.15
80°C and 38 kPa water partial pressure	Ohm cm ²	≤ 0.02	not determined	0.02	0.02	0.05	0.02
Maximum Hydrogen cross-over ^a	mA / cm ²	2	not determined	1	0.95	0.48	0.76
Minimum electrical resistance ^b	Ohm cm ²	1,000	not determined	1,200	800	500	2100
Performance @ 0.8V (¼ Power)	mA / cm ²	300	not determined	104	177	150	113
	mW / cm ²	250	not determined	84	142	120	91
Performance @ rated power	mW / cm ²	1,000	not determined	334	567	482	363

* Values are at 80°C unless otherwise noted

^a Measure in humidified H₂/N₂ at 25°C

^b Measure in humidified H₂/N₂ using linear sweep voltammetry curve from 0.4 to 0.6 V at 80°C

^c Determined by subtracting contact resistances from cell current interrupt values

All three MEAs tested by UCF (B2, B3, B7) passed comprehensive 11-day tests at UCF (per DOE-approved protocol). B7, which utilized chemically stabilized polymer, had the lowest hydrogen cross-over at the end of the test with 0.5 mA/cm². This is well below the DOE 2015 target of 2 mA/cm². UCF post-test analysis showed good integrity of the MEA; no pinholes were detected.

A comparison of the performance of the MEAs to the DOE 2015 targets is shown in Table 2. The parameters that already meet the DOE 2015 targets are highlighted in green. The remaining parameters show good progress towards the DOE targets (highlighted in yellow).

Conclusions and Future Direction

A mC² membrane design for high temperature and low RH operation has been implemented to fabricate membranes with enhanced performance at the DOE target conditions (Table 1). Accomplishments include:

- Synthesized water retaining additive (zeolite) with 60% lower particle size (Figure 1).
- Validated long-term particle size stability (Figure 2).
- Demonstrated significantly lower cell resistance of MEAs made with the advanced materials (Figure 3) meeting the DOE ASR target at 80°C (Table 2).
- Met the DOE hydrogen cross-over and electrical resistance targets (Table 2).
- Identified a need for electrode optimization using the improved ionomer (Figure 4).

In the remaining months of the current project we will continue the composite membrane development, with an emphasis on meeting the remaining DOE target parameters (highlighted in yellow in Table 2).

Fiscal Year (FY) 2011 Objectives

To pack more membrane active area into a given geometric plate area. Thereby allowing both targets of power density and platinum utilization to be achieved:

- To demonstrate a fuel cell single cell (50 cm²) with a 2-fold increase in the membrane active area over the geometric area of the cell by corrugating the membrane electrode assembly (MEA) structure.
- Incorporation of an ultra-low Pt-loaded corrugated MEA structure in a 50 cm² single cell that achieves the DOE 2015 target of 0.2 gram Pt/kW, while simultaneously reaching the targets of power density:
 - 1 W/cm² at full power
 - 0.25 W/cm² at 1/4 power

Technical Barriers

This project addresses the following technical barriers from the Fuel Cells section of the Fuel Cell Technologies Program Multi-Year Research, Development and Demonstration Plan:

- Cost (lower cost metal gas diffusion layer [GDL], lower plate/GDL manufacturing costs)
- Performance (high power density with low Pt-loaded MEAs)

Introduction

The traditional proton exchange membrane (PEM) fuel cell stack with its bipolar plates, MEAs, seals and end-plates has been the dominant method of construction of multi-kW fuel cells for the past 40 years. Smaller sub-watt and portable applications have explored novel cell design variations such as “jelly roll” concepts but none have been able to achieve the power density of the traditional stacked plate design.

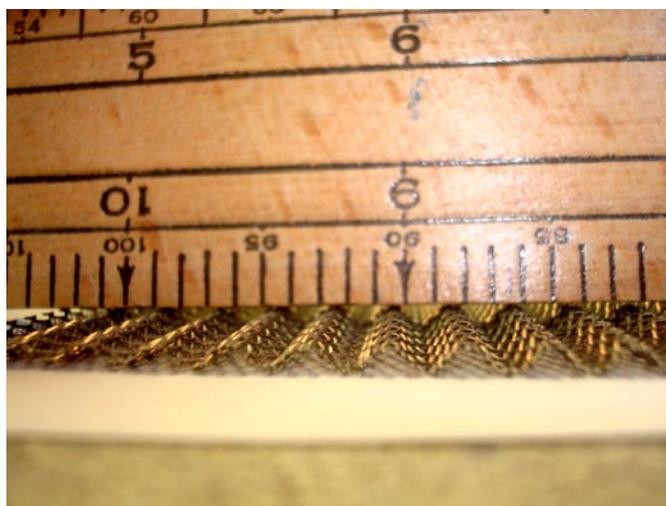

FIGURE 1. Titanium Screen as a Gas Diffusion Layer

FIGURE 2. Corrugated Gas Diffusion Layer Structure

The primary reason for this is the efficient collection of the current and the compact packing of the MEAs.

Approach

At the present time one of the most challenging aspects of traditional PEM fuel cell stacks is the difficulty to achieve the platinum catalyst utilization target of 0.2 g Pt/kWe set forth by DOE [1,2]. Good catalyst utilization can be achieved with state-of-the-art CCMs when ultra-low catalyst loadings (<0.1 mg/cm²) are used at lower current. Unfortunately when ultra-low loadings are used, the peak power density is lower as compared to conventional loadings [3]. Thus, a larger total active area and a larger bipolar plate are needed, which results in a lower overall stack power density. Therefore, this project aims to realize both the Pt utilization targets as well as the power density targets of the DOE by corrugating the fuel cell membrane electrode structure and thus packing more membrane area into the same geometric plate footprint.

A single cell 50 cm² fuel cell test jig (or fixture) will be designed and fabricated such that it will allow testing of both conventional flat MEAs with conventional flow fields and the corrugated single-cell assemblies fabricated. Furthermore, the jig will also allow the hand assembly of each of the individual components. Inserts will be created to generate straight through flow and serpentine flow in both flat and corrugated MEA architectures so that water, thermal and gas flow management issues can be diagnosed.

Results

Results to date show that expanded titanium metal screens can be formed into corrugated structures and incorporated into an operating fuel cell. Electrical resistance of the diffusion material was measured and found to be reduced as a result of the new diffusion material. However, mass transport and water management issues were negatively impacting the results of the tests. These issues are mainly being attributed to gas flow by-passing the corrugated channels, and the large pore size of the GDLs being used. We plan to address these issues by developing more conventional GDLs in the corrugated format that contain the commonly used carbon black/poly-tetrafluoroethylene micro-diffusion layers up against the membrane to form a very fine pore structure interface to the membrane. This is the structure of the current state-of-the-art GDLs that have the proper water-management and mass-transport requirements for high performance MEAs.

Conclusions and Future Directions

In summary, success has been made in expanded metal screen structures both in cell performance and in structures.

Future work will include: get single cell test fixture working; get corrugated Ti expanded screen GDL attached to Ti plate; demonstrate low contact resistance and good mass transport in flat Ti screen structures; and get mechanical strength modeling effort underway.

Contract Number: DE-FC36-06GO16028

Subcontractors:

- BekkTech LLC, Loveland, CO
- Scribner Associates, Inc., Southern Pines, NC

Project Start Date: April 1, 2006
 Project End Date: September 30, 2011

Fiscal Year (FY) 2011 Objectives

- Fabricate membrane electrode assemblies (MEAs) from team membranes.
- Test team MEAs for fuel cell performance.
- Standardize methodologies for in-plane and through-plane membrane conductivity measurements.
- Provide High Temperature Membrane Working Group (HTMWG) members with standardized tests and methodologies.
- Organize HTMWG bi-annual meetings.

Technical Barriers

This project addresses the following technical barriers from the Fuel Cells section (3.4) of the Fuel Cell Technologies Program Multi-Year Research, Development and Demonstration Plan:

- (A) Durability
- (C) Performance

Technical Targets

FSEC plays a supporting role to the five teams who are tasked with developing an improved high temperature, low relative humidity membrane for proton exchange membrane fuel cells (PEMFCs). FSEC has developed standardized experimental methodologies to: (1) measure conductivity (in-plane and through-plane); (2) characterize mechanical, mass transport and surface properties of the membranes as working membrane electrode assemblies; and (3) predict durability of the membranes and their membrane electrode assemblies.

This project manufactures, tests and evaluates MEAs for performance and stability. Test results were evaluated against DOE's 2015 membrane targets as shown in Table 1 (A, B and D identify the teams and the numbers are those assigned by FSEC to identify a specific sample).

^bMeasured in humidified H₂/N₂ using linear sweep voltammetry curve from 0.4 to 0.6 V at 80°C

FY 2011 Accomplishments

- Performed conductivity testing on baseline membranes from Giner, Inc. and FuelCell Energy (FCE), and prepared and tested MEAs from these membranes.
- Assisted Case Western Reserve with membrane casting and cross-linking.
- Prepared and tested MEAs from Case Western Reserve University membranes.

- Developed and verified a new method for determining location of crossover in MEAs.
- Established procedures for preparing transmission electron microscopy (TEM) samples and examined samples via TEM.
- Performed stress-strain experiments on several team member samples.
- Completed a study to determine the effect of cell pressure on performance.
- Performed durability test for sample from Giner.
- Collaborated with FCE to optimize ionomer loading in catalyst ink.
- Completed milestone “Define correlation between membrane/MEA degradation rate from accelerated testing and lifetime.”

Introduction

Generally, two regimes of PEMFC operation exist: the typical operating temperatures between 60–80°C, and elevated temperatures higher than 100°C. At higher temperatures, heat is more easily rejected from the cell stack, anode catalyst poisoning by CO is less important, water transport is simplified, the kinetics of fuel oxidation will be improved, and gas transport and the efficiency of the cell will be enhanced. However, operation of PEMFCs at high temperature and ambient pressure results in decreased relative humidity, which significantly increases membrane resistance, thus decreasing cell performance. This has driven the need for development of high-temperature membranes and membrane electrode assemblies that could operate at temperatures of up to 120°C, low relative humidity (RH) and near atmospheric pressure.

The objective of this phase of the project has been to fabricate and test MEAs from fuel cell membrane materials that meet the goals outlined by the DOE in the multi-year plan. Specific goals are: operation at elevated temperatures (up to 120°C), with a demonstrated area specific resistance of <0.02 Ohm cm² at 120°C and 40 kPa inlet water vapor partial pressure to the fuel cell stack (85% RH measured at 80°C).

Approach

The High Temperature, Low Relative Humidity Membrane program includes five teams, each of which is skilled in producing novel membranes expected to meet the goals of the program. Some of these teams are not necessarily skilled in the ability to produce an MEA, or to test the MEAs in a fuel cell. FSEC’s objective is to provide the expertise to fabricate MEAs, and assemble cells to test the membranes under fuel cell conditions. FSEC has worked closely with the membrane manufacturers to develop appropriate methods for manufacture of the MEA

and to test the MEAs according to a process data base that has been developed at FSEC. This approach involves a detailed logic flow chart that itemizes each step of the manufacture, fuel cell testing and post test analysis of the MEA. Each membrane manufacturer approves the steps of the logic flow chart in advance of the process. Furthermore, FSEC iterates with the teams to optimize the results.

Results

The program began five years ago with 11 teams initially funded to develop high conductivity membranes. After the Go/No-Go decision point, six teams were selected to continue and an additional one was discontinued this year. Over the course of the program, conductivity, stability and performance improved. Many membranes have shown promise. The collaboration between FSEC and the teams guided catalyst-coated membrane (CCM) development, and the program is proving to be an excellent model for future DOE membrane and MEA development projects.

Significant progress toward achieving DOE targets was made over the last five years as shown in Tables 2, 3, and 4 for three of the teams.

^aMeasured in humidified H₂/N₂ at 25°C

^bMeasured in humidified H₂/N₂ using linear sweep voltammetry curve from 0.4 to 0.6 V at 80°C

N/D - not determined

In addition to the results for the samples from the teams shown in the tables, samples were received from Colorado School of Mines (CSM) and from Vanderbilt University. Difficulties were encountered with the CSM membranes because stickiness resulting from the Florida humidity made them hard to handle. No successful MEAs were fabricated. Two Vanderbilt membranes were received and MEAs constructed and tested. Data was not analyzed in time for this report.

Conclusions and Future Directions

- Eleven teams were initially funded to develop high conductivity membranes.
- Six teams were selected to continue after Go/No-Go, five continuing this year.
- Conductivity, stability and performance improved over course of program.
- Many membranes have shown promise and should be pursued.
- Collaboration between FSEC and teams guided CCM development.
- This project is an excellent model for future DOE membrane development projects.
- Significant progress was made toward developing membrane suitable for fuel cell use.
- In the future, FSEC will continue to work closely with team members, preparing and testing MEAs in fuel cell hardware.

- Additional support will be provided to FCE for electrode optimization.
- FSEC will continue to work closely with Case Western Reserve University to reduce cross-over.
- FSEC is preparing procedures for testing cross-over and electrical resistance that follow DOE guidelines.

Subcontractors and Federally Funded Research and Development Centers:

- Jeff Dahn, David Stevens, Dalhousie University, Halifax, Nova Scotia, Canada
- V. Stamenkovic, Dennis van der Vliet, Nenad Markovic, Argonne National Laboratory (ANL), Argonne, IL
- Charles Hays, Jet Propulsion Laboratory (JPL), Pasadena, CA

Project Start Date: April 1, 2007

Projected End Date: December 31, 2011

- high prospects for 40,000 hours durability under operating conditions for stationary applications, and
- high volume manufacturability.

Technical Barriers

This project addresses the following technical barriers from the Fuel Cells section of the Fuel Cell Technologies Program Multi-Year Research, Development and Demonstration Plan:

- (A) Durability
- (B) Cost
- (C) Performance
- (D) Water Transport within the Stack

Technical Targets

This project is focused on improving the performance and durability of the 3M nanostructured thin film (NSTF) roll-good fabricated electrocatalysts and MEAs. Table 1 compares the NSTF current 2nd quarter, calendar year (CY) 2011 status with DOE electrocatalyst targets for 2010/2015 updated from Table 3.4.12 of the DOE Fuel Cell Technologies Program Multi-Year Research, Development and Demonstration Plan to reflect recent accelerated durability test results. The MEAs used for the inverse specific power density values listed in the first row, PGM total content, had PtCoMn catalysts with loadings of 0.05/0.10 mg_{PGM}/cm² on the anode and cathode, respectively deposited by 3M's standard P4 process. The short stack results were obtained outside the project but evaluated catalysts and gas diffusion layers (GDLs) developed within the project. The updated accelerated stress test results were obtained with PtCoMn catalysts containing 0.05 mg_{Pt}/cm² on the anode and 0.15 mg_{PGM}/cm² on the cathode deposited by the new P1 process discussed in the following.

Fiscal Year (FY) 2011 Objectives

The objectives of this project are development of a durable, low cost (both precious group metal [PGM] content and manufacturability), high performance cathode electrode (catalyst and support), which is fully integrated into a proton exchange membrane (PEM) electrode assembly (MEA) characterized by:

- total Pt group metal loading per MEA of ≤ 0.25 mg/cm²,
- short-stack specific power density of ≤ 0.3 g/kW at rated power,
- durability sufficient to operate at $>80^\circ\text{C}$ for 2,000 hours, $\leq 80^\circ\text{C}$ for 5,000 hours, with cycling for transportation applications,

FY 2011 Accomplishments

Water Management for Cool/Wet Operation (Task 5.2)

- Developed key strategy for reducing cathode flooding at cool temperatures by taking product water out the anode, the "water-out-anode" mode.
 - Demonstrated that anode GDL was most critical component for water-out-anode strategy. Significantly improved cool/wet performance at ambient pressure.
 - Developed cathode gradient catalyst hybrid construction that also dramatically helps water management at low temperature as well as high temperature.

TABLE 1. Progress towards Meeting Technical Targets for Electrocatalysts and MEAs for Transportation Applications. Values in blue are new DOE targets this year.

Characteristic	Units	Targets 2015	Status: Values for roll-good CCM w/ 0.15mg _{Pt} /cm ² per MEA or as stated

RH – relative humidity; ECSA – electrochemical surface area ; OEM - original equipment manufacturer; EW - equivalent weight; CCM - catalyst coated membrane; GM - General Motors; OCV - open circuit voltage

New Catalyst Activity and Understanding; Annealing and Process Scale-Up (Task 1.3)

- Extended enhanced catalyst deposition process improvement (P1) from pure Pt to PtCoMn and obtained same dramatic gains in Pt(hkl) grain size and surface smoothing with simpler, more cost-effective coating process.
- Scaled up Surface Energy Treatment (SET) process for roll-to-roll catalyst annealing. Significantly improves oxygen reduction reaction (ORR) activity of some alloys, more than others.
- Demonstrated Pt₃Ni₇ alloy catalyst mass activities in 50 cm² cells ranging from 0.35 ± 0.06 A/mg to 0.59 ± 0.08 A/mg at 3M and GM depending on lab, protocol and loading measurement. Gain in ORR activity derived from SET catalyst annealing process.
- Validated Pt₃Ni₇ alloy peak composition in compositional spread rotating disk electrode (RDE) measurements on NSTF whiskers (Dalhousie).
- Obtained first confirmation of Pt₃Ni₇ composition at nm scale of whiskerettes and Pt enrichment of whiskerette tips (JPL).

Catalyst and MEA Durability with Preliminary 2010 “Best of Class MEAs” (Task 2)

- OCV Hold: Demonstrated 12 ± 5% OCV voltage loss after 1,400 hours at 250/200 kPa H₂/air, 90°C, 30%RH, and met cross-over targets.
- 1.2 V hold: Demonstrated 10 mV loss at 1.5 A/cm², 10% loss of ECSA and 10% loss of mass activity after 400 hr at 1.2 V at 80°C, 150 kPa, 100% RH.
- 30,000 Cyclic Voltammetry (CV) cycles: Demonstrated 40 mV loss at 1.5 A/cm², 18% loss of ECSA, and 48% loss of mass activity under 30,000, 0.6-1.0-0.6 V cycles at 50 mV/sec and 80/80/80°C.
- Demonstrated load cycling lifetimes of 9,000 hours with 2009 “Best of Class” catalyst loadings (0.05/0.10 mg/cm²) in non-supported 3M PEM with chemical stabilizers.

Membrane-Electrode Integration and CCM Scale Up (Task 5.1)

- Produced 50,000 linear ft combined of NSTF substrate, coated catalyst supports, and CCM for process development, qualification and customer use.

2010 “Best of Class” MEA Down-Selection for Final Stack Testing (Task 5.3)

- Defined and implemented major screening programs for down-selection and integration of all MEA components for 2010 best of class MEA for final stack testing.
- Final short stack testing activities initiated at GM.

Introduction

State-of-the-art PEM fuel cell electrocatalyst technology utilized in today’s prototype fuel cell vehicles reveals limitations with respect to general durability and robustness under start-stop cycling, adequate performance with low PGM loadings, and low cost manufacturability. To a large degree, these deficiencies are traceable to properties of the conventional carbon supported dispersed Pt catalysts in use today. The research and development of this contract are focused on overcoming these three most critical barriers for fuel cell MEA automotive deployment by using an alternative catalyst support and deposition method.

Approach

The approach to achieve the above objectives builds on a 14-year DOE/3M funded development of the 3M NSTF catalyst and MEA technology. The NSTF catalyst fundamentally has higher specific activity for oxygen reduction [1-8], removes all durability issues with carbon supports, demonstrates much lower losses due to Pt dissolution and membrane chemical attack [9-12], and has significant high volume all-dry roll-good manufacturing advantages [13].

The scope of work in the previous three-year 1st budget period included extensive work at 3M to increase the NSTF catalyst support film surface area, fabrication and screening of new alloys in 50 cm² single cells, and evaluation of multiple deposition parameters to obtain increased catalyst surface area and utilization. Complementary to this work at 3M, collaborative work included high throughput fabrication and characterization of new multi-element Pt alloys (ternaries and quaternaries) with Dalhousie University, fundamental catalyst characterization studies with ANL, and development and evaluation of a pseudo-RDE catalyst evaluation technique with JPL. Research during the fourth year has focused at 3M on: a) continued water management improvements for cool/wet operation via optimization of materials, electrode structure and operating conditions; b) catalyst fabrication process improvements for increased catalyst performance and production efficiency; c) in-depth MEA component screening to down-select final configurations for the final short-stack testing; d) continued accelerated testing to benchmark the NSTF-MEA durability with each generation of MEA components; and e) fabrication of roll-good materials for stack testing by the GM fuel cell laboratory.

Results

The technical accomplishments for the fourth year fall roughly into five areas of research and development corresponding to Project Tasks 1, 2, 5.1, 5.2 and 5.3. We briefly summarize the main results from each of these areas.

Task 1

The NSTF-Pt₆₈Co₂₉Mn₃ catalyst has been the workhorse cathode and anode of choice for a number of years. With it we have been able to exceed the previous DOE 2015 target of 0.2 g-Pt/kW in a full size short stack with 0.05 mg/cm² of PGM on the anode and 0.1 mg/cm² on the cathode [14]. More recent work has focused on improving the NSTF-PtCoMn roll-to-roll process so that the support whiskers and sputter deposited catalyst alloy can be applied simultaneously on the moving substrate web in a single step. This new process, called P1, offers greater simplicity and more cost-effective coating than the standard process called P4. The key is to make sure it does not reduce performance and hopefully improves it. An example of its effectiveness is shown in a series of PtCoMn loadings deposited by the P1 process at 0.054, 0.103, 0.146 and 0.184 mg_{Pt}/cm². They were coated in the production equipment and evaluated for structural differences by X-ray diffraction (XRD), scanning electron microscopy (SEM)/transmission electron microscopy (TEM) and fuel cell performance. SEM indicated no substantial differences at 40,000 magnification, but the TEM and XRD results showed significant changes. Figure 1(a) (left) shows that whereas the face-centered cubic (fcc) Pt[hkl] grain sizes by the standard process P4 are essentially independent of loading and 4 to 6 nm in size, the P1 process produces grain sizes that increase with loading and are larger, 6 to 12 nm. Consistent with this are the TEM images, Figure 1(a) (right), that show the catalyst coatings on the whiskers are smoother than those obtained by the P4 process, which produces highly oriented whiskerettes growing off the sides of the underlying whisker core, as discussed at length in reference [15]. This can be understood since aspects of the P1 process provide annealing like conditions.

Fuel cell performance of the P1 deposited PtCoMn is also generally the same as with the P4 process, as shown in Figure 1(b). With the conditions shown in the inset of Figure 1(b), in the same 50 cm² cell with quad-serpentine flow fields, using the same station and production lots of PEMs and GDLs, the P1 processed anodes and cathodes (0.1 to 0.184 loadings) show very similar performance to each other and to P4 processed 0.10 mg_{Pt}/cm² PtCoMn cathode. The galvanodynamic scans with the 0.054 mg/cm² cathodes are substantially lower (black open and closed squares) but at least as good if not better than historical results with P4 cathodes at these loadings. More careful inspection of the curves in Figure 1(b), show the P1 process yields about a 10 mV improvement at 0.32 A/cm² and 5 mV at 1 A/cm² over the P4 process, but very similar performance

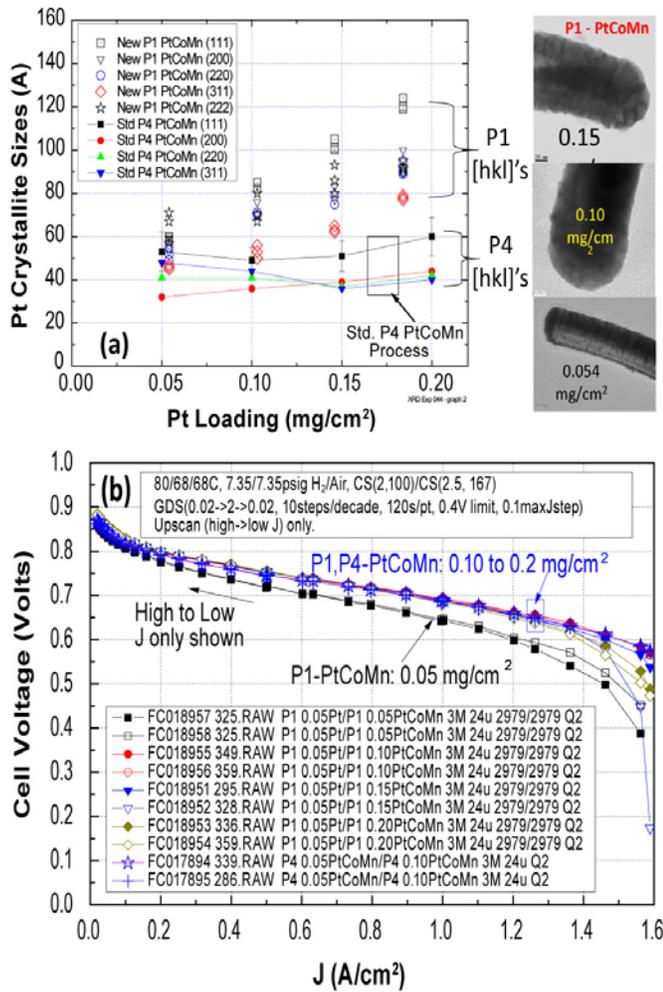

FIGURE 1. (a) Left: PtCoMn fcc[hkl] grain sizes by XRD as a function of Pt loading for catalysts sputter coated by new process P1 versus the standard process P4. Right: TEM images of the PtCoMn coated whiskers using new deposition process P1. At all three loadings the catalyst coating is smoother than by the standard P4 process that produces whiskerettes as discussed in reference [15]. (b) Polarization curves for PtCoMn deposited by the P1 process at ca. 0.05, 0.10, 0.15 and 0.20 mg_{Pt}/cm², and the P4 process at 0.10 mg_{Pt}/cm², under 80°C cell temperature, 68°C dew points and 150 kPa H₂/air. 3M-24 μm, 850 EW PEM. 3M standard GDLs, all 50 cm². Actual Pt loadings of the cathodes are 0.054, 0.103, 0.146 and 0.184 mg_{Pt}/cm².

at very low (0.025 A/cm²) and high (1.5 A/cm²) currents. Measurements of the absolute and specific activities at 900 mV under 150 kPa H₂/O₂ are very similar for both processes, although the P1 cathodes have slightly higher surface area than the P4 deposited materials. In conclusion, there are slight performance benefits and no penalties for the simpler, faster P1 process for depositing the NSTF alloys.

The recently revised 2015 DOE target of 0.125 g-Pt/kW (down from 0.2 g-Pt/kW for 2015) with a total of 0.125 mg/cm² of PGM per cm² of MEA will require further work and probably a new NSTF alloy

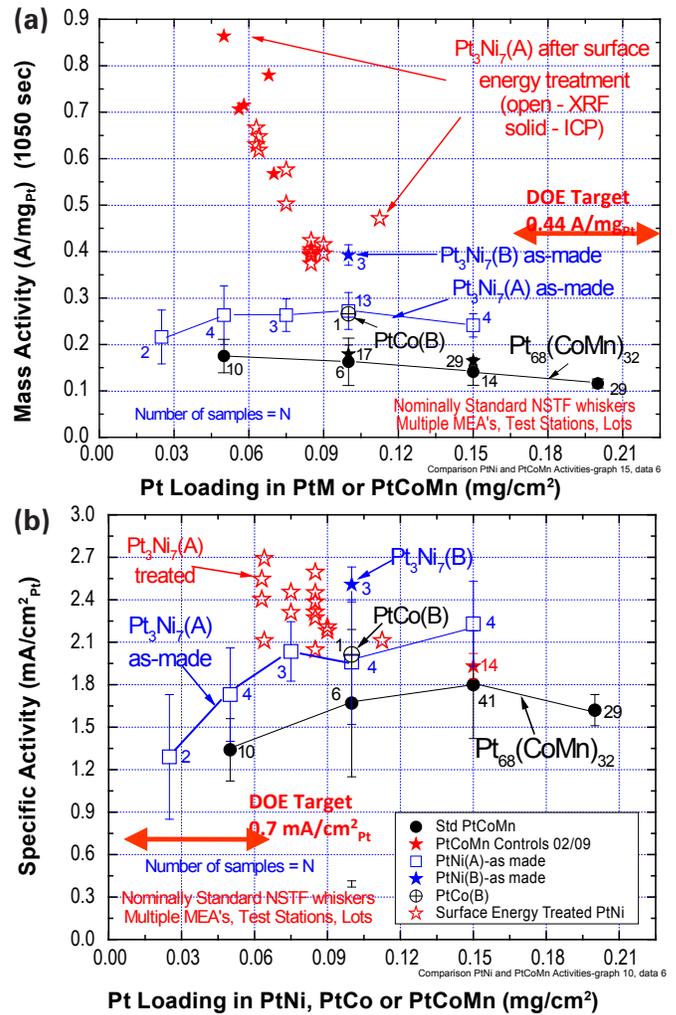

FIGURE 2. Summary of NSTF alloy ORR mass (a) and specific activity (b) as a function of Pt loading, comparing PtCoMn and Pt₃Ni₇ as-made and after surface energy treatment. Pt₃Ni₇ (A) was roll-good production fabricated at 3M. Pt₃Ni₇ (B) was lab coated at Dalhousie University with extremely thin alternating layers compared to (A).

material. This will likely be based on a Pt_xNi_y alloy, such as the unique NSTF- Pt₃Ni₇ introduced in last year’s annual report on this project and discussed in detail in reference (16). Figure 2 summarizes the ORR mass (a) and specific activities (b) measured in 50 cm² MEAs for both the PtCoMn and as-made PtNi systems. The open squares show the improvement of the as-made Pt₃Ni₇ alloy over the Pt₆₈Co₂₉Mn₃ alloy. Much higher activities are possible, however, by post-processing the as-made Pt₃Ni₇ using another process improvement we have been implementing. This process we refer to as a SET process that effectively anneals the as-made NSTF catalyst layers prior to their incorporation into a CCM. This past year it was further scaled up to allow roll-to-roll treatment.

The SET process improves the activities of both the PtCoMn and the PtNi systems, but the latter benefits much

more. SET treated production fabricated Pt₃Ni₇ (type A) cathodes are shown by the stars in Figure 2 and show there is a dramatic improvement of the measured activities over the open squares. The examples in Figure 2 were batch processed and it was necessary to re-measure the loading of the catalysts after the SET treatment in order to get accurate mass activities, as there was some loss of catalyst from the 0.1 mg/cm² as-made loadings. This measurement was done by both X-ray fluorescence (XRF) and inductively coupled plasma (ICP) as indicated by the solid and open stars in Figure 2. These values now indicate the promise for significantly exceeding the nominal 2015 DOE electrocatalyst target for mass activity at 900 mV of 0.44 A/mg. To further validate the SET treated Pt₃Ni₇ activities, a multi-sample set of 50 cm² MEAs were produced and measured at both 3M and GM using slightly different ORR activity protocols inherent to each lab. The mass loadings were also measured independently by both labs. Table 2 summarizes the results which range from 0.35 to 0.59 A/mg depending on the protocols used and confirm that the activity values are very near the DOE targets.

TABLE 2. Mass activities of surface energy treated Pt₃Ni₇ NSTF alloys measured at 3M and GM using independently measured loadings and ORR activity protocols. 50 cm² MEAs. Lab refers to the place of measurement. ORR protocol refers to the source of the protocol.

Loading Measurement Method	Lab/ORR Protocol	Mass Activity (A/mg-Pt) at 900 mV
3M XRF/ICP	3M/3M	0.59 ± 0.08
3M XRF/ICP	GM/3M	0.51 ± 0.06
3M XRF/ICP	GM/GM	0.43 ± 0.06
GM ICP	GM/3M	0.42 ± 0.08
GM ICP	GM/GM	0.35 ± 0.06

Fuel cell performance under H₂/air in the kinetic region with the Pt₃Ni₇ alloy mirrors the gain in mass activity. However a major issue with the current constructs is that the dealloying of the excess Ni into the membrane severely attenuates the high current density performance above about 0.8 A/cm², as shown in reference [14]. Proper ex situ dealloying methods are being investigated but ultimately, the structure and composition of the catalyst surface as it actually ends up in the working electrode is what we must make initially to mitigate any complex processing requirements.

Task 2

Any new electrocatalyst alloy must have the requisite durability and stability, so we continuously test our new MEA component compositions and process improvements against the DOE recommended accelerated stress tests. Below are summarized the results of three DOE defined accelerated stress tests (AST) for support, catalyst and MEA durability.

1.2 V Hold: In this test the MEA cathodes are held at 1.2 V vs. the reference hydrogen electrode (RHE) for nominally 400 hours under 150 kPa H₂/N₂ at 80°C. It effectively measures the stability of the catalyst support particle against corrosion. The DOE targets are that ORR activity and surface area will each drop ≤40%, and the performance at 1.5 A/cm² will drop less than 30 mV from initial levels. Figure 3(a) shows the series of polarization curves (DOE conditions) measured periodically over a total of 435 hours at 1.2 V, for an MEA having the P1 processed PtCoMn on the anode (0.05 mg/cm²) and cathode (0.15 mg/cm²). The MEA used a 3M made 3M-supported membrane with a chemical additive. It is apparent that the test had only a small effect on performance. Surface area loss was 10%, specific activity was unchanged, and the

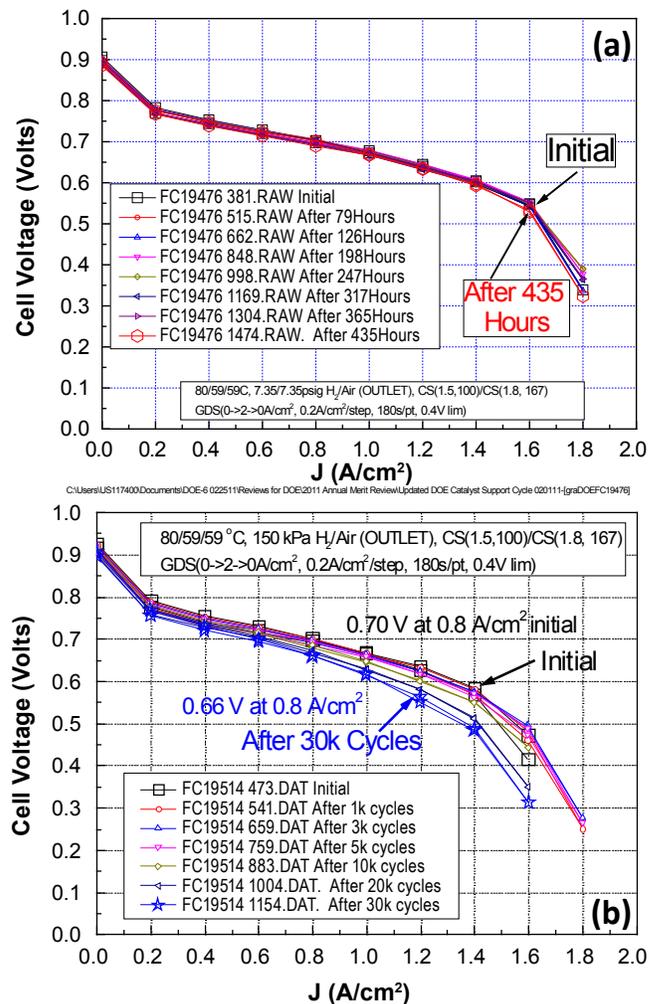

FIGURE 3. (a) Polarization curves versus time during the DOE 1.2 V hold durability test protocol. (b) Polarization curves versus time during the DOE CV cycling durability test protocol, 0.6 - 1.0 - 0.6 V, 50 mV/sec under 100/100 kPa H₂/N₂. Anode /cathode catalysts were all PtCoMn made by the P1 process at 0.05/0.15 mg_{Pt}/cm² loadings; 3M-supported PEM with additive; standard 3M GDLS.

performance at 1.5 A/cm² dropped only 10 mV, so all targets were met and repeated with a second MEA.

OCV Hold: The objective of this test is assessment of the whole MEA/membrane durability at OCV at 90°C under 30% RH, 250/200 kPa H₂/air. The target is 500 hours with less than 20% loss of OCV. Using similar or the same MEA construction as in the 1.2 V hold test, six MEAs met the 500 hour limit and cross-over targets before stopping the tests. Two MEAs were allowed to go further and have exceeded 1400 hours with ~12% loss of OCV and acceptable H₂ cross-over.

CV Cycling: This AST characterizes the resistance of the catalyst to dissolution, agglomeration or loss of activity due to high voltage cycling. The protocol involves cycling the cathode between 0.6 and 1.0 volts and back again at 50 mV/sec under 100/100 kPa H₂/N₂ at 80°C cell and dew points. The target is to have after 30,000 cycles, less than 40% loss of surface area and ORR activity and a polarization curve loss of less than 30 mV at 0.8 A/cm². This test was applied to the same MEA type as used for the previous two ASTs. The surface area loss of 18% met and exceeded the DOE target. The mass activity loss was 48% and therefore did not meet the target of ≤40%. Figure 3(b) shows the polarization curves before and after 30,000 cycles. The loss of cell voltage at 0.8 A/cm² was 40 mV, and therefore also did not meet the ≤30 mV loss target. Further results are given in reference [14], but improvements in stability under this test are required.

Task 5

Task 5 embodies all work done under catalyst/membrane integration and scale up, GDL integration and water management, and MEA component down-selection for final stack testing.

Water Management: MEAs utilizing the ultra-thin (<1 μm) 3M NSTFC technology have several demonstrated advantages compared to MEAs comprising conventional, relatively thick (~10 μm) carbon-supported catalyst, as noted in the introduction. However, the low temperature (0-50°C) steady state limiting current density of typical NSTFC MEAs with standard GDLs under usual operating conditions is substantially lower than that of many conventional catalyst MEAs (0.3 v. 1.6 A/cm² at 30°C, air cathode). This reduced low temperature performance can be attributed to the NSTFC's much higher water generation rate per unit catalyst volume and to a hydrophilic electrode pore structure that is more susceptible to water condensation. Recent studies have been conducted to better understand water management differences between NSTF and Pt/C electrode MEAs. In one study, the product water effluent rate out the cathode was evaluated at several conditions where NSTF MEAs typically show reduced performance due to flooding. By calculating the fraction of water exiting the cathode in the liquid phase and plotting against the performance loss from 80°C reference performance, reasonably quantitative

agreement is observed for both NSTF and Pt/C electrode MEAs. A primary conclusion from this study is that liquid phase product water removal out the cathode is detrimental to performance for both electrode types, but, at a given set of conditions, the total water effluent rate out the cathode is less for Pt/C electrodes than NSTF electrodes. It also stresses that taking water out the anode rather than the cathode is a most desirable strategy if possible.

In light of these results, a logical path forward was based upon the premise of minimizing liquid product water removal out the cathode GDL, which is accomplished by maximizing liquid product water removal out the anode GDL. One such method found to be effective towards this premise is decreasing the total anode pressure to enable both enhanced liquid and vapor phase product water removal out the anode GDL. This concept was introduced in last year's annual report. Decreasing the anode pressure from 200 to 25 kPa resulted in nearly a three-fold gain in the current density at 30°C cell temperature, while the limiting current density increased from 0.4 to over 2 A/cm² as the anode pressure was reduced from 150 to 50 kPa at 30°C.

A less system dependent and probably more practical method for improving the low temperature performance of NSTF MEAs is through materials development. This year we have focused on screening the anode GDL backing and microporous layer (MPL) properties. Several different vendor supplied anode GDL backings were evaluated to determine their impact on low temperature response. Figure 4(a) shows results from four tests where the anode GDL backing was varied; all GDLs contained similar hydrophobic treatments and MPLs applied by 3M. Under Test I, the MEAs with GDLs MRC A and Freudenberg A yielded similar performance whereas the MEA with MRC C had lower performance at high current density, due to higher high-frequency resistance (HFR). Under Test II, a pseudo-system startup transient, Freudenberg A GDL provided a short burst of higher performance than MRC A, but the current density dropped to the MRC A level within ~15 s. MRC C, which had lower performance than the other GDLs under Test I, yielded transient current densities which were 50% higher than Freud A and a steady-state current density approximately 3x that of the other two GDLs. Under Test III, MEAs with either MRC A or Freudenberg A GDL had similarly low performances at 30°C. As the cell was heated, the performance with both GDLs improved, with Freudenberg A having better performance at 40°C than MRC A. MRC C, which performed well under Test II, also performed well at low temperatures under Test III. As the cell temperature exceeded 50°C, all three MEAs performed similarly. Under Test IV, MEAs with either Freudenberg A or MRC C performed similarly as the current density was stepped up from 0.02 to 1 A/cm² when the cell temperature was 70°C, but at 60°C, Freud A was unable to provide a positive cell voltage at 1 A/cm² whereas MRC C only showed a slight loss relative to 70°C. These results show anode GDL properties are the most promising and effective component variable we have identified for solving low temperature

cathode flooding with ultra-thin electrodes. Exactly which properties of the GDL are most critical for this function are still unclear and something we are trying to determine.

We have also explored gradient cathode electrode options that can also provide some benefit, using hybrid combinations of NSTF and thin Pt/C dispersed layers as discussed in last year’s annual report. The ratio of benefits to added Pt loading and processing costs are not nearly as favorable as with just anode GDL optimization, and the benefit of selecting the correct anode GDL properties appears larger. This is illustrated in Figure 4(b) which is a larger summary of several GDL responses to the pseudo-system startup transient Test II discussed above, including anode GDLs comprising the MRC C (GDL C in 4(b)) with and without MPLs, the Freudenberg A type and 3M standard GDLs. Also shown in Figure 4(b) is the impact of the gradient or hybrid CCB used on the cathode with either a standard GDL on the anode or Freudenberg A or MRC C on the anode. The top three responses curves in 4(b) are obtained with the MRC C on the anode with or without an MPL and a standard cathode GDL. This combination would seem to be the best solution to the low temperature performance issue with ultra-thin electrodes, but there is still a high temperature issue with the MRC C type due to the HFR that remains to be solved as noted in Figure 4(a) test I.

MEA component down-selection: A primary focus of this project for most of the year has been the screening process for down-selecting the final MEA component sets for the final stack testing. Much of the GDL development work, P1 vs P4 catalyst deposition and SET process work discussed above were all directed at this objective. The MEA component sets investigated in this process included these bulleted items:

- Cathode catalyst: composition, loading, deposition process, post process
- Anode catalyst: composition and deposition process (finalized)
- PEM: thickness, supported vs un-supported, chemical additive levels, etc.
- Anode GDL: Backing layer type, MPL properties
- Cathode GDL: Backing layer type and MPL properties, interfacial coatings

The down-selection process itself involved evaluation of hundreds of MEAs in duplicate covering two dozen or more specific component/process parameter experiments. The results are too extensive to discuss here but more information and some examples can be found in reference [14]. The end result is that for the first short stack test we defined six MEA component configurations with three different membrane options, and three cathode catalyst options. Different GDLs were used for the anodes and cathodes, but only one type of each. The anode catalyst was fixed at NSTF-0.05 mgPt/cm² of the P1 processed PtCoMn. These six MEA types were fabricated as roll-goods and used to

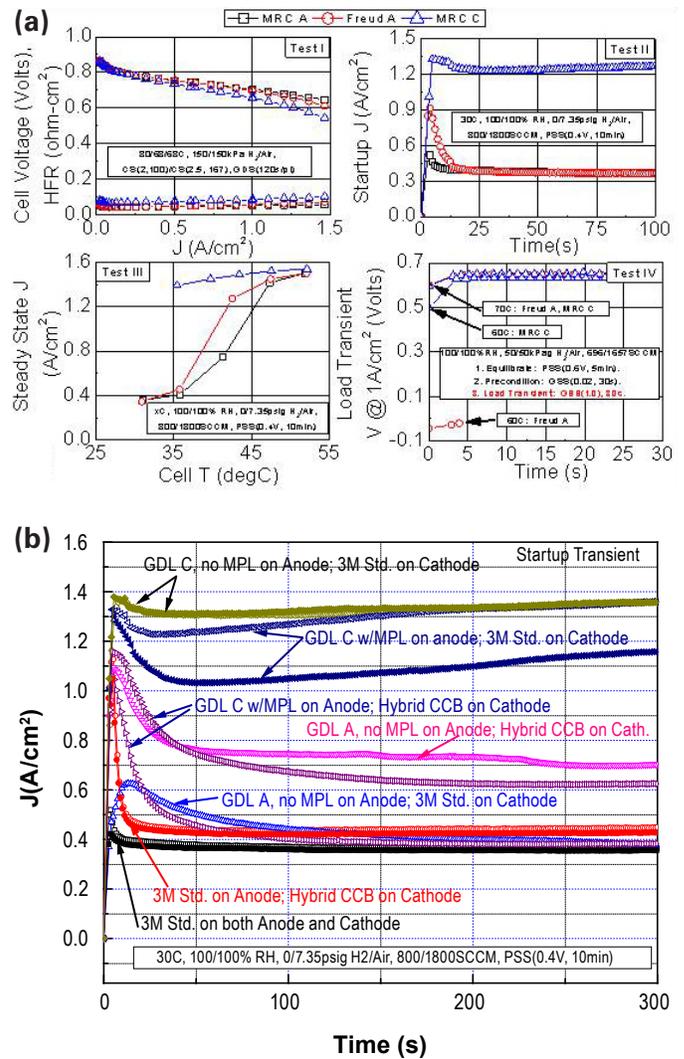

FIGURE 4. (a) Comparison of the 50 cm² cell response to four different test protocols sensitive to water management: Test I is steady-state high temperature performance; Test II is a pseudo-system startup transient at 30°C; Test III is steady-state current density at 0.4 V versus temperature; Test IV is a load transient current density step up from 0.02 to 1 A/cm² at 60 or 70°C. (b) Comparison of the 50 cm² cell response to a start-up transient (OCV to 0.4 V) at 30°C and 100% RH for different anode and cathode GDL combinations. H₂/air pressures are 100/150 kPa. GDL type C performance with or without an MPL is far superior in transient and steady-state operation to the 3M standard GDL.

populate a 29 cell “Rainbow” stack (i.e., term used by stack manufacturers to refer to different MEA configurations used in the stack metaphorically similar to the different colors seen in a rainbow), one “color” for each MEA type, for initial beginning of life operation under various automotive relevant test protocols for beginning of life testing to enable further down-selection for a second stack that will be used for longer durability studies. At the time of this report preparation the first stack is still under test.

Conclusions and Future Directions

Last year we were able to claim that this project had met or exceeded the then currently specified DOE electrocatalyst and MEA performance and durability targets for 2015 using the same MEA component set in 50 cm² cell tests. Recent tightening of the DOE 2015 targets for performance (gPt/kW) and durability has reintroduced new challenges that we must demonstrate. Significant improvements in ORR activity with NSTF-PtNi alloys and improved processing methods were demonstrated and further improvements should be possible but may not be reached by the end of this project. Continued advances this past year were made in understanding and improving low temperature water management behavior associated with the ultra-thin NSTF electrodes, particularly by identifying the importance of the anode GDL backing properties. Significant effort focused on screening and down-selecting all MEA component materials and process options for integration into an advanced robust, durable, high performance, roll-good manufactured MEA containing no more than 0.2 mg/cm² of PGM total for the final stack testing-deliverable. At this time, the stack testing has been initiated in a rainbow short stack, and performance criteria are being evaluated and compared to past short stacks and single cell results for six different MEA configurations. Specific future work will include:

- Selecting the final one or two MEA configurations for long-term testing in a second stack.
- Fabricating final MEAs sufficient for final stack(s).
- Delivering MEA media for stack integration and executing the testing plan.
- Continuing effort on one or two key issues related to anode GDLs for water management and understanding long term irreversible voltage decay.
- Exploring ex situ dealloying optimization of Pt₃Ni₇ system to achieve high current density (A/cm²).

Project End Date: October 31, 2011

Fiscal Year (FY) 2011 Objectives

- Develop structurally and compositionally advanced supported alloy catalyst system with loading ≤ 0.3 mg platinum group metal (PGM)/cm².
- Optimize catalyst performance and decay parameters through quantitative models.
- Demonstrate 5,000 cyclic hours below 80°C with less than 40% loss of electrochemical surface area and catalyst mass activity.

Technical Barriers

This project addresses the following technical barriers from the Fuel Cells section (section 3.4.4) of the Fuel Cell Technologies Program Multi-Year Research, Development and Demonstration Plan:

- (A) Durability
- (B) Cost
- (C) Performance

Technical Targets

TABLE 1. DOE 2011 Technical Targets for Electrocatalysts and the Current Status of this Project

Electrocatalyst Targets	Units	Current Status	DOE 2010 Target	DOE 2015 Target
PGM (total content)	g/kW	0.50	0.3	0.2
PGM (total loading)	mg/cm ²	0.40 ^a	0.3	0.2
Mass Activity @ 900 mV	A/mg _{PGM} at 900 mV (iR-free)	0.20 (in MEA) 0.30 (in liquid cell)	0.44	0.44
Specific Activity	μA/cm ² at 900 mV (iR-free)	940 (in MEA) 612 (in liquid cell)	720	720
Cyclic Durability At T ≤ 80°C	h	1,450 ^{b,c}	5,000	5,000
At T > 80°C	h		2,000	5,000
Electrochemical Area (ECA) Loss	%, percent	30 ^d	<40	<40
Cost	\$/kW at \$51.55/g	~26 ^e	5	3
Electrocatalyst Support mV after 400 hours @ 1.2 V	mV	92 ^f	<30	<30

^a Based on current scaled-up 30% Pt₂IrCr/C membrane electrode assembly (MEA); anode/cathode loading – 0.1/0.3 mg/cm² (PGM).

^b Under an accelerated vehicle drive cycle protocol in a short stack; 40% mass activity loss under UTCP-defined accelerated single-cell test after 270 hours at 70°C and 120 hours at 80°C.

^c Short stack durability test is on-going.

^d Durability data measured after 30,000 cycles under UTC-defined accelerated test protocol.

^e Five-year average PGM price \$51.55/g (Pt = \$1,234.33/Troy Oz; Ir = \$369.06/troy oz); costs not projected to high volume production.

^f 40 mV internal resistance (iR)-free O₂ performance loss at 1.5 A/cm² after 360 hours at 1.2 V.

T - temperature

FY 2011 Accomplishments

- Completed the scale up and MEA optimization of down-selected dispersed catalyst, 30% Pt₂IrCr/C for performance in a full-size fuel cell. A mass activity of 0.2 A/mg(PGM) was achieved compared to the previous status of 0.14 A/mg(PGM).
- Completed the durability testing of 30% Pt₂IrCr/C in a full-size MEA was completed under an accelerated protocol which showed 400 hrs of stability at 70°C. Currently testing performance and durability of the 30% Pt₂IrCr/C in a short stack.
- Durability testing of 30% Pt₂IrCr/C in a short stack is in progress under an accelerated vehicle drive cycle

protocol. The stack has accumulated 1,450 hours of uninterrupted operation at 70°C in H₂/air.

- Scaled up a 20% Pt₂IrCr alloy on the down-selected durable carbon, C4, and completed preliminary optimization of MEA for subscale fuel cell performance and stability testing in a porous plate subscale fuel cell under the DOE catalyst support corrosion protocol. A 40 mV iR-free O₂ performance loss at 1.5 A/cm₂ was observed after only 360 hours of potential holds at 1.2 V.
- A No-Go decision was made for core-shell catalysts based on extensive physical characterization and durability studies. Activity and stability of Pt_{ML}/Pd₃Co core-shell catalysts prepared using scalable chemistries were evaluated using both rotating disk electrode (RDE) and subscale fuel cell tests. Higher temperature and more concentrated electrolyte contributes to Pd dissolution and is substantially more damaging than room temperature RDE testing.

Introduction

For the proton exchange membrane fuel cell (PEMFC) technology to become commercially viable, the cost of the components in a fuel cell must be reduced and, more importantly, the durability of the MEA must be improved. This project focuses on two distinct approaches to the DOE 2010 durability and performance targets. The first approach is the development of conventional but high performance highly dispersed Pt alloy catalyst on a carbon support. The second system utilizes a novel “Pt monolayer (ML) core-shell” approach capable of achieving very high Pt mass activities [1-3]. Under this latter concept, the main objectives are to improve the durability of the cathode catalyst by further optimizing the core material selection, shell thickness of the ML, and the particle size of the cores and to develop scalable fabrication methods.

Approach

To achieve the objectives on this project, UTCP has teamed with Brookhaven National Laboratory (BNL), Texas A&M University (TAMU) and Johnson Matthey Fuel Cells (JMFC). The research focus and the role of all partners were reported previously [4]. BNL's role on the project focuses on the development of Pt ML “core-shell” systems on various cores including ideal surfaces such as single crystals. In addition, BNL leads our efforts to understand the effect of electronic properties, crystal structure and particle size on activity and durability of this class of electrocatalysts. TAMU focuses on development of computational atomistic models to study parameters that influence the activity and durability of core shell and dispersed catalyst systems. The overall scope of JMFC activities in the project encompasses

development of (i) dispersed Pt alloy catalysts including scale-up on conventional and advanced carbon supports, (ii) novel synthesis methodologies to scale up Pt ML core-shell catalysts, and (iii) MEA optimization and fabrication. Apart from overall project management, UTCP primarily focuses on the development of advanced dispersed Pt-based binary and ternary alloy catalysts. UTCP activities also include electrode modeling for MEA optimization, carbon support corrosion studies, fuel cell testing on single-cell level and fabrication and testing of a 20-cell short stack for verification.

Results

Molecular Modeling

It was previously reported that incorporating Ir into the bimetallic Pt₃M alloy increases the tendency of Pt-skin formation and enhances the stability of the alloy systems [4]. The main topic that was studied this year was calculation of activity and stability of PtIrM ternary alloys based on experimentally found structures including surface segregation trends, Bader charge and D-band center analysis of Pt. Previously, the change in the composition of the Pt, Ir and Co in a 30% Pt₇IrCo₇/C as a function of cycling and the corresponding mass activity from RDE experiments were reported. A substantial loss of Co and Ir within the first 5,000 potential cycles results in a composition equivalent to that of a Pt₃IrCo. The role of Ir and Co on the surface properties of two structures: Pt₈IrCo₃ (that resulted after acid exposure) and Pt₁₁IrCo₄ (composition obtained after 5,000 cycles) alloys were studied by density functional theory calculations.

The role of Ir and Co on the surface properties of PtIrCo alloys was studied by a comparative analysis for the Pt₈IrCo₃ and Pt₁₁IrCo₄ systems using two different 5-layer distribution structure models as shown in Figure 1. The results show that the most stable structures for Pt₈IrCo₃ are the structures with one layer of Pt skin surface followed by the two-layer Pt skin surfaces. In both cases, the Pt-skin layers are more stable than the un-segregated structure. However, differences among different structures also depend critically on the subsurface composition. For example, the most stable one-layer Pt skin surface has a second layer of Pt₃Co which is slightly more favorable than a PtCo in the second layer. Similar results were obtained for the Pt₁₁IrCo₄ system where the most favorable second layer composition is PtCo, followed by Pt₃Co, and the movement of Ir from fourth to the third layer does not affect the results. In summary, for the cycled and acid-treated structures, the single-layer Pt-skin surfaces are the most stable. However, the two-layer Pt-skin surfaces may be formed and are thermodynamically more favorable than the non-segregated structures. Co atoms tend to be in the second and third layers, and Ir atoms tend to be in the core, together with fourth and fifth layer Pt atoms that do not show a trend to segregate towards the top surface.

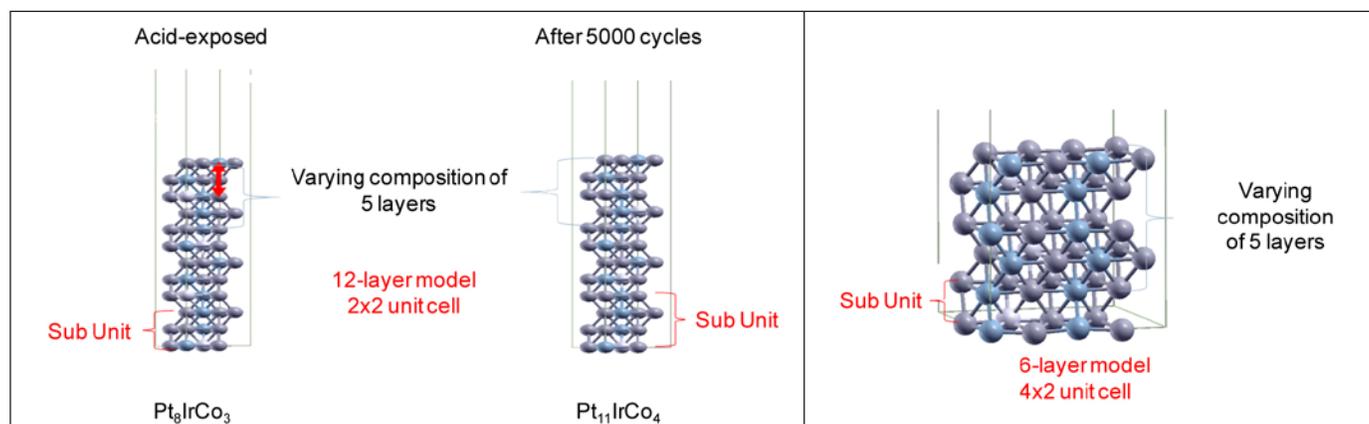

FIGURE 1. (a) 2x2 and (b) 4x2, slab model used to study segregation in Pt_8IrCo_3 and $Pt_{11}IrCo_4$ systems. The first five layers are used to study atomic redistribution after leaching. The optimized lattice constants are 3.853 Å for Pt_8IrCo_3 and 3.851 Å for $Pt_{11}IrCo_4$.

The activity and stability of the 30% Pt_7IrCo_7/C after potential cycling were studied and Table 2 shows the electrochemical stability values for the $Pt_{11}IrCo_4$ (composition after 5,000 cycles) structure in vacuum which shows that the stability of the cycled alloy surface is higher than that of the two-layer skin from Pt_2IrCo and comparable to that of the single-layer skin of Pt_3Co surfaces as shown by their electrochemical potential relative to a Pt (111) surface.

TABLE 2. Electrochemical Stability of Pt Surface Atoms Pt Surface Atoms in Two-Layer Alloy Relative to Clean Pt (111) Surfaces

System	μ_{Pt} (eV)	$\Delta\mu$ (eV)	ΔU (V)
Pt(111)	-6.98	0	0
Pt_3Co (111) Single-layer Pt-skin	-7.22	-0.24	0.12
Pt_2IrCo (111) two-layer Pt-skin	-7.12	-0.14	0.07
$Pt_{11}IrCo_4$ (111) two-layer Pt-skin	-7.23	-0.25	0.13

The average charge (based on a Bader charge analysis) of the first four layers of the $Pt_{11}IrCo_4$ indicates a charge transfer from the Co subsurface atoms to the Pt atoms in the second layer and to the Ir atoms in the third layer and that the charge of the surface Pt atoms remains very similar to that on the pure Pt (111) surface suggesting an increased activity of the $Pt_{11}IrCo_4$ surface. Similar results are also obtained from the analysis of the density of states calculations which suggest enhanced reactivity of the surface Pt layer (d-band center shifted in the direction of the Fermi level). Weak adsorption of O and OH intermediates are also observed compared to Pt (111) surfaces which confirms the higher activity of the $Pt_{11}IrCo_4$ alloy surface. Furthermore, the electrochemical stability values for the $Pt_{11}IrCo_4$ structure with 0.25 ML of adsorbed oxygen (Table 3) shows a decrease in surface stability of the cycled alloy surface. However, the stability is still comparable to those on pure

Pt (111) surfaces. These findings support the activity and stability of the 30% Pt_7IrCo_7/C observed experimentally [5].

TABLE 3. Electrochemical Stability of Pt Surface Layer Under 0.25 ML of Adsorbed O in Two-Layer Alloy Surface shown in Table 1 Relative to Pure Pt(111) Surfaces

System	μ_{Pt} (eV)	$\Delta\mu$ (eV)	ΔU (V)
Pt(111)	-6.26	0	0
Pt_3Co (111) Single-layer Pt-skin	-6.55	-0.29	0.15
Pt_2IrCo (111) two-layer Pt-skin	-6.32	-0.06	0.03
$Pt_{11}IrCo_4$ (111) two-layer Pt-skin	-6.14	0.12	-0.06

Dispersed Pt Alloy Catalyst

Many factors such as structure, particle dispersion, particle size, type of carbon support etc, influence the electro-catalytic activity of Pt and Pt alloy nanoparticles. Previously, within this project, a 30 wt% Pt_2IrCr cathode ($0.3 \text{ mg}_{PGM}/\text{cm}^2$ loading) showed higher durability in both ECA and mass activity (MA) under potential cycling. This catalyst showed much lower loss (~30% ECA and MA) compared to the standard Gore Pt/C ($0.4 \text{ mg}_{PGM}/\text{cm}^2$ loading) which showed ~50% loss and was down-selected for further development and scale up into full-size MEAs [4]. In the past year, a significant amount of effort was focused towards development and optimization of the cathode catalyst layer in an MEA with 30% Pt_2IrCr alloy catalyst to improve the catalyst utilization in electrodes keeping low PGM loading and enabling good performance at high current densities. This involved an elaborate investigation to identify key parameters such as catalyst ink formulations and ionomer content, to produce an optimum cathode catalyst layer capable of achieving good fuel cell performance in wide range of current densities.

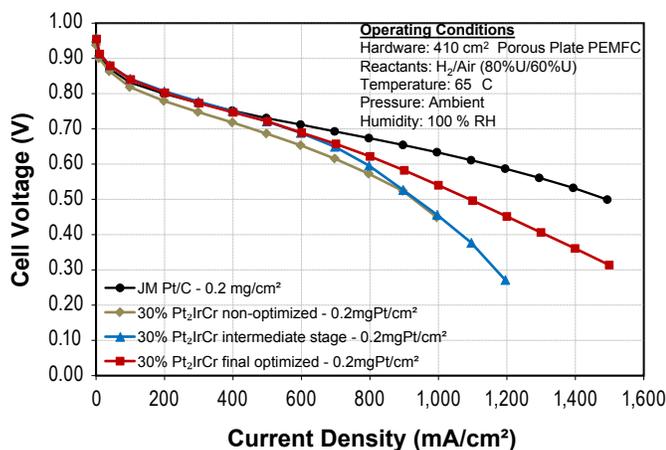

FIGURE 2. Fuel cell polarization curves in H₂/air at 65°C in a water transport plate (WTP) fuel cell at 100% relative humidity (RH) and ambient pressure for an optimized, intermediate stage and un-optimized 30% Pt₂IrCr/C ternary alloy catalyst MEA compared to JMFC Pt/C (0.2mg_{Pt}/cm²) MEA.

Figure 2 shows the fuel cell performance curves in H₂/air at different stages of the optimization process for the 30% Pt₂IrCr/C MEA in a full size (410 cm²) WTP fuel cell compared to a baseline JMFC Pt/C MEA. The initial mass activity obtained for the alloy catalyst in the optimized MEA were 0.14 A/mg_{PGM} compared to a MA of 0.19 A/mg PGM observed for the JMFC Pt/C MEA. This low activity is attributed to the low utilization of the catalyst in the MEA as seen by the low ECA of ~30 m²/g (vs. liquid cell ECA of 45 m²/g from RDE). However, a clear evidence of improvement for high current density performance on H₂/air in a WTP fuel cell is observed from these catalyst layer optimization steps. Our results show that lower catalyst loading of 0.3 mg_{PGM}/cm² in the MEA can achieve high initial performances, although lower than the pure Pt/C. Extensive investigation into MEA fabrication process suggests that specific ink formulations significantly increase either mass transport properties or kinetic performance of alloy catalysts. This increase is attributed to the concentration of the ionomer in the ink formulations which results in the leaching of the Cr atoms from the catalyst surface to different concentrations and concurrently affects the kinetic and high current density performance in an MEA.

Figure 3 shows the (a) MA loss and (b) cell voltage at 0.8A/cm² on H₂/air for the 30% Pt₂IrCr/C and the JMFC Pt/C in a WTP fuel cell under two durability protocols. A higher rate of MA and performance loss is observed for the Pt-alloy compared to the pure Pt at both operating temperatures. This higher rate is attributed to the lower stability of the transition metal in the Pt-alloy which results in the higher rate of MA loss. Additionally, any Cr leaching into the MEA would result in higher iR losses as observed by the cell voltage drop in the high current density region during cycling. Higher MA and cell voltage loss are

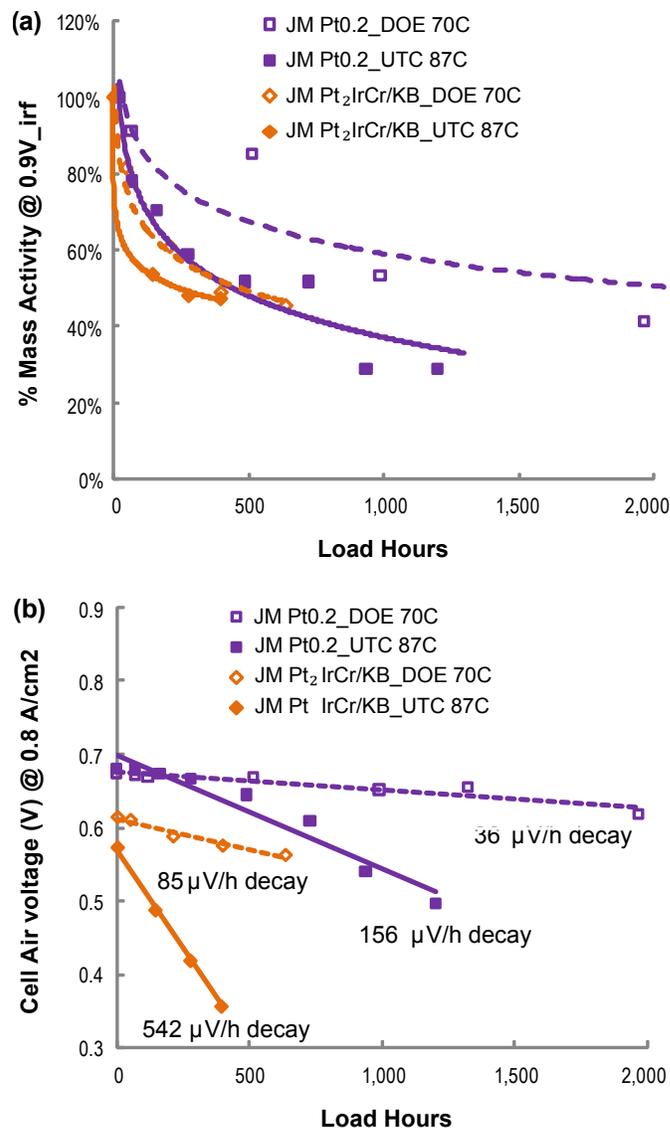

FIGURE 3. (a) Percentage mass activity and (b) cell air voltage at 0.8 A/cm² for the optimized 30% Pt₂IrCr/C MEA and JMFC Pt (0.2 mg_{Pt}/cm²) MEA in a full-size WTP cell under two durability protocols at 70°C and 87°C, respectively.

observed with increase in operating temperature of the fuel cell for both Pt and Pt-alloy. This observation suggests that the rate of degradation of the catalyst is highly dependent on the operating temperature of the fuel cell and the cycling protocol. Due to insufficient data available in the literature on the durability of alloy catalysts under real life conditions, a short stack containing the Pt-alloy was built and its durability under an accelerated vehicle drive cycle protocol will be evaluated.

Durable Carbon Support

The main focus of this task was to explore alternate durable carbon supports capable of withstanding high

voltage spikes relevant for automotive applications. In the past year, a scaled-up batch (200 g) of 20% Pt₂IrCr on the down-selected stable carbon (C4) was prepared by JMFC and optimized for performance in sub-scale size (25 cm²) WTP cells. The effect of cathode catalyst layer compositions including ionomer equivalent weight and ratio of ionomer to carbon were extensively investigated using subscale fuel cell testing. Figure 4a shows performance curves for a preliminary optimized MEA compared to a commercial Gore 57 Pt/C in subscale size WTP fuel cells operating at 80°C, 100% RH, 0 kPa backpressure. The Pt-alloy/C4 performance at high current operations is still poor mainly due to the low surface area and poor mass transport

properties of the carbon support C4. Figure 4b shows the iR-free cell voltages at various current densities (0.1, 1 and 1.5 A/cm²) for a 0.2 mgPt/cm² 30% Pt/C4 and 20% Pt₂IrCr/C4 compared to a 30% Pt/C MEA obtained from a 25 cm² WTP fuel cell testing at 80°C, 100% RH under H₂/O₂ at zero backpressure. Although the beginning of life performance for the Pt and Pt-alloy supported on C4 low surface area carbon shows lower performance than that of the Pt/C, its performance after the 1.2 V potential hold tests show considerable differences. After the fuel cell corrosion test of a total of 17 potential holds of 24 h each (408 h total) at 1.2 V, the 30% Pt/C4 and 20% Pt₂IrCr/C4 showed 59 mV and 92 mV loss, respectively, at 1.5 A/cm² under H₂/O₂. While the alloy on C4 did not meet the 2010 DOE target of less than 30 mV iR-free O₂ performance loss at 1.5 A/cm² after 400 h, the voltage loss after 360 h (15 potential holds of 24 h each) at 1.2 V for the alloy catalyst was only 40 mV. The durability of the 20%Pt₂IrCr/C4 under the accelerated potential cycling protocol is currently under investigation.

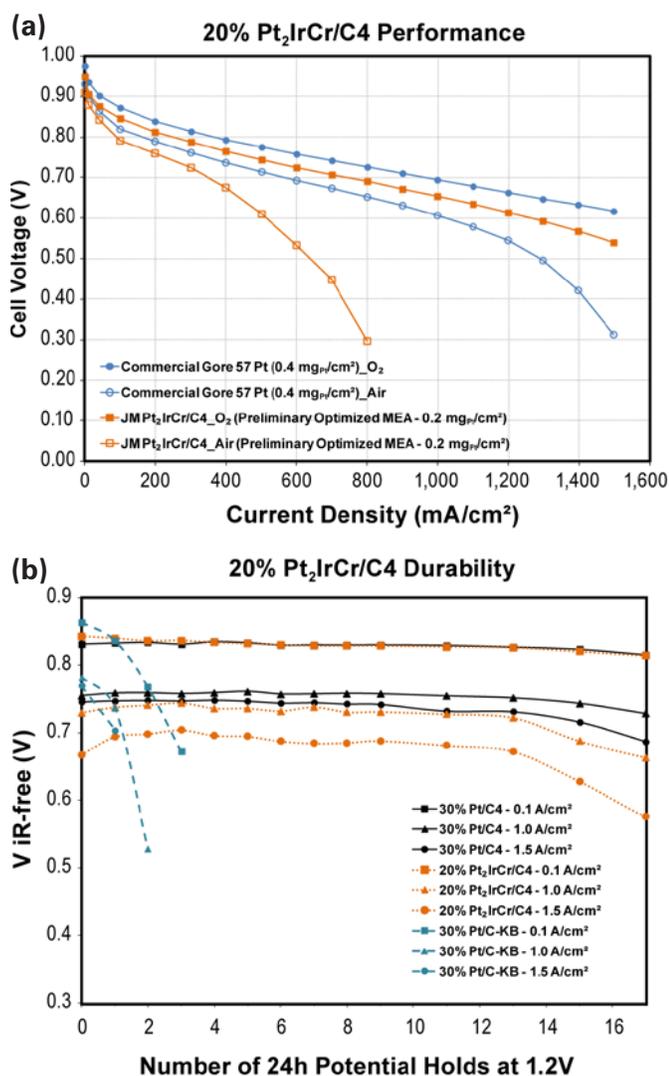

FIGURE 4. (a) Fuel cell performance curves at beginning of life for a 20% Pt₂IrCr/C4 compared to a standard 0.4 mg_{Pt}/cm² Gore 57 Pt/C MEA obtained from WTP subscale fuel cell (25 cm²) testing at 80°C, 100% RH under H₂/air at zero backpressure and (b) H₂/O₂ performance at 0.1, 1 and 1.5 A/cm² after 1.2 V potential holds in H₂/N₂ at 80°C, 100% RH in subscale WTP cells for (0.2 mg_{Pt}/cm² loading) 30% Pt/C4 and 20% Pt₂IrCr/C4 compared to a 30% Pt/C MEA.

Conclusions and Future Directions

The effects of MEA compositions were studied for the scaled-up 30% Pt₂IrCr/C in full-size WTP fuel cells. A short stack containing the Pt-alloy was built and its durability under an accelerated vehicle drive cycle protocol is currently under investigation. Key barriers to overcome for the incorporation of the 30% Pt₂IrCr in an MEA such as low catalyst utilization in electrodes and the transition metal stability under operating conditions still remain open. A No-Go decision was made for core-shell catalysts due to their poor durability in an MEA under operating fuel cell conditions. The scaled up synthesis of a 20% Pt₂IrCr/C4, the down-selected catalyst on stable carbon, preliminary MEA optimization and corrosion durability testing is complete. However, their performance at high current operations is still poor and is being further investigated.

Future Directions

Our future objective is to demonstrate (i) the durability of the 30% Pt₂IrCr/C in a short stack and (ii) the high current density performance of the 20% Pt₂IrCr/C4 alloy catalyst in a subscale and full-size WTP fuel cell at the conditions relevant for automotive applications. Some of the tasks undertaken to achieve these goals are listed below.

- Continued operation of the 30% Pt₂IrCr/C in a 20-cell short stack under an accelerated vehicle drive cycle protocol.
- Optimization of dispersed alloy catalyst systems on C4 in MEAs is in progress, aiming to approach high current density performance in an operating fuel cell. The higher mass transport losses and poor water management issues are being resolved by tailoring the electrode structure for performance in a WTP fuel cell.
- In the case of the core-shell catalysts, preventing dissolution of the core material from the bulk phase of

nanoparticles remains a major challenge for this class of catalysts, and hence all activities under this task have been terminated and will not be investigated for the rest of the project.

Project Start Date: August 1, 2009

Projected End Date: July 31, 2013

Fiscal Year (FY) 2011 Objectives

- Develop catalysts that will enable proton exchange membrane (PEM) fuel cell systems to weather the damaging conditions in the fuel cell at voltages beyond

the thermodynamic stability of water during the transient periods of start-up/shut-down (SU/SD) and fuel starvation.

- Demonstrate that these catalysts will not substantially interfere with the performance of, nor add much, to the cost of the existing catalysts.

Technical Barriers

This project addresses the following technical barriers from the Fuel Cells section of the Fuel Cell Technologies Program Multi-Year Research, Development and Demonstration Plan:

- (A) Durability
- (G) Start-up and Shut-down Time and Energy/Transient Operation

Technical Targets

While the number of SU/SD cycles for an automotive fuel cell has been estimated to be over 30,000, the number of these events when the cathode electrochemical potential exceeds 1.23 V has been estimated at ~5,000. The number of complete fuel starvation events when a cell experiences a voltage reversal has been estimated at ~200 [1].

In agreement with DOE, the technical targets for the second year of the project have been defined as follows:

- For SU/SD, develop a cathode catalyst that can survive 5,000 excursions (<5 s each) to potentials <1.45 V, with current densities >1 mA/cm². Oxygen evolution reaction (OER) catalyst loading to be kept <2 µg/cm² of platinum group metals (PGMs)
- For cell reversal, develop anode catalyst that can withstand 200 pulses of -200 mA/cm² while maintaining cell voltage <2 V.

FY 2011 Accomplishments

- Both of the technical targets for the second year have been met.
- Generic electrochemical tests for SU/SD and cell reversal were developed and implemented.
- 10,000 SU/SD cycles were achieved with addition of only 2 µg/cm² PGM.
- 200 high current densities pulses of -200 mA/cm² for cell reversal were achieved with 60 µg/cm² of total PGM with cell voltage <1.7 V.
- Platinum dissolution is satisfactorily prevented when the potential is maintained below 1.7 V.
- Advantage of OER-modified Pt/nano-structured thin-film (NSTF) over OER added Pt/C catalyst was clearly established.

- Progress in elucidating the roles of Pt and the added OER catalysts was made.
- Fully characterized coatings with X-ray photoelectron spectroscopy (electron spectroscopy for chemical analysis) show indications of interaction of the OER catalysts with the substrate, potentially favorable from a durability point of view.
- High resolution transmission electron microscopy depicting the nanoparticles of Ir and Ru on NSTF provided insight into the observed fuel cell performance and oxygen reduction reaction (ORR) activity.
- Chemically modified Pt/NSTF anode exhibited very low ORR without inhibiting hydrogen oxidation reaction (HOR).
- Independent original equipment manufacturer testing confirmed the 3M lab results.
- OER catalyst scale-up: large size catalyst-coated membranes were fabricated at the 3M pilot plant.

Introduction

The project addresses a key issue of importance for successful transition of PEM fuel cell technology from the development to pre-commercial phase (2010 - 2015). This issue is the failure of the catalyst and the other thermodynamically unstable membrane electrode assembly (MEA) components during SU/SD and local fuel starvation at the anode, commonly referred to as transient conditions. During these periods, the electrodes can reach potentials up to 1.8 V. One way to minimize the damage from such transient events is to lower the potential seen by the electrodes. At lower positive potentials, increased stability of the catalysts themselves and reduced degradation of the other MEA components is expected.

Approach

This project will try to alleviate the damaging effects during transient conditions from within the fuel cells via improvements to the existing catalyst materials. We are modifying both the anode and the cathode catalysts to favor the oxidation of water over carbon corrosion by maintaining the cathode potential close to the thermodynamic potential for water oxidation. The presence of a highly active OER catalyst on the cathode reduces the overpotential for a given current demand thus reducing the driving force for carbon and platinum dissolution. In addition, inhibition of the ORR on the anode side lowers the ORR current through reduced proton demand which in turn decreases the OER current on the cathode resulting in reduced cathode potential.

Key requirements for both concepts are to implement the added catalyst with negligible inhibition of the fuel cell performance and with minimal increment of PGM.

Results

Task 1. Efficient Oxygen Evolution Reaction Catalysts

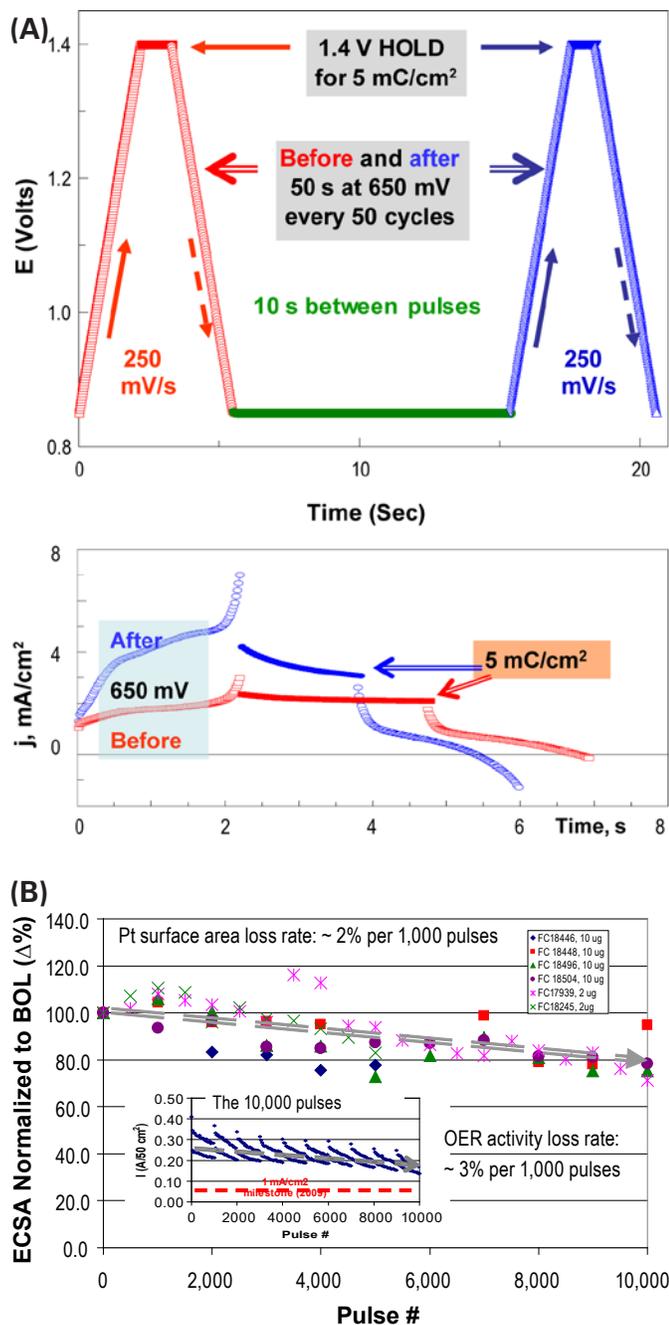

The activity during the second year of the project related to this task and revolved around the model catalyst containing ruthenium and iridium [2]. We have shown that the oxides of ruthenium, known to have the best catalytic properties for OER in aqueous solutions, and iridium, known to be the more stable of the two, exhibit the same properties as tested in an MEA [2,3]. To get the advantage of both Ru and Ir, the OER catalysts tested during this reporting period were nominally 90% Ir and 10% Ru. This composition seemed to exhibit the best stability and to provide enhanced OER activity relative to Ir only. All the catalysts were tested in a 50-cm² PEM fuel cell, with the working electrode under nitrogen and the reference/counter under either 1% or 100% hydrogen.

SU/SD Test

The first subtask during the second year of the project was the development of a generic, electrochemical test mimicking the real SU/SD events. The principles of the test were based on:

- The amount of air present in the anode compartment during the startup of the fuel cell stack.
- The equivalent amount of charge required for a substantial portion of the oxygen fraction in the air to be reduced.
- Requirement that the voltage does not go over 1.45 V (project milestone).
- Requirement that the OER current does not fall below 1 mA/cm² (project milestone).
- Constraint that the time for the required charge to be delivered to is <10 seconds.
- The catalyst should withstand 10,000 high voltage excursions (pulses/cycles).

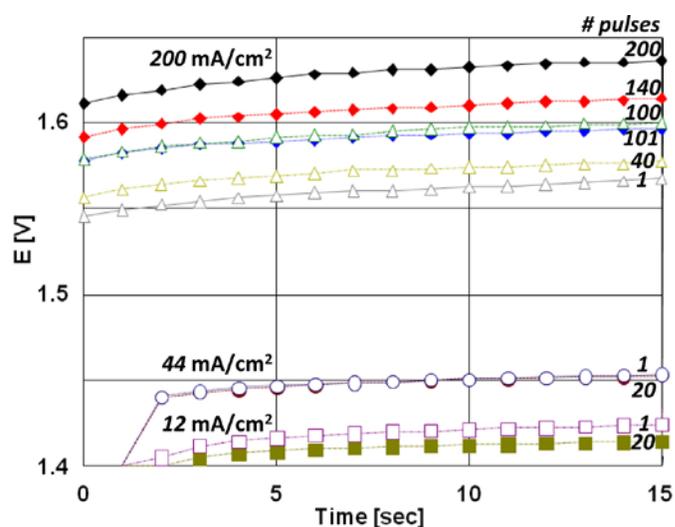

In order to further mimic the real fuel cell operating conditions, after every 50 pulses to 1.45 V, the catalyst was periodically exposed to ~0.7 V. Further, in order to mimic the incoming hydrogen front during the startup, a potential ramp of 250 mV/s from the open-circuit voltage, 0.9 V, was imposed. Schematic presentation of the test protocol along with the actual cell response is presented in Figure 1. There is a difference in the current response depending on whether the potential ramp is imposed immediately after the cell has been exposed to 0.7 V or later on during the consecutive cycles (Figure 1A). This difference is due to the oxidation current going towards formation of the PtOx on freshly reduced catalyst. The OER, however, starts at ~1.3V regardless of the state of the platinum. The change of the Pt surface area was adopted as a metric of the successful protection of the platinum. The electrochemically active surface area (ECSA) was measured after every

BOL - beginning of life

FIGURE 1. (A) Schematic presentation of the electrochemical test protocol (upper) along with the actual cell response (lower). Steps description: 250 mV/s potential sweep up; 1.4 V HOLD to 5 mC/cm²; 250 mV/s potential sweep down; 10 s at 850 mV; 650 mV every 50 cycles/pulses; ECSA every 1,000 cycles. 50-cm² MEA under nitrogen/1% hydrogen, 70°C, fully saturated. *Note:* Current responses during the potential sweep up, mostly reversible, depend dramatically on OER catalyst state. (B) Pt ECSA changes during SU/SD test and OER catalyst activity decay (inset) during 10,000 cycles. Four 0.15 mg Pt/NSTF catalysts with 10 μg/cm² and two with 2 μg/cm² additional OER catalyst are presented.

FIGURE 2. Cell reversal test procedure and the typical outcome; cell voltage responses during first 15 seconds are presented. Note the “reverse” order of the pulse #1 and #20 for 20 mA/cm² and 44 mA/cm² due to activation of the OER catalyst and between #100 and #101 at 200 mA/cm² due to regeneration for 10 minutes at ~0.0 V.

to achieve 10,000 pulses with approximately 2% loss of ECSA/1,000 cycles. At the same time the OER catalyst itself lost 30% of its original activity (see inset in Figure 1B).

Cell Reversal Test

In electrochemical terms, the cell reversal requirements are equivalent to testing the OER activity at high current densities. In Figure 2 the test procedure and the typical outcome is presented. Essentially, the test protocol is based on the fact that during cell reversal the anode is exposed to very positive voltages, 2 V and higher. Usually, such highly damaging conditions do not last for a very long period of time. Consequently, the core of our test consists of 200 pulses at 200 mA/cm² followed by 1 minute at potential close to 0 V [1]. As depicted in Figure 2, the potential with every consecutive 200-mA/cm² is more positive. However, the presence of a good OER catalyst does keep the

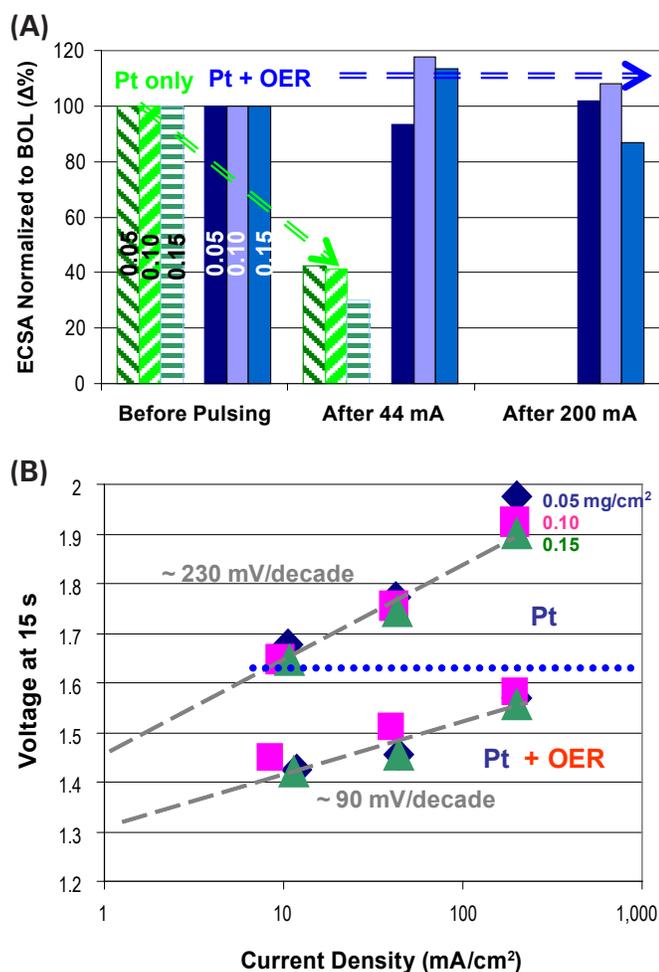

FIGURE 3. The effect of OER catalysts on platinum stability; Pt loading: 0.05, 0.10, and 0.15 mg/cm^2 ; OER catalyst loading: 10 $\mu\text{g}/\text{cm}^2$. (A) Platinum ECSA loses after 44 mA/cm^2 pulses without (solid blue) and with the OER catalyst (shaded green). (B) Cell voltage dependence on Pt loading. *Note* the Tafel like dependence for both catalysts on Pt loading.

potentials below 1.7 V. In Figure 3 the effect of the presence of the OER catalysts and the effect of the platinum loading are presented. As is clear from the figure, regardless of the loading, platinum without the OER catalyst loses over 50% of the original surface area even after the initial low current densities pulses (Figure 3A). The most obvious reason for this loss is the fact that, at 44 mA/cm^2 , the OER on Pt proceeds at potentials almost 0.3 V higher than the same Pt catalyst with addition of the Ir + Ru (Figure 3B).

In Figure 4, a comparison between the cell reversal behavior of OER-modified Pt/NSTF substrate and dispersed Pt/C with admixed IrRu catalyst is presented. In spite of the fact that the dispersed catalyst has twice as much OER catalyst, the performance and therefore the stability of NSTF-based catalyst is far superior (Figure 4A). It is worth pointing out that the Pt ECSA for Pt/C dropped 86% during the test while Pt/NSTF remained practically the same. The superior durability of the Pt/NSTF with OER catalyst was

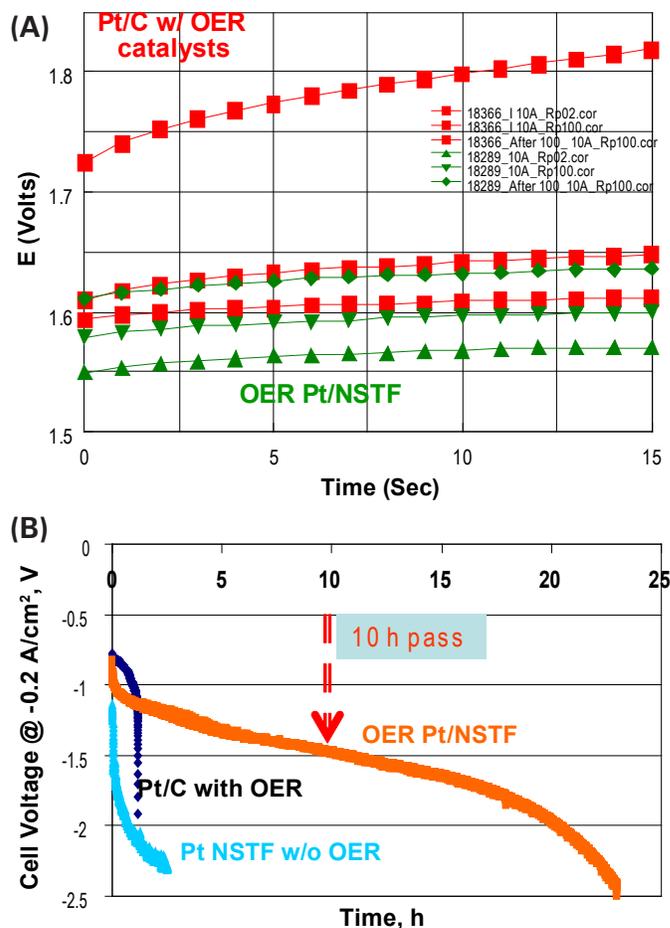

FIGURE 4. Comparison of cell reversal behavior between OER-modified Pt/NSTF substrate and dispersed Pt/C with admixed IrRu catalyst. Same Pt loading; 2X OER catalyst on Pt/C. (A) Cell voltage during 15 seconds pulses at 200 mA/cm^2 : Pulse # 2; 100; 200 presented. (B) AFCC cell reversal test under nitrogen/air: Continuous -200 mA/cm^2 .

confirmed by an independent testing completed by the stack manufacturer AFCC (Figure 4B). Moreover, the OER-modified Pt/NSTF is the only catalyst that achieved the AFCC required 10 hours “pass” point.

Task 2. Anode Catalysts with Low Oxygen Reduction Reaction Activity

The intent of this work is to find compositions that dramatically reduce the ORR activity of the deposited Pt while still maintaining high HOR activity. Numerous composition spreads were prepared via sputter deposition at Dalhousie University. These spreads included depositions from sputtering targets such as Ti, Ta, ZrO, SiO₂, polytetrafluoroethylene (PTFE), etc. over the top of Pt (“overlayer” spreads) and co-depositions from Pt and targets such as Ta, Nb, Ti, Hf, TiO₂, Ag (“intermix” spreads). However, the best success was achieved by our partners at ANL. They successfully deposited calix[4]arene molecules on 3M Pt/NSTF with properties close to ideal to the goal of this task [4].

Conclusions and Future Directions

- The main conclusion is that platinum dissolution can be satisfactorily slowed down when the OER catalyst maintain the electrode potential below 1.7 V.

Future Work

- Modify/simplify test procedure to reflect “real life”, taking into account the U.S. DRIVE Tech Team and DOE Durability Work Group inputs.
- Explore further the Ir/Ru/Pt model system space by implementing new Pt + OER catalysts architectures.
- Explore the practicality of sputter-deposited and/or chemically modified anode for low ORR (ANL).
- Understand further the protective domain and the role of the OER catalyst by relying on state-of-the-art instrumental techniques available at the National Labs (ORNL, ANL).
- Work toward reaching the project Go/No-Go targets as proposed according to new DOE performance targets for total PGM loading:
 - 200 cycles of -200 mA/cm^2 for cell reversal with 0.045 mg/cm^2 total PGM on the anode with 1.8 V upper limit.
 - 5,000 startup cycles under the existing protocol with 0.09 mg/cm^2 total PGM on the cathode with Pt ECSA loss of $<10\%$.
 - Reduce ORR current on the anode by a factor of 10.

Project Start Date: July 20, 2009

Project End Date: 2013

Technical Barriers

This project addresses the following technical barriers from the Fuel Cells section (3.4.4) of the Fuel Cell Technologies Program's Multi-Year Research, Development and Demonstration Plan:

- Durability (of catalysts and membrane electrode assemblies)
- Cost (of catalysts and membrane electrode assemblies)
- Performance (of catalysts and membrane electrode assemblies)
- Start-up and Shut-down Time and Energy/Transient Operation

Technical Targets

This project synthesizes novel extended thin film electrocatalyst structures (ETFECs) and incorporates these catalysts into electrodes with and without carbon for further study. The project has targets outlined in the Multi-Year Research, Development and Demonstration Plan for both electrocatalysts for transportation applications (Table 3.4.12) and membrane electrode assemblies (MEAs) (Table 3.4.13). The specific targets and status of highest relevance are presented in Table 1.

TABLE 1. Technical Targets for Electrocatalysts for Transportation Applications

Characteristic	Units	2010/2015 Targets	Status
Electrochemical Area Loss	%	<40%/<40%	
Mass Activity (150 kPa H ₂ /O ₂ 80°C 100% RH)	A/mg-Pt @ 900mV	0.44/0.44	0.33
Specific Activity (150 kPa H ₂ /O ₂ 80°C 100% RH)	μA/cm ² -Pt @ 900 mV	720/720	800-1,300

RH – relative humidity

Fiscal Year (FY) 2011 Objectives

- Produce novel catalysts based on extended Pt surfaces with increased activity and durability.
- Further increase electrochemically available surface area (ECA) and mass activity of extended surface catalysts.
- Effectively incorporate extended Pt catalysts into more traditional dispersed electrodes for mass transport/water management.
- Demonstrate and validate models for catalysts and electrodes based on extended surfaces.

FY 2011 Accomplishments

- Synthesized novel ETFECs that routinely surpass DOE 2015 target for specific activity.
- Demonstrated ETFECs with ECA as high as 40 m²/g_{Pt} and mass activities of 330 mA/mg_{Pt} far beyond the surface area of most extended surface catalysts with a mass activity approaching the 2015 DOE target.
- Demonstrated significantly improved durability of ETFECs towards potential cycling in rotating disc electrode (RDE) studies for both the Pt dissolution (0.6-1.0 V) and carbon corrosion region (1.0-1.6 V).

- Incorporated carbon into electrode structures that contain ETFECS while maintaining durability and activity.
- Demonstrated high specific activities of ETFECS in fuel cells.

Introduction

Pt remains a primary limitation for the widespread commercialization of polymer electrolyte fuel cells. To date, approaches looking to replace Pt with a non-platinum-group metal have met with limited success. “Thrifting” of Pt (i.e., ultra-low Pt loadings) seems to be the most likely (near-term) option for meeting cost, performance and durability targets. Typical Pt catalysts for fuel cell applications are small nanoparticles (such as cubooctahedron) that have high surface areas, and therefore significant fractions of Pt atoms are surface accessible. Clearly, having as many Pt atoms on the surface as possible is advantageous. However, catalytic activity and durability of extended surfaces can outweigh the surface area advantages of smaller particles, particularly if these advantages can be maintained at thin wall thickness, as highlighted by the promising work done on nanostructured thin film catalysts based on Pt or Pt alloys at 3M [1] and Pt and Pt alloy nanotubes at UC Riverside [2]. The synthesis of catalysts with high mass activity and the effective implementation of these catalysts in high performance, durable and robust MEAs will help enable fuel cell commercialization on a significant scale.

Approach

Our approach involves synthesizing novel ETFECS using either a nanostructured support material such as carbon nanotubes (CNTs), metal oxide nanoparticles, or perylene red nanowhiskers, or a sacrificial metal template. Pt is deposited on these materials either through

vapor deposition (including sputtering and atomic layer deposition [ALD]) or solution deposition (including galvanic displacement). Our goal is to produce nanostructures with thin, continuous films of Pt because similar structures have shown high catalytic activity and durability. The materials synthesized are characterized by several techniques with a strong focus on microscopy and electrochemistry. To date, extended surface catalysts have not been demonstrated in traditional, thick catalyst layers that include Nafion® and have been shown to exhibit good tolerance to a wide range of operating conditions including cold-start. The novel catalysts produced in this project are being implemented in thick, dispersed electrodes to investigate the production of high performance, robust electrodes from these materials. Modeling is being used in support of our catalyst synthesis studies and our electrode studies, extending established models involving wetting of Pt on supports, simulating electrode architecture, and evaluating criteria that impact electrode performance.

Results

In the past year, we added a number of additional substrates to our studies probing supports as extended surface Pt hosts. Included on our list of substrate nanomaterials to date are: carbon nanotubes, inorganic oxides, metals, and perylene red whiskers. Examples of novel templates synthesized this past year are shown in Figure 1.

In the area of Pt deposition, we focused on sputtering, ALD, and spontaneous galvanic displacement (SGD). Sputtering remains an area of interest, as we and 3M [1] have shown it to be a viable technique for depositing thin, continuous Pt layers. We have focused on deposition onto mats and short (>2 μm) vertically aligned CNTs. Transmission electron microscopy close-ups of Pt sputtered CNT mats show a transition between discrete particles and continuous Pt coating. These micrographs suggest that continuous coatings can be obtained at thicknesses of ~2 nm. Unfortunately, our ability to generate these

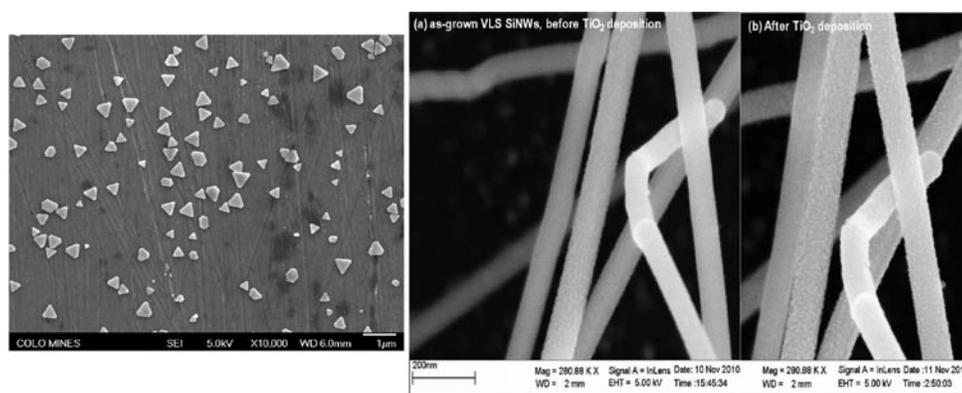

FIGURE 1. Ag nanoplatelets synthesized by solvothermal process (left); SiNWs synthesized by vapor-liquid-solid process (center); after TiO_2 deposition by ALD (right).

materials consistently and in higher yields has been poor. We have continued to investigate ALD for its ability to produce thin continuous Pt films. The most promising results have focused on using TiO_2 as a bonding layer. We found that a minimum thickness of TiO_2 followed by thermal treatment (annealing) results in the conversion of amorphous TiO_2 to anatase. The anatase form showed the fastest and most consistent Pt nucleation rates and is now being explored at ultra-thin (>5 nm) coating thicknesses and on nanostructured substrates. In the area of SGD we used Ag and Cu nanowires and Ag nanoplates as templates for Pt displacement and performed studies that have also included Pd or Au.

Our electrochemical characterization and electrode studies made significant strides in the past year. We established agreement with literature and demonstrated a high degree of reproducibility. We quantified the increases in specific activity from our novel materials and showed reasonably high surface areas (up to $40 \text{ m}^2/\text{g Pt}$) in ETFECS. While a few studies with CNTs were performed, our primary focus of electrochemical characterization was on materials synthesized by SGD, because we obtained higher yields and higher performance with these materials. A select portion of our data is highlighted in Figure 2. The three different colors/symbols represent a systematic series of novel materials based on SGD of either Cu or Ag nanowires investigating features including: reactant delivery rate, stoichiometry, temperature, reaction solvent, and post-processing. While we commonly surpass the DOE 2015 target for specific activity ($720 \mu\text{A}/\text{cm}^2 \text{ Pt}$), highlighted in Figure 3, we have not yet achieved the 2015 target for mass activity. Although extended surface catalysts have typically

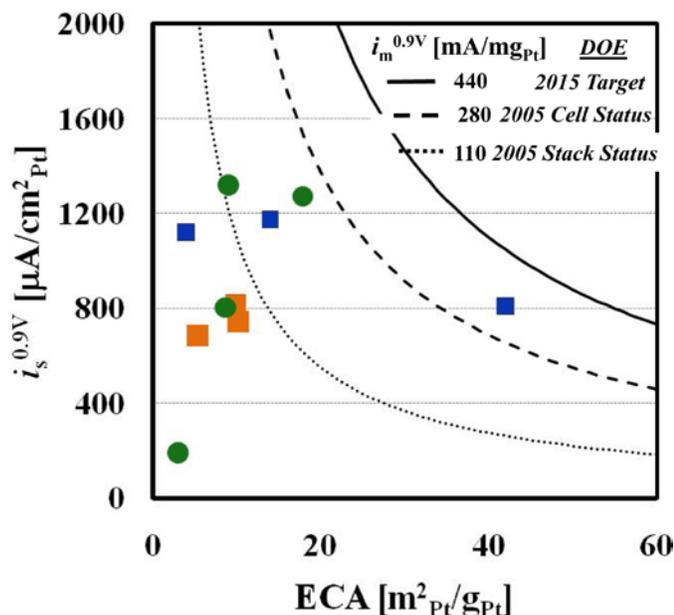

FIGURE 2. Specific activity vs. ECA for SGD ETFECS at NREL. Lines of constant mass activity shown as well.

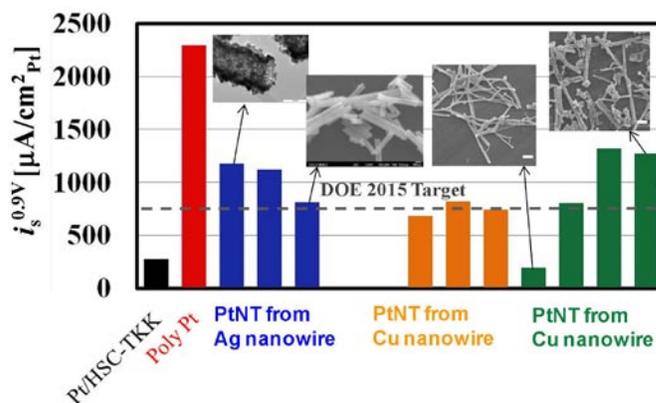

FIGURE 3. Specific activity of ETFECS compared to traditional Pt/C and polycrystalline Pt disc.

been limited to ECAs around $10 \text{ m}^2/\text{g Pt}$ we demonstrated ETFECS with ECA up to $\sim 40 \text{ m}^2/\text{g Pt}$. This high ECA material resulted in a novel catalyst with mass activity of $330 \mu\text{A}/\text{g Pt}$, approaching the $440 \mu\text{A}/\text{g Pt}$ DOE 2015 target. Continued investigations will seek to further increase both specific activity and ECA.

Beyond the improvements in electrochemical properties determined for the SGD ETFECS already highlighted, we also explored the impact of carbon incorporation on the electrochemical performance of these materials, tested the materials in fuel cells, and investigated the durability of these materials. All of these studies showed the promise of extended surfaces as novel fuel cell catalysts. Highlights from our studies are shown in Figure 4. The specific and mass activities of our ETFECS have essentially no impact on the observed specific and mass activity. Normalized ECAs show that traditional catalysts, as expected, show much poorer durability with potential cycling. Similar results were observed in the Pt dissolution region ($0.6\text{-}1.0$ V) in similar potential cycling studies.

Conclusions and Future Direction

We demonstrated for the first time conformal Pt coatings on CNTs and Pt nanostructures from Cu nanowires. We performed controlled growth of CNTs. We investigated Pt ALD, sputtering, SGD and other solution based routes as Pt deposition techniques. Future work, broken down by topical area, includes:

Templates/Cores:

- Metal oxide substrate development.

Pt Deposition:

- SGD process further optimization focusing on post-processing parameters.
- ALD studies investigating Pt growth on carbon and with reduced thickness/decreased nucleation cycles.

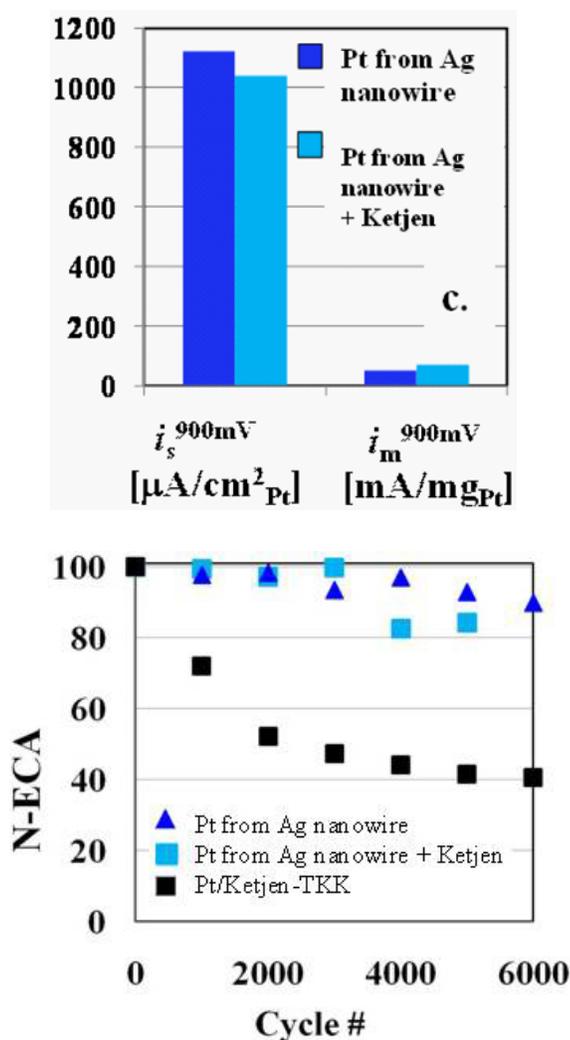

FIGURE 4. Specific and mass activities of ETFECS with and without carbon (top), stability to potential cycling from 1.0-1.6 V (carbon corrosion region), (bottom).

Electrode Studies:

- Electrochemical (RDE) durability screening of ETFECS as a function of initial ECA.
- Incorporation of highest performing catalyst ($330 \text{ mA}/\text{mg}_{\text{Pt}}$) into electrode studies.
- Expanded MEA fabrication and fuel cell testing of ETFECS.

Modeling:

- Advancement of models to electrode structures incorporating model ETFECS – PtNT of 150 nm diameter, 2 micron length.
- Expansion of porous electrode models to ETFECS incorporated electrodes.

Project Start Date: September, 2009
Project End Date: September, 2013

Fiscal Year (FY) 2011 Objectives

- Fundamental understanding of the oxygen reduction reaction on multimetallic PtM (M = Co, Ni, Fe, Mn, Cr, V, and Ti) and PtM₁N₂ (M₁ = Co or Ni; N₂ = Fe, Mn, Cr, V, and Ti) materials.
- Develop highly-efficient, durable, nanosegregated Pt-skin PtM and PtM₁N₂ catalysts with ultra-low Pt content.
- Develop highly-efficient and durable Au/PtM₃ nanoparticles with ultra-low Pt content.
- Find relationships between activity/stability of well-characterized bulk alloys and real nanoparticles.
- Develop novel chemical and physical methods for synthesis of monodispersed PtM and PtM₁N₂ alloy nanoparticles and thin metal films.
- Resolve electronic/atomic structure and segregation profile of PtM and PtM₁N₂ systems.
- Resolve composition effects of PtM and PtM₁N₂ systems.
- Demonstrate mass activity and stability improvement of PtM and PtM₁N₂ alloy nanoparticles.
- Use computational methods as the basis to form any predictive ability in tailor making binary and ternary systems to have desirable reactivity and durability properties.

Technical Barriers

This project addresses the following technical barriers from the Fuel Cells section (3.4.5) of the Hydrogen, Fuel

Cells and Infrastructure Technologies Program Multi-Year Research, Development and Demonstration Plan:

- (A) Durability
- (B) Cost
- (C) Performance

Technical Targets

This project is conducting fundamental studies of the oxygen reduction reaction on Pt-based PtM (M = Ni, Co, Fe, Cr, V, and Ti) binary and PtM₁N₂ (N, M = Fe, Co, and/or Ni) catalysts as well as on Au/Pt₃M ternary nanoparticles. Insights gained from these studies will be applied toward the design and synthesis of highly-efficient, durable, nanosegregated Pt-skin catalysts with ultra-low Pt content that meet or exceed the DOE 2015 targets (Table 1).

TABLE 1. DOE 2015 Targets

Specific activity @ 0.9 V _{iR} -free: 720 mA/cm ²	PGM total content: 0.2 g/kW
Mass activity @ 0.9 V: 0.44 A/mgPt	Total loading: 0.2 mg/cm ²
Catalyst support loss: <30%	Durability w/cycling (80°C): 5,000 hrs

V_{iR} – volt internal resistance; PGM – precious group metal

FY 2011 Accomplishments

- Synthesized wide range of bi/multimetallic nanoparticles with controlled size and composition by colloidal organic solvo-thermal approach.
- Developed vapor deposition/annealing methods to make stable and active Pt thin metal film (1-7 atomic layers) on Pt₃Ni substrate.
- Established relationships between the morphology/thickness of Pt atoms in skeleton structure and stability/activity of the catalysts: Pt film can both effectively protect Ni from dissolution and provide superior catalytic activity (x6 vs. Pt).
- Developed experimental protocol to synthesize PtNi/C nanoparticles with Pt multilayered “skin” (2-3 monolayers, ML) that are mimicking stability/activity of thin metal film systems.
- In a membrane electrode assembly (MEA), for PtNi/C multilayered skin confirmed: (i) three times higher specific amperage (SA ~0.8 mA/cm²) than benchmark Pt/C catalysts and mass activity of ~0.35 A/mg_{Pt}; (ii) high durability, e.g., after 20,000 cycles activity, surface area loss was only 12% compared to ~40% for Pt/C.
- Performed composition optimization of ternary PtM₁N₂ catalysts.

- Established activity (stability) trends for bimetallic nanoparticles (NPs).
- Demonstrated that ternary alloys could provide additional tunability towards activity and stability.

Introduction

In the quest to make the proton exchange membrane fuel cell (PEMFC) a competitive force, one of the major limitations is to reduce the significant overpotential for the oxygen reduction reaction (ORR) and minimize dissolution of the cathode catalysts. Here, we report progress for FY 2011 in experimental and theoretical studies to addressing the importance of alloying Pt with *3d* elements ($M = \text{Ni, Co, Fe}$ etc.) and making a novel tailored nanostructure of $\text{Au/Pt}_3\text{M}$ in order to form catalytically active materials with so-called nanosegregated profile [1]. We have demonstrated that the nanosegregated surfaces are superior in both: exceptional catalytic activity for the ORR and higher stability of Pt surface atoms.

Approach

To address the challenges that are listed as the DOE targets for the Fuel Cell Technologies Program we rely on our materials-by-design approach [2,3]. This involves four major steps: (i) advanced synthesis of novel nanoscale materials, which enables control of their size, structure and composition; (ii) characterization of atomic and electronic properties by ex situ and in situ surface characterization techniques and theoretical methods; (iii) resolving the surface electronic and crystal structures at atomic/molecular level that govern efficient kinetics of the ORR; and (iv) synthesis/fabrication (scale up) of the highly efficient nanoscale materials, which are guided by the fundamental understanding of structure-function relationships.

Results

From Model Thin Films to Real Pt-Skin PtNi Nanoparticles. The term Pt-skeleton has been coined to describe unique Pt structure that remains on the surface of bi(multi)-metallic alloys after dissolution of non-Pt atoms from the near-surface region in acidic environments [3]. On the other hand, the term Pt-skin has been used to describe another unique formation of Pt surface atoms that is formed after thermal treatment of bimetallic alloys due to tendency of Pt to have complete segregation over Pt_3M systems. In some cases, an oscillatory concentration profile with 100% Pt in the first layer is counterbalanced by depletion of Pt in the second layer, which is followed by enrichment of Pt in the third layer. Alloys with such segregation profile in near surface region we term nanosegregated systems, and they have been found to have superior catalytic properties for the ORR [1]. Particularly,

extended Pt_3M electrodes with Pt-skin surfaces are more active for the ORR than the corresponding Pt-skeleton structures [4]. In the previous FY 2010 report, we pointed out that the skeleton-like structure of $\text{Pt}_{50}\text{Ni}_{50}/\text{C}$ catalyst, formed by dissolution of the surface/subsurface Ni atoms, has the highest specific (4.0 mA/cm^2) and mass ($1.5 \text{ A/mg}_{\text{Pt}}$) activities for the ORR compared to the other $\text{Pt}_x\text{Ni}_{1-x}$ NPs. In the mean time, we have revealed that the concentration profile formed after leaching out of *3d* element from $\text{Pt}_x\text{Ni}_{1-x}$ catalysts indicated skeleton type of surface structure, whose thickness depends on the ratio between Pt and Ni [1]. In this report, we summarize the results that are providing both fundamental insights required for efficient transformation of the Pt-skeleton to more active Pt-skin morphology, which we used as guiding principles that have led to the synthesis of an advanced PtNi nanocatalyst with the optimized Pt-skin type of surfaces. In order to evaluate correlation between the thickness of Pt-skeleton overlayer and catalytic properties we used physical vapor deposition method to prepare well characterized Pt-skeleton surfaces over the $\text{Pt}_{50}\text{Ni}_{50}$ substrate, which was found to be the most active bimetallic catalyst. As depicted in Figure 1, the as-sputtered Pt films consisted of randomly distributed Pt atoms, which simulate the Ni-depleted Pt-skeleton overlayers. Figure 1 also shows that the optimal activity for the ORR (improvement factor 2.5) is observed on the surface covered by ca. 3 MLs of Pt, which is in line with the previous results on polycrystalline Pt_3M bulk alloys with the skeleton type of surfaces. Reduced enhancement was observed for thicker Pt films, e.g., improvement factor of 1.7 for 5 ML of Pt, while the specific activity measured for the 7 ML film was close to that of poly-Pt. In order to transform the Pt-skeleton morphology to more active Pt-skin, we applied a moderate thermal treatment at 400°C , which was previously optimized for bimetallic NPs [5]. Such treatment induced relaxation of low-coordinated Pt surface atoms and formation of energetically favorable adlayer with higher coordination of surface atoms. Electrocatalytic properties and structural characterization of such adlayer revealed the formation of Pt-skin, which was verified by the suppressed H_{upd} region and substantial positive shift of the Pt-OH_{ad} peak as well as by ~5-times increased in specific activity of the ORR (Figure 1).

The knowledge obtained from the well-defined systems is then used to optimize the catalytic properties of the $\text{Pt}_{50}\text{Ni}_{50}$ NPs with skeleton type of surfaces mentioned above [FY 2011 Ref. 3]. Further modification of near-surface morphology was obtained by a subsequent annealing of the skeleton-type of NPs at 400°C . This treatment has facilitated relaxation of low-coordinated surface atoms and transition of the particle surface morphology into Pt-skin type. Combined scanning transmission electron microscopy (STEM) and energy dispersive X-ray (EDAX) analyses revealed a concentration profile and the thickness of the Pt overlayer. It has been found that the particle core has

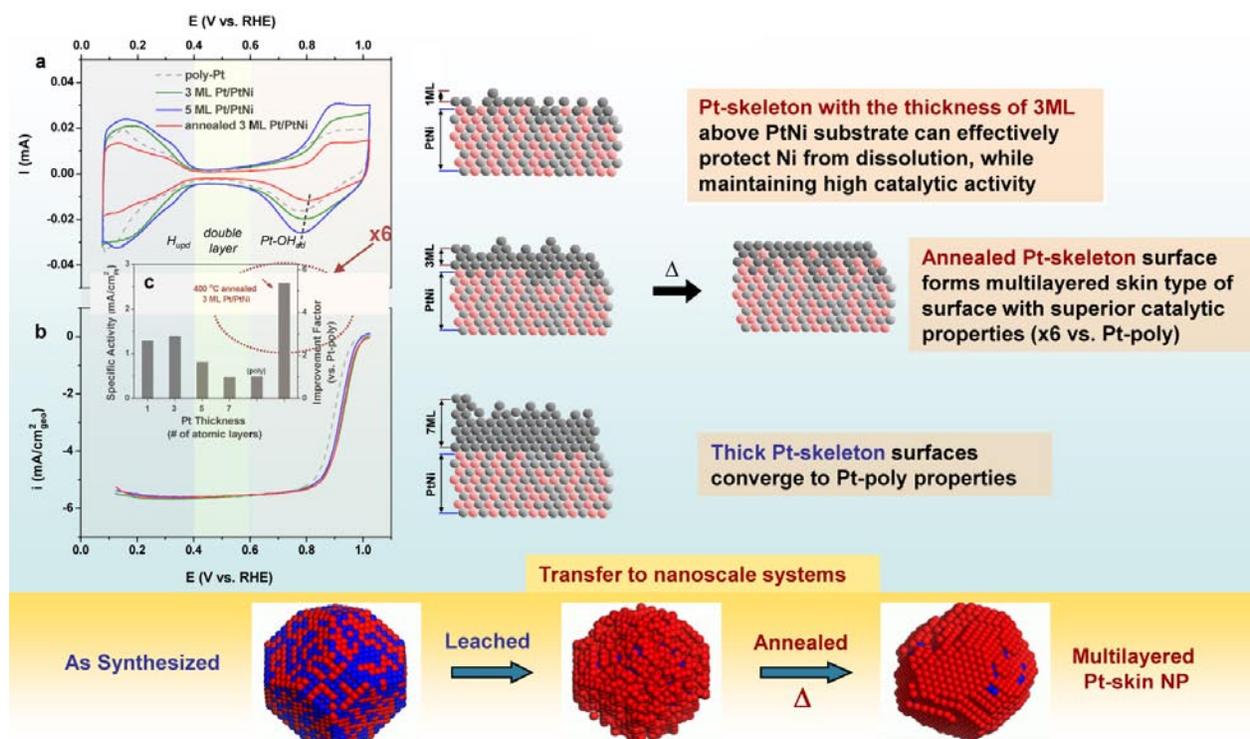

FIGURE 1. Electrochemical studies on the Pt thin films deposited over PtNi substrate by rotating disk electrode (RDE): (a) cyclic voltammograms, (b) polarization curves and (c) summary of specific activities and corresponding improvement factors (vs. polycrystalline Pt surface) for the Pt films of various thicknesses. Cyclic voltammograms were recorded in Ar saturated 0.1 M HClO₄ electrolyte with a sweeping rate of 20 mV/s. Polarization curves were recorded in the same electrolyte under O₂ saturation with a sweep rate of 20 mV/s. Specific activities were presented as kinetic currents normalized by electrochemical surface areas obtained from integrated H_{up,d}, except that for the annealed 3 ML Pt/PtNi surface it was based on CO_{ad} stripping polarization curve. Schematic representation of surface morphology transformations for PtNi NP.

Pt₅₀Ni₅₀ composition, while the thickness of the Pt overlayer is about 2-3 ML; schematic representation is depicted in Figure 1. Based on electrochemical characteristics we concluded that these nanoparticles have typical Pt-skin properties, i.e., suppressed H_{up,d} region and superior catalytic activity towards the ORR: SA=1 mA/cm² at 0.95 V. In addition, PtNi NPs with multilayered skin surfaces are found to have excellent durability after 30,000 cycles between 0.5 to 1.1 V [1].

Finally, catalytic activity and stability of these NPs were tested in an MEA (General Motors R&D facilities). It is found that PtNi/C NPs with Pt multilayer skin surfaces have 3x higher specific activity (0.8 mA/cm²) than benchmark Pt/C and mass activity of 0.35A/mg_{Pt}. Furthermore, after 20,000 cycles the activity loss was only 12%, while commercially available Pt/C and bimetallic catalysts suffer loss of 30-50%. Therefore, we concluded, that Pt₅₀Ni₅₀/C NPs with multilayered Pt skin meet DOE 2015 targets for specific activities and exceed anticipated targets for stability.

Characterization, Activity and Stability of Ternary Systems. Organic colloidal solvo-thermal approach was developed to synthesize Pt₃MN (N,M = Fe, Co, and/

or Ni) ternary alloys that potentially could be used as the cathode materials in PEMFC systems. Although many types of catalysts have been synthesized, for our purposes here we present only the results for the most promising ternary catalysts. As summarized in Figure 2, the transmission electron microscope (TEM) image depicts highly uniform particle size of the Pt₃NiCo NPs, with the average particle size of ~6 nm. On the other hand, the analysis of high angle annular dark field (HAADF) and STEM data indicated homogenous distribution of the alloying elements. The X-ray diffraction analysis showed single crystal phase for all NPs, confirming the homogeneous alloy composition. It is obvious, therefore, the solvo-thermal synthesis brings high level of control of the crucial parameters such as homogenous distribution of particle size and composition profiles. We demonstrate further that these types of NPs may possess desirable catalytic activity for the ORR. For example, Figure 3 shows that acid-leached Pt₃CoNi NPs have the highest specific (0.85 mA/cm²) and mass (0.3 A/mg_{Pt}) activity at 0.95 V. These results strongly suggest that alloying Pt with the 3d elements can provide additional tunability towards the activity of Pt-based alloy catalysts. We anticipate that catalytic activity of the PtMN NPs with skeleton type of

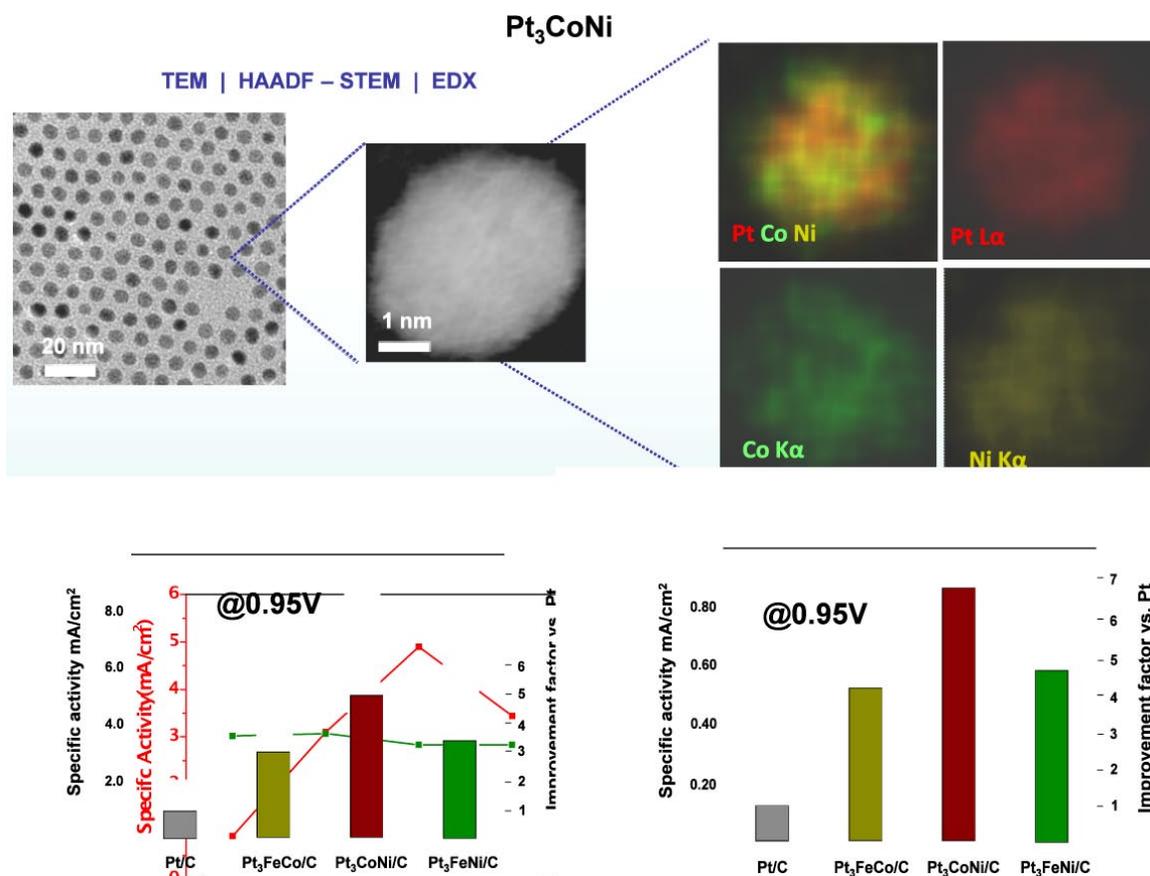

FIGURE 2. TEM, HAADF-STEM, EDAX and electrochemical characterization of Pt₃CoNi ternary alloy nanoparticles. Bar graphs: the summary of specific and mass activities of Pt₃MN NPs measured by rotating disk electrode in 0.1M HClO₄ at 0.95 V, 1,600 rpm and 20 mV/s.

surfaces could be further improved by the temperature-induced formation of the Pt-skin morphology.

Shape Controlled Core/Shell Ternary Nanoparticles.

In addition to ternary systems mentioned above we develop an approach toward design and synthesis of an advanced three component system with core/shell structure. A ternary catalyst with Au core and bimetallic Pt₃Fe shell is being developed for the ORR. Tailored Au/Pt₃Fe structure has been optimized through the studies of well-defined thin film surfaces and then synthesized by organic solvo-thermal method. The morphology control and preferred composition profile were achieved through epitaxial growth of Pt₃Fe over 7 nm Au seed. Figure 3 depicts the morphology, structure, and size of the Au/Pt₃Fe NPs with the average size of 10 nm. High resolution transmission electron microscopy (HRTEM) images reveal that while both Au NPs and Au/Pt₃Fe NPs possess an icosahedral-like shape, Pt₃Fe particles have a characteristic cubo-octahedral shape. The composition profile of multimetallic particles, established from HAADF-STEM imaging and elemental mapping, signify that the Au seed is surrounded by both Pt and Fe atoms. As shown in Figure 3, these multimetallic Au/Pt₃Fe NPs possess both the high catalytic activity and the superior

durability, with mass activity enhancements of more than one order of magnitude over Pt catalysts. Furthermore, TEM images and electrochemical capacitance analysis of cyclic voltammograms acquired before and after durability testing (60,000 cycles in the potential range between 0.6 and 1.1 V in oxygen saturated electrolyte) unambiguously revealed that in contrast to Pt₃Fe/C and Pt/C no significant loss in electrochemically active surface area (360 vs. 340 cm²/mg_{Pt}) or specific activity (1.5 vs. 1.4 mA/cm²) before and after cycling was observed for Au/Pt₃Fe/C. The increased activity was explained based on electronic effects induced by alloying Pt with Fe, the enhanced durability was achieved by the tailored morphology of icosahedral NPs and unique compositional profile of three alloying components [2]. The reported result for the core-shell type of catalysts has opened new avenues for synthesis of highly active and stable cathode catalysts for the PEMFC applications.

Conclusions and Future Directions

- PtM and PtM₁N₂ NPs cathode catalysts obtained from the organic solvo-thermal synthesis exhibit superior activity and stability than those prepared by the

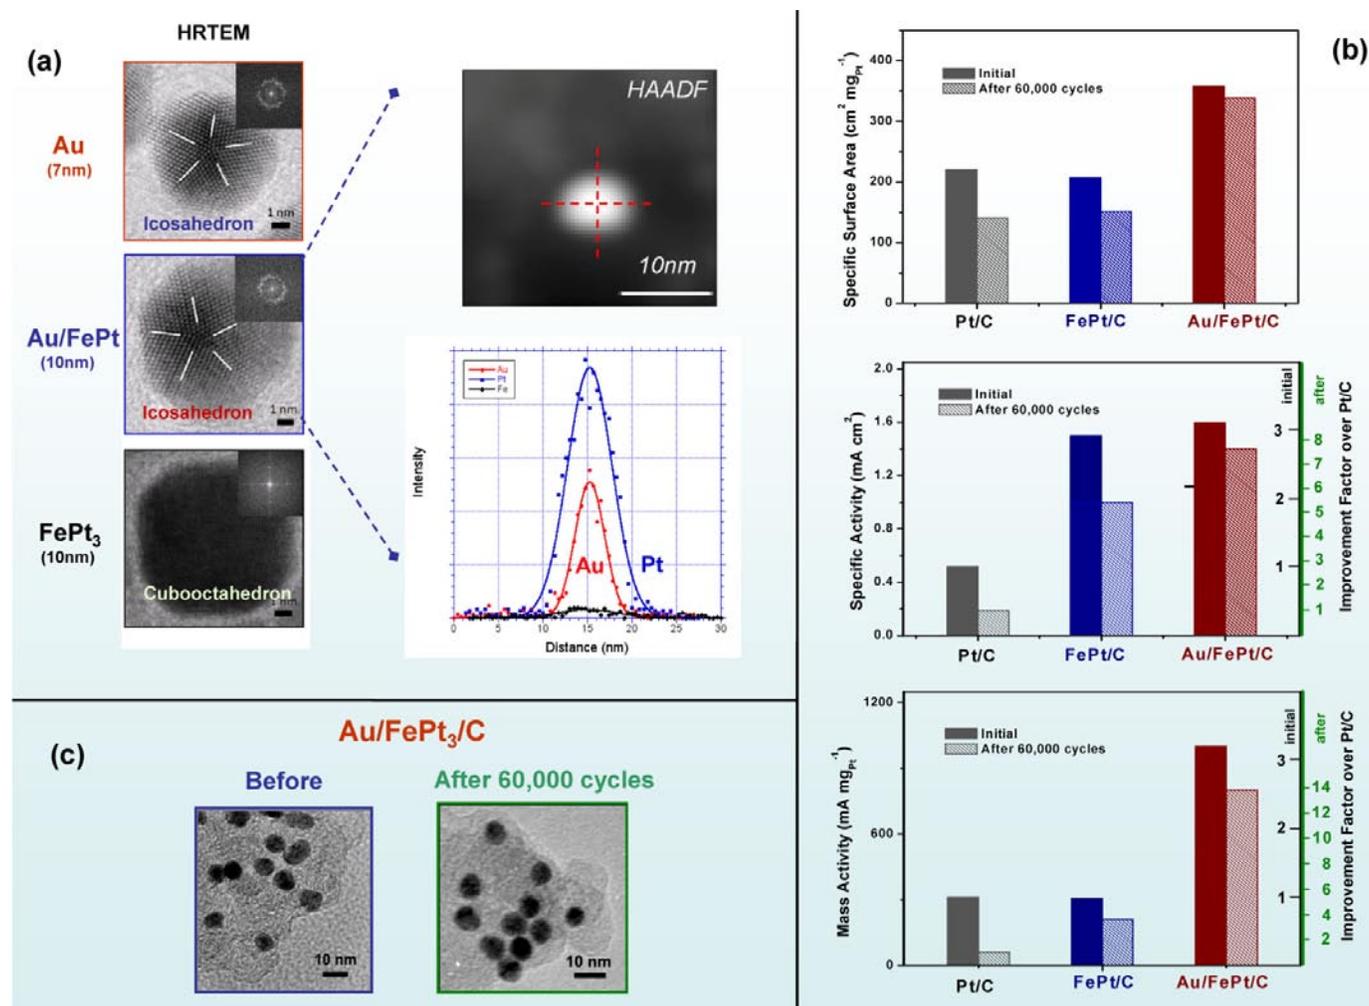

FIGURE 3. Ternary core shell Au/FePt catalyst: (a) HRTEM characterization of Au, Au/FePt and FePt₃ nanoparticles. HAADF and energy dispersive X-ray characterization of Au/FePt NP, which confirms core/shell structure. (b) Electrochemical characterization by RDE at 0.9 V in 0.1M HClO₄ for Pt/C, Pt₃Fe and Au/FePt catalysts. conventional methods. The methods of synthesis of PtNi NPs with highly active and stable Pt-skin morphology is developed.

- Significant mass activity and durability improvement are obtained for Pt-skin PtNi/C NPs with multilayered (2-3 atomic layers) Pt skin in both rotating disk electrode configuration and MEA. Advanced theoretical modeling methods are developed for resolving nanosegregated structures.
- Ternary systems possess high activity and stability but understanding the mode of action of two three-dimensional elements added to the Pt host has yet to be addressed.
- In collaboration with industrial partners, further testing in MEA of the most promising multimetallic catalysts is planned as well as scaling up synthesis methods for the larger scale production of the most active catalysts.

Subcontractors:

- ¹ Massachusetts Institute of Technology (MIT),
Cambridge MA
- ² Johnson Matthey Fuel Cells (JMFC), London, England

Project Start Date: July 1, 2009
Project End Date: September 30, 2013

- (A) Performance
- (B) Cost
- (C) Durability

Technical Targets

Progress toward meeting DOE fuel cell electrocatalysts technical targets is shown in Table 1.

FY 2011 Accomplishments

- Demonstrated the stabilization mechanism of core-shell NPs by which a Pt ML shell is being protected by the cores.
- Demonstrated synthesis of hollow Pd NP with hollow-induced lattice contraction enhancing the ORR activity on a Pt ML.
- Demonstrated electrodeposition of Pd nanorods and nanowires on functionalized carbons as a support for high activity and durability of Pt ML catalysts. The performance of a 5 cm² MEA shows an excellent activity/stability.
- Demonstrated synthesis of one-dimensional interconnected Pt NPs on amine-functionalized multi-wall carbon nanotubes (MWCNTs).
- Demonstrated synthesis of tetrahedral Pd NPs – an excellent low-Pd content support for a Pt monolayer.
- Developed high performance Pt monolayer on non-noble metal core-noble metal shell NP –Pt/Ir/Ni/C-electrocatalyst. 1 ML Pt and 2MLs Ir around Ni core.
- Fuel cell stability tests of Pt/Pd₉Au₁/C electrocatalysts show no dissolution or loss in activity during 100,000 and 200,000 potential cycles. This electrocatalyst is ready for applications.

Fiscal Year (FY) 2011 Objectives

Developing high-performance fuel cell electrocatalysts for the oxygen reduction reaction (ORR) comprising contiguous Pt monolayer (ML) on stable, inexpensive metal or alloy:

- Nanoparticles (NP)
- Nanorods; Nanowires
- Carbon nanotubes (CNT)

Technical Barriers

This project addresses the following technical barriers from the Fuel Cells section of the Fuel Cell Technologies Program Multi-Year Research, Development and Demonstration Plan:

TABLE 1. Progress toward Meeting DOE Fuel Cell Electrocatalysts Technical Targets

Characteristic	Units	Target	Target	Achieved
		2010	2015	2010
Platinum Group Metal (PGM) Total Loading	mg PGM/cm ² electrode area	0.3	0.2	0.11
Mass Activity	A/mg Pt @ 900 mV _{iR-free}	0.44	0.44	2.8 (Pt on Pd nanowires)
Specific Activity	μA/cm ² @ 900 mV _{iR-free}	720	720	1,100 (Pt on Pd rods)
PGM Mass Activity				0.58 (Pt on hollow Pd)
Durability				No loss in activity in 200,000 cycles Pt/Pd(Au) in fuel cell test

iR-free – internal resistance-free

Introduction

Building on the advances made in the last decade in fuel cell electrocatalysis yielding improved electrocatalysts, and increasing our understanding of the kinetics of the ORR, further developments during the last two years lessened some technological difficulties that used to hamper the automotive applications of fuel cells. The understanding of the properties of Pt ML electrocatalysts, and of a broader class of core-shell electrocatalysts, Pt alloys, dealloying approach, and of complex influence of the NP size and shape on the catalyst's activity made it possible to optimize the properties of certain classes.

Approach

Following our position on the role of OHads on Pt on the ORR from the late eighties, and our recent finding of significant weakening of binding energy of oxygen (BE-O) on the (111) facet compared to the extended surface due to nanoscale induced in-plane lattice contraction, our approach focuses on having surfaces with the high coordination (111) facets. These surfaces are most conducive to the ORR on NPs. In addition, they are less prone to dissolution than low-coordinated edges, defects, and less close-packed facets. Because the ORR rate on Pt is OH-, or O-desorption limited, lowering BE-O enhances the ORR activity. Therefore, smooth, lattice contracted (111) like surface structures are needed to achieve durable high-ORR activity.

Therefore, we synthesized the supporting NPs having predominantly highly coordinated atoms that exist on nanorods, nanowires, smooth NPs, hollow Pd spheres, single crystalline NPs with predominantly (111) facets. We used the electrodeposition to make Pd nanorods on C NPs, Toray paper (5 cm²), and gas diffusion layer (GDL).

Results

Pt Monolayer on Electrodeposited Pd Nanorods, Nanowires Electrocatalysts

The nanorods and nanowires having smooth surfaces are attractive supports for Pt monolayer. Electrodeposition facilitates a better Pd utilization and a direct formation at the carbon surfaces that provides electrolyte access to a major part of the catalysts' surface and thus its best utilization. Figure 1 shows the polarization curve of 5 cm² electrode obtained electrochemically on Toray paper. Total PGM loading is 0.11 mg/cm².

Bimetallic IrNi Core Platinum Monolayer Shell Electrocatalysts

To further decrease the PGM content we synthesized the electrocatalyst consisting of a Pt monolayer placed on carbon-supported thermally treated IrNi core-shell NPs.

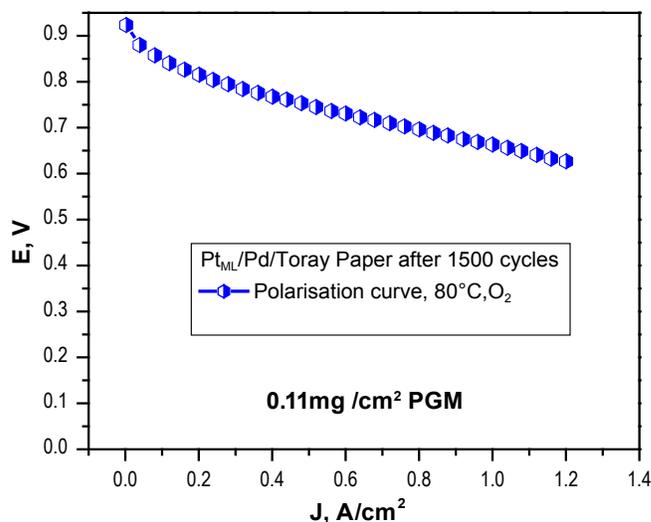

FIGURE 1. Polarization curve for the cell with 5 cm² cathode. The catalyst Pt_{ML}/Pd obtained electrochemically on Toray paper. Total PGM loading is 0.11 mg/cm².

The Pt mass activity of the Pt_{ML}/IrNi/C electrocatalyst obtained in a scale up synthesis is approximately three times higher than that of the commercial Pt/C electrocatalyst. The electronic and geometrical effects of the IrNi substrate on the Pt monolayer result in its higher catalytic activity than that of Pt NPs. The structure and composition of the core-shell NPs were verified using transmission electron microscopy and in situ X-ray absorption spectroscopy, while potential cycling test was employed to confirm the stability of the electrocatalyst (Figure 2).

Pt Monolayer on Hollow Pd NPs Electrocatalysts

Based on promising results obtained with hollow Pt NPs, we explored possibility to form hollow Pd nanoparticle support for a Pt monolayer. It is interesting to see whether hollow can induce a needed lattice contraction in an overlayer. Using Ni NPs as dissolvable template, we produced compact Pd hollow nanospheres. Excellent activity was found after deposition of a Pt monolayer: Pt+Pd+Au mass activity is 0.57 A mg⁻¹; Pt mass activity = 1.62 A mg⁻¹, specific activity = 0.85 mAcm⁻².

One-Dimensional Interconnected Pt NPs on Amine-Functionalized MWCNTs

MWCNTs were functionalized by amine groups in a Polyol synthesis. Further treatment involved rinsing in 6 M HCl and thermal treatment at 220°C. Excellent specific and mass activities were obtained (Figure 3). PGM mass activity is 1.4 times that of 40% Tanaka Kikinokogyo, while specific activity is 0.9 mA/cm².

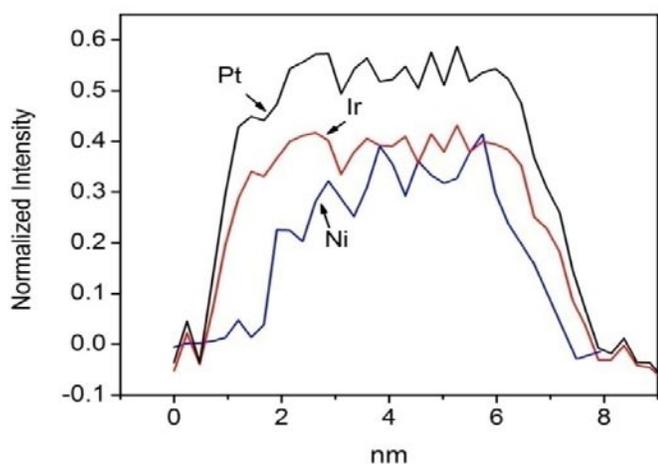

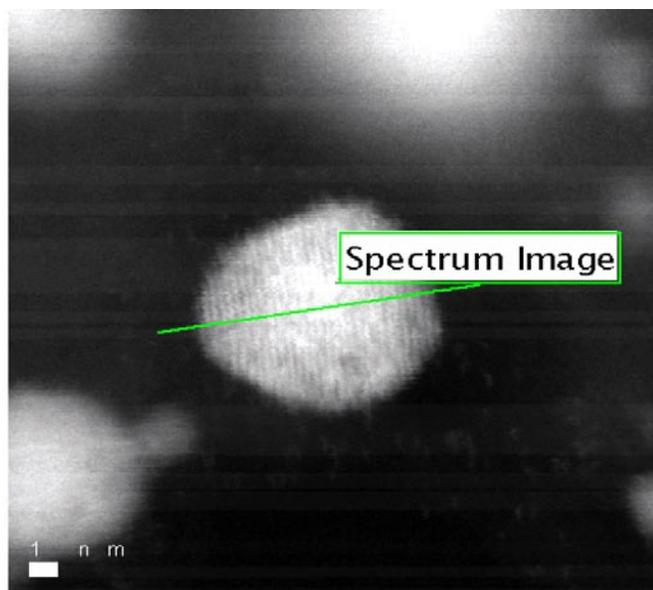

FIGURE 2. Bimetallic Ni-Ir Core Pt ML shell electrocatalysts after 50,000 potential cycles test. Upper panel: High angle annular dark field image of a single NP; Lower panel: Distribution of Pt and IrNi components in a single representative NP from M and L absorption edges. It is clearly shown that the core-shell structure of IrNi NP is maintained even after 50,000 cycles.

Fuel Cell Tests of the Pt_{ML}/Pd/C and Pt_{ML}/Pd₉Au/C at Toyota

Several stability tests of Pt/Pd/C and Pt/Pd₉Au/C catalysts involving potential cycling from 0.6 and 1.0 V; dwell time 10 sec; square-wave modulation; 80°C have been performed. High stability of Pt ML and a partial dissolution of Pd in some cases led to the mechanism of stability of core-shell electrocatalysts in which the shell is protected by the core. Pd dissolution precludes dissolution of Pt (cathodic protection effect) and more importantly, the contraction of Pt and Pd lattices, induced by loss of Pd, increases stability and activity of the catalyst – self-healing effect (Figure 4). Negligible loss in activity is observed in 100,000 cycles with Pt/Pd/C catalysts, while with the more stable Pt/Pd₉Au/C,

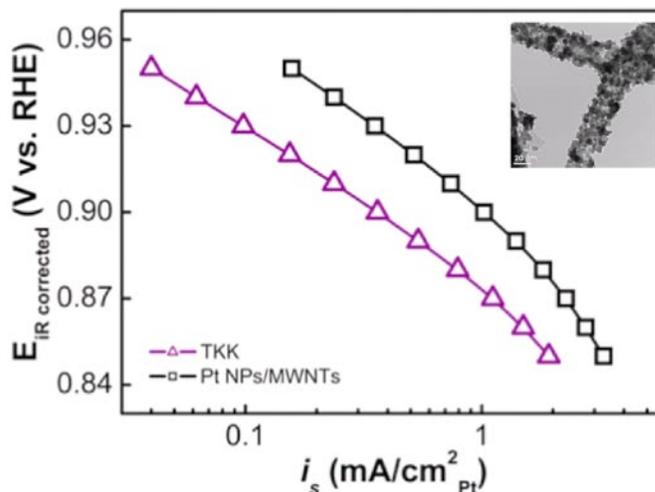

FIGURE 3. Polarization curve for the ORR on Pt interconnected NPs on MWCNTs compared with a commercial Pt/C catalyst. Insert: Scanning transmission electron microscopy image of the segment of CNT with the Pt deposit.

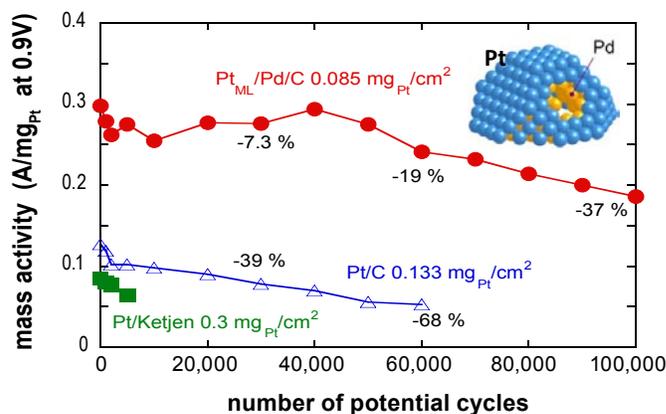

FIGURE 4. Accelerated stability fuel cell tests of the Pt/Pd/C and two commercial Pt/C cathode catalysts given for comparison. Potential cycling from 0.6 and 1.0 V; dwell time 10 sec; square-wave modulation; 80°C.

no loss is seen. Commercial Pt/C catalysts perish completely within 50,000 cycles. The Pt/Pd/C and Pt/Pd₉Au/C catalysts are ready for applications.

Conclusions and Future Directions

- Smooth surfaces, with highly-coordinated atoms, are suitable to support a Pt ML that yields very active catalysts.
- Pd nanowires were synthesized. Their thickness needs to be reduced and removal of surfactants simplified to obtain an excellent catalyst with a Pt ML.
- Electrodeposited NPs make excellent supports for Pt. Scale up of the cell for electrodeposition of Pd NPs

seems possible to the dimensions required for fuel cell stacks.

- Hollow Pd and Pt NPs are very attractive for further studies.
- Bimetallic IrNi core platinum monolayer shell electrocatalysts are highly promising for scale up syntheses and further reduction of PGM content (one ML of Pt and two MLs of Ir).
- The Pt/Pd₃Au₁/C electrocatalyst is ready for application in fuel cells for electric vehicles.

Future studies will focus on:

- Improve synthesis of Pd nanorods, nanowires, and Pd hollow NPs. (BNL, MIT, JMFC)
- Improve metallization and catalysation of CNTs, oxides, nitrides. (JMFC, MIT, BNL)
- Pd-Nb alloy NPs; start the work on Pd-W NPs and Pd-V. (BNL, MIT)
- Scale up of selected catalysts up to 20 grams. (JMFC, BNL)
- Scale up of electrodeposition on Toray paper and GDL to 50 and 500 cm² electrodes.
- MEA fabrication and tests.

Project Start Date: October 2009

Project End Date: October 2014

Fiscal Year (FY) 2011 Objectives

- Development of durable, high mass activity platinum group metal (PGM) cathode catalysts enabling lower cost fuel cells.
- Elucidation of the fundamental relationships between PGM catalyst shape, particle size and activity to help design better catalysts.
- Optimization of the cathode electrode layer to maximize the performance of PGM catalysts improving fuel cell performance and lowering cost.
- Understanding the performance degradation mechanisms of high mass activity cathode catalysts to provide insights to better catalyst design.
- Development and testing of fuel cells using ultra-low loading high activity PGM catalysts – validation of advanced concepts.

Technical Barriers

- PGM catalysts are difficult to synthesize in configurations other than quasi-spherical particles.
- PGM area specific activity may decrease with decreasing particle size.
- Durability may decrease with greater PGM surface area to volume ratios.

Technical Targets

The technical targets for catalyst loading are indicated in Table 1. These targets were formulated with the assumption that fuel cell durability and impurity tolerance would not be impacted by the decreased Pt loadings used in the fuel cells.

TABLE 1. Technical Targets: Electrocatalysts for Transportation Applications (Extracted from Table 3.4.12. Technical Plan. April 27, 2007)

Characteristic	Units	2005 Status		Stack Targets	
		Cell	Stack	2010	2015
PGM total content (both electrodes)	g/kW (rated)	0.6	1.1	0.3	0.2
PGM total loading	mg PGM/cm ² electrode area	0.45	0.8	0.3	0.2

FY 2011 Accomplishments

- Synthesis, structural, (high resolution transmission electron microscopy [HRTEM] and X-ray diffraction [XRD]) and electrochemical characterization of Pt Pd nanoplates completed.
- Synthesis structural, (HRTEM and XRD) and electrochemical characterization of Pt/ceria/carbons catalysts completed and published.
- Synthesis structural, (HRTEM and XRD) and electrochemical characterization of Pt polypyrrole nanowires completed and published.
- Thermal characterization of Pt/ceria/C catalysts completed and published.
- Theoretical model of Pt-Ni nanoparticles developed and published.
- Theoretical modeling of Pt nanotubes completed.
- Microstructural model of the catalyst electrode layer validated against experimental work.
- Pt nucleation growth study on carbon completed and published.

Introduction

Minimizing the quantity of Pt group metals used in polymer electrolyte membrane fuel cells (PEMFCs) is one of the remaining grand challenges for fuel cell commercialization. Tremendous progress has been achieved over the last two decades in decreasing the Pt loading required for efficient fuel cell performance. Unfortunately, the fluctuations in the price of Pt represent a substantial barrier to the economics of widespread fuel cell use.

Durability and impurity tolerance are also challenges that are tightly coupled to fuel cell Pt electrode loading. Traditional approaches to decreasing the amount of Pt required for good performance include:

- Increasing mass activity by decreasing Pt particle size by supporting on carbon.
- Alloy formulation Pt-Co, Pt-Cr alloys to improve mass activity.
- Increasing Pt utilization by optimization of electronic and ionic contact of the Pt particles.
- Improving conductivity of the electronic and ionic conducting constituents of the membrane electrode assembly.
- Improving reactant to and product mass transport away from the electroactive sites.

Recent novel approaches include the nanoengineering of core shell catalysts and Pt particles of unusual geometries such as nanowires/whiskers.

The success of the aforementioned approaches has been great; however further advances using such approaches have been hampered by a lack of underlining scientific understanding of the catalyst activity, particle growth mechanisms, and optimization strategies for designing composite electrodes.

Approach

Our approach to new PGM catalyst design is multi-tiered. We are designing new low platinum loading catalysts on novel support materials to improve fuel cell performance. Novel PGM shapes; nanoparticles, nanotubes and nanowires are being synthesized in a variety of sizes. We are using contemporary theoretical modeling and advanced computational methods to understand and engineer the new catalysts. We are also modeling and designing appropriate catalyst architectures to maximize the performance of our novel catalysts. Catalyst-support interactions and their effects on durability and mass activity are also investigated. We study and test the performance of the catalysts in electrochemical cells, single cell fuel cells and fuel cell stacks. The new catalysts are extensively characterized before and after fuel cell operation.

Results

We have improved our theoretical understanding of the Pt-Ni alloy catalyst system, a very promising catalyst system recently demonstrated to meet the DOE technical targets for catalyst activity for oxygen reduction. The structure, reactivity and stability of three different Pt-Ni alloys, PtNi, Pt₃Ni and PtNi₃ were studied using periodic density functional theory (DFT) calculations. The influence of the alloying component concentration on the catalytic activity of the platinum surface was studied by calculating equilibrium adsorption potentials for oxygen reduction reaction (ORR)

intermediates and by constructing free energy diagrams in the ORR dissociative mechanism network. In addition, the stability of these materials in aqueous environments was investigated in the terms of relative electrochemical dissolution shifts and by determining the most stable state of the surface as a function of pH and potential as represented in Pourbaix diagrams. The (111) surface of all three studied Pt-Ni alloys show improved oxygen reduction activity over Pt(111). The ORR overpotential was calculated to decrease as Pt (0.55 V) > Pt₃Ni (0.24 V) > PtNi₃ (0.19 V) > PtNi (0.15 V). Thus, it can be expected that the catalytic activity towards ORR will increase in the order Pt < Pt₃Ni < PtNi₃ < PtNi. Around 50% alloying with Ni induced the biggest change in activity. Shifts in the electrochemical dissolution potentials of the studied Pt-Ni alloys relative to platinum were estimated to be -0.27 V for PtNi₃, +0.13 V for Pt₃Ni and +0.30 for PtNi. Thus, among all studied materials PtNi is predicted to be the least susceptible to corrosion at similar pH and cell potentials.

The formation of Pt catalysts on active oxide supports may also improve activity and fuel cell durability. Highly crystalline ceria nanoparticles in porous carbon matrices were formed by the simple pyrolysis of cerium-loaded ion-exchange resins. The resulting cerium/carbon composite structures maintain the original bead or powder form of the precursor resins (Figure 1), with an increase in specific surface area. Incorporating Gd or Pr dopants with Ce in the resins provided uniform dispersions and equally small ceria crystallites upon pyrolysis, typically 1–2 nm (Figure 2). Highly active particles were obtained, as demonstrated by air light-off of the ceria/carbon composites as low as 200°C. The combination of the high pyrolysis temperature (1,000°C) and the controlled dispersion and stable environment provided by the ion-exchange resin precursors are key to provide highly crystalline and extremely small ceria particles

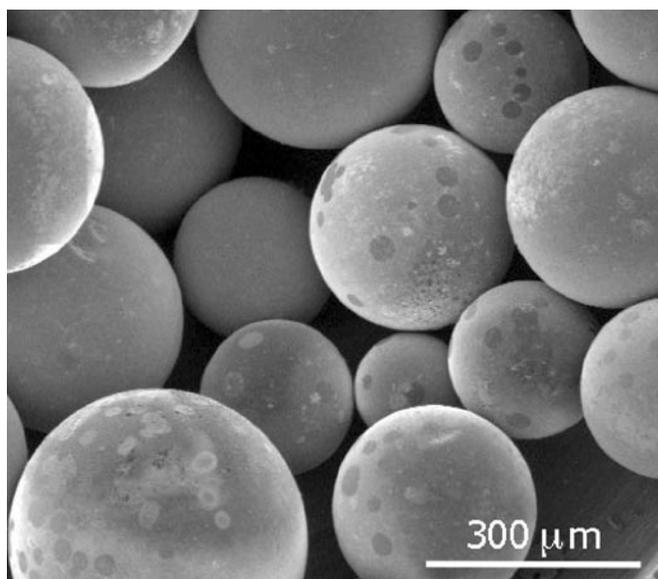

FIGURE 1. Scanning Electron Micrograph of Pyrolyzed IRC748 Beads

in a conductive carbon matrix. Various types of cation-exchange resins are considered and the best results are obtained with highly cross-linked or styrene-divinyl benzene matrices and cation chelating or weak acid functionalities.

One of the outstanding challenges in the wider deployment of PEMFCs is improving the utilization of Pt. While decreasing particle size improves accessibility of the Pt, it also destabilizes the Pt particles and leads to dissolution/re-precipitation and rapid grain growth. A parameter that is as yet poorly characterized is the number of nucleation sites on the carbon support. Increased nucleation site density could provide a valuable approach to improve Pt utilization. We have characterized the nucleation density by determining the number of particles per m^2 using HRTEM and energy dispersive X-ray spectroscopy (EDS). Ranges of metal loadings were explored to investigate their effect on the number of Pt particles on three types of carbon supports. It was concluded that the number of nucleation sites is relatively constant over the Vulcan family of carbon supports, see Table 2. However, activated carbons such as Norit SX-1G show much higher nucleation density.

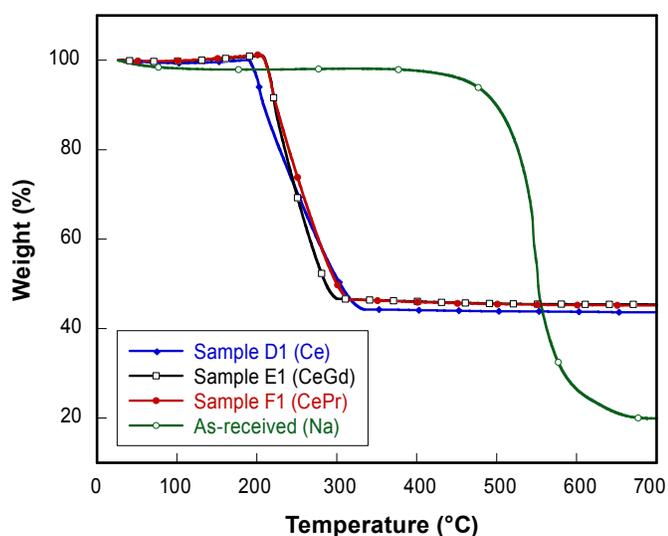

FIGURE 2. Air thermal gravimetric analysis of pyrolyzed IRC748 resins loaded with Ce (D1), Gd-doped Ce (E1), Pr-doped Ce (F1), and as-received Na form.

TABLE 2. Pt number density on Vulcan carbon derived from HRTEM analysis and EDS.

Catalyst	Pt wt%	Number of Pt particles/ m^2
Aqueous Impregnation Pt/Vulcan XC72	3.7	$1.20E+17$
E-TEK 10 wt% Pt/Vulcan XC72R	11.3	$1.04E+17$
Cabot 20 wt% Pt/Vulcan XC72	29.8	$1.01E+17$

Conclusions and Future Directions

- Pt/Ceria/catalyst research and development:
 - Improve Pt dispersion and scale up synthesis for fuel cell testing.
 - Calculate optimal MEA geometries.
 - Ionomer incorporation into catalyst layers and MEA optimization.
 - Fuel cell performance and durability testing.
- Pt/Pd nanoplatelet research and development:
 - Decrease nanoplate size by surfactant modification.
 - Scale up synthesis for fuel cell testing.
 - Incorporation into catalyst layers and MEA optimization.
 - Fuel cell performance and durability testing.
- Development of models and theory:
 - DFT model extension to nanoplates and nanowires.
 - Sintering model extension to include dissolution and reprecipitation.
 - Microstructural model application to novel catalysts fuel cell validation.

Project Start Date: August 31, 2009

Project End Date: August 31, 2013

Fiscal Year (FY) 2011 Objectives

1. Demonstrate that non-platinum group metal (non-PGM) catalysts can be used for oxygen reduction reactions (ORRs) in polymer-coated electrode structures based on polyelectrolyte membranes. (Year 1)
2. Incorporate catalysts into polymer binders of composite electrodes for the construction of membrane electrode assemblies (MEAs) to demonstrate that this is an effective matrix for testing of new catalysts. (Year 2)
3. Demonstrate that the three-dimensional structure of polymer-coated electrocatalyst layers can offset slower kinetics of the catalyst centers when compared with two-dimensional platinum or non-platinum catalysts. (Year 3)
4. Demonstrate that significant stability of the matrix is possible. (Year 3)
5. Demonstrate the design, synthesis and scale up of new catalysts capable of performance that is superior to platinum group metals. (Year 4)

Technical Barriers

This project addresses the following technical barriers from the Fuel Cells section (3.4.4) of the Fuel Cell

Technologies Program Multi-Year Research, Development and Demonstration Plan:

- (C) Performance – more efficient electrodes
- (E) System Thermal and Water Management
- (B) Cost
- (A) Durability

Technical Targets

- Non-Pt catalyst activity per volume of supported catalyst – 300 A/cm³
- Cost <\$3/kW
- Durability >5,000 hours (>120°C)
- Electrochemical area loss <40%
- Electrochemical support loss <30 mV after 100 hrs @ 1.2 V

FY 2011 Accomplishments

- Completed Objective #1 to demonstrate that non-PGM catalysts can be used for oxygen reduction in polymer-coated electrode structures based on polyelectrolyte membranes.
- Completed Objective #2: Non-PGM catalysts have been incorporated into the polymer binders of composite electrodes used in MEAs and have been shown to support high current densities (up to 0.25 A/cm²).
- Developed modeling procedures for prediction of MEA performance using non-PGM catalyst layers. The model has been validated by comparison of predicted performance with experiment. The model predicts that Objective #3) will be achieved and this remains to be confirmed experimentally in the coming year.
- Use of redox mediators within the catalyst layers has been shown to be an effective method to reduce the overpotential of the ORR and to increase electron conduction within the catalyst layers.
- Demonstrated methods for mechanistic determination that provides intrinsic catalyst activity. Combination of these methods with molecular modeling and targeted catalyst synthesis has been initiated to provide well defined pathways to lower overpotentials and higher turnover frequencies (TOF).
- Initiated chemical analysis of catalysts using ion trap mass spectroscopy combined with separation methods to assess catalyst degradation pathways and to allow determination of catalyst turnover numbers (TONs).

Introduction.

Although polymer electrolyte membrane (PEM) fuel cells are relatively efficient energy conversion devices (~50%), there is considerable interest in improving the performance while reducing the cost. An interesting approach is to develop alternative catalysts that are less expensive and also more efficient. Gasteiger and co-workers [1] have provided a very thorough review of the benchmark activities required for Pt, Pt-alloy and non-Pt catalysts for oxygen reduction and which describes in detail different approaches to catalysis of this important reaction. Methods have been reported to prepare non-PGM catalysts that involve a curious procedure whereby a rather complicated molecule such as a metal porphyrin or a complex such as iron phenanthroline is adsorbed on carbon and then heated to over 800°C to form the catalyst [2-5]. In some cases the carbon support is treated with nitrogenous compounds at high temperature followed by addition of metal ions such as Fe or Co. With these non-platinum catalyst structures it is thought that the density of the non-platinum catalytic sites is insufficient to sustain the desired reaction. With the porphyrin catalysts, for example, their poor solubility results in strong adsorption on to the carbon support and insufficient loading of catalyst as well as possible deactivation of the metal center. The pyrolysis process introduces considerable uncertainty as to the actual identity of the catalytic center. Electrode structures are desired which can allow incorporation of catalytic species of known structure into MEAs, which increase the density of the electrocatalysts in the catalyst layer and which allow the homogeneous activity of the catalyst to be retained.

Approach

Homogeneous redox catalysis has been the center of considerable academic attention for several decades and a recent review by Saveant [6] provides an extensive overview of the topic and includes methods of tethering catalysts close to the electrode surface. These methods suggest ways to incorporate into fuel cell MEAs electrocatalysts that mimic very efficient enzyme catalyst centers and may lead to better performance at reduced cost. The principles, advantages and drawbacks behind the approach were explained at greater length in the FY 2010 annual report. The most important advantage of the approach is that the catalyst functions essentially as a homogeneous catalyst that can be thoroughly characterized in solution. This makes design and synthesis of the catalysts more straight forward since they can be studied without resort to surface analysis techniques and to the invocation of surface effects that are poorly understood. Thus, catalysts can be designed from first-principles based on well-known chemistry and physics. The structures of the catalytic centers are understood since the catalysts are synthesized and characterized by classical electrochemical and chemical methods in solution thereby avoiding some of the difficulties that have arisen from surface bound catalysts. The catalysts are then incorporated

into polymers for coating on electrode surfaces and again the behavior can be characterized by simple electrochemical methods prior to incorporation of the polymer-bound catalysts into composite electrodes for MEAs. This last step is critical for the project and represents the Go/No-Go decision point that allows the flow of more efficient catalysts into the PEM fuel cell platform for practical use. This report outlines the progress that has been made in the last year towards fabrication of the MEAs and the development of methods and procedures that will lead to better catalysts and improved electrode structures.

Results

Figure 1 illustrates the process of catalyst screening and measurement of kinetic parameters in solution that facilitates some degree of mechanistic determination for the ORR reaction. Figure 1(a) shows the voltammetric response of a representative manganese porphyrin complex (Mn(III) tetramethylpyridylporphine [TMPyP]) which is soluble in aqueous trifluoromethanesulfonic acid solution due to the quaternized pyridinium groups. The Mn(III)/Mn(II) redox couple is shown to be mostly reversible under nitrogen (solid line) but clearly shows two reductive processes which indicates the presence of different species in solution. The relative heights of the reduction peaks vary with sweep rate, addition of chloride ion and also the pH. This behavior contrasts with that shown by the Fe(III)TMPyP complex under the same conditions which shows a simple reversible wave. The dotted line in Figure 1(a) shows the effect of the presence of oxygen in the solution and the increase in the reduction current can be attributed to the catalytic reduction of oxygen by the Mn(II)TMPyP complex. Again there is an anomalous “cross-over” of the current on the anodic sweep which indicates that the reaction is not completely straightforward, probably due to the presence of different catalyst species in solution. Nevertheless from measurements such as these it is possible to estimate the rate constants of the catalytic reactions [6]. Figure 1(b) shows the results of such measurements for several different metal TMPyP complexes plotted against the redox potential of the complex. These rate constants are derived assuming the mechanism shown in Figure 1(c) which assumes an outer-sphere electron transfer between the reduced metal complex and oxygen to form superoxide ion. The dependence on potential shown in Figure 1(b) is consistent with this mechanism but the absolute values of the rate constants are much too high given the potential difference between the catalyst and the superoxide redox potentials. A more likely mechanistic scenario is shown in Figure 1(d) which shows the formation of an intermediate adduct of the complex with oxygen which in this case is shown as a dimer as this is consistent with some of the behavior reported in the literature for these catalysts. It should be noted that the rate of reaction of the catalyst with oxygen is potential dependent and this dependence is actually contrary to what is desirable for a good catalyst.

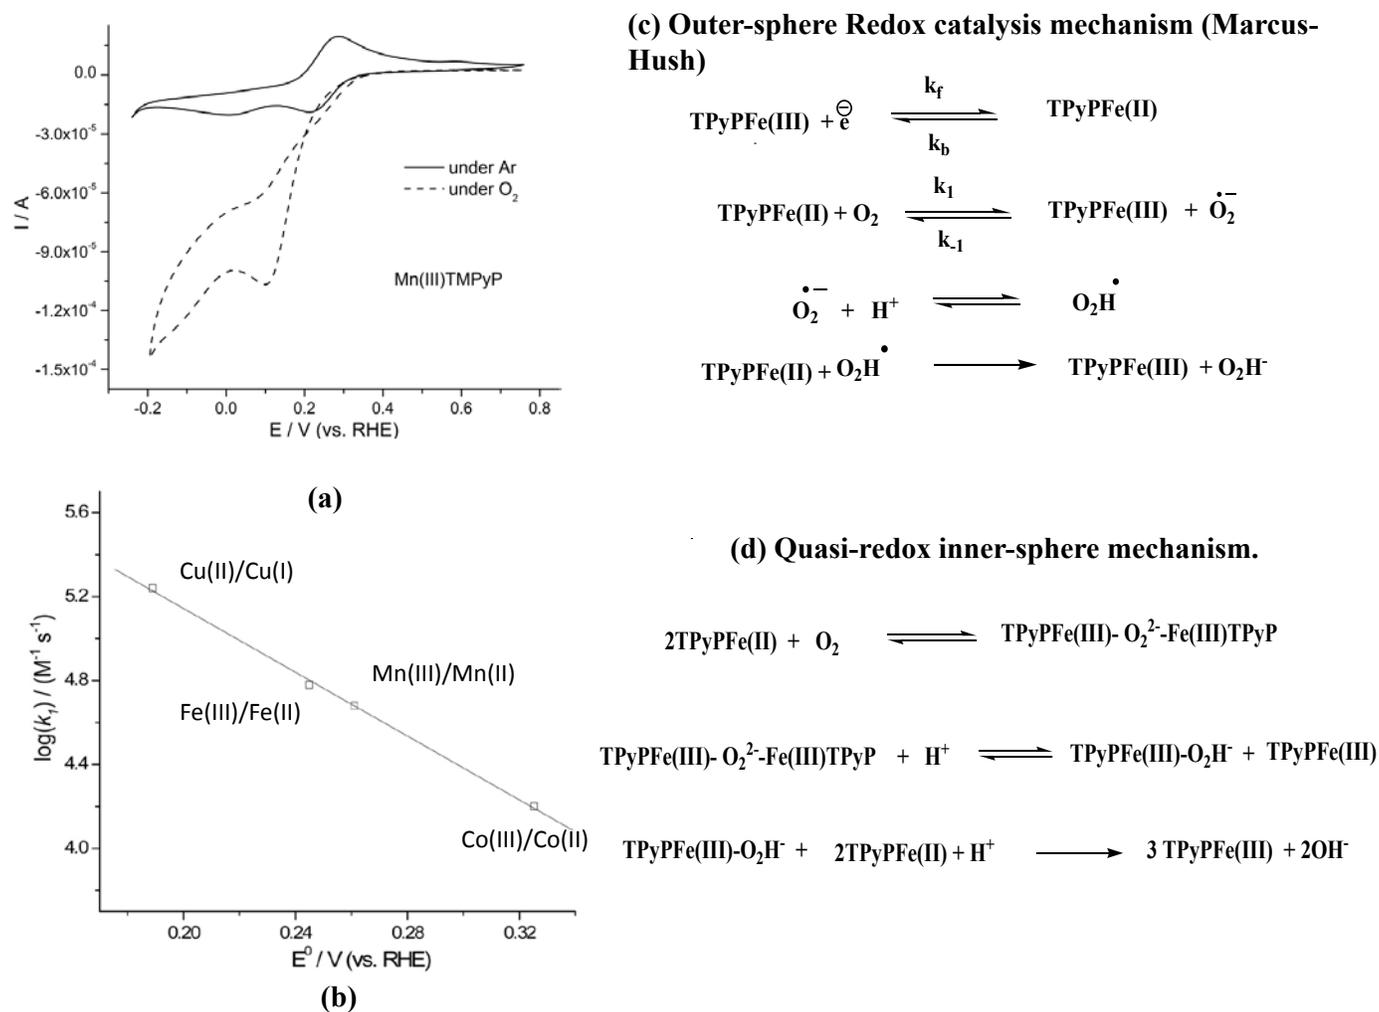

FIGURE 1. Electroanalytical screening and characterization of ORR catalysts; (a) voltammetry of Mn(III)TMPyP (0.8mM) in 0.1M HTFSA/water at glassy carbon under argon and in the presence of oxygen, sweep rate 100 mV/s; (b) plot of rate constants for ORR for different metal TMPyP complexes against the redox potential of the catalysts. Kinetic derivation assumes outer-sphere electron transfer mechanism as shown in 1(c); (c) Outer sphere electron transfer mechanism for ORR; (d) postulated quasi-redox inner-sphere mechanism for ORR.

Figure 2(a) shows the voltammetry of the Fe(III)TMPyP catalyst in trifluoromethanesulfonic acid (HTFSA) under argon, in the presence of O₂ and also in the presence of a soluble ferrocene and oxygen. The ferrocene methanol acts as a redox mediator and catalyzes the reduction of oxygen at lower overpotentials. The mechanism whereby this is thought to occur is shown in Figure 2(b). The electron transfer between the ferrocene and the Fe(III)TMPyP catalyst is driven by the rate of the reaction between the reduced catalyst and O₂. The ferrocene also simply acts as an electron mediator to carry the electrons to the catalyst in a polymer layer as is illustrated in Figure 2(c) which schematically shows the FeTMPyP electrostatically bound to Nafion[®]. Since the catalyst is a 5+ charged cation it is very immobile in the polymer and hence electrons need to be transported to it by some method which the ferrocene fulfills. Figure 2(d) shows how this works in cyclic voltammetry for a Nafion[®]-coated electrode containing the

FeTMPyP catalyst and the ferrocene methanol which is immersed in HTFSA solution. The freshly cast film (blue line) shows strong catalysis of oxygen reduction at the potential that corresponds to the ferrocene methanol. The film was left immersed in the HTFSA solution for two days and the red line shows the resulting behavior for the ORR. The ORR reaction appears to occur at the potential of the FeTMPyP and other non-catalytic couple appears at more positive potentials. This couple appears to correspond to the ester of the ferrocene alcohol which results from reaction with the Nafion[®] and yields a shift of the potential in the positive direction consistent with the electron withdrawing nature of the ester. The lack of catalysis by the ferrocene ester is consistent with the mechanism shown in Figure 2(b) as the potential difference between the redox potentials of Fe(III)TMPyP and the ferrocene ester is too large for the rate of the oxygen reaction to overcome. Catalysis over this potential range would be possible if the rate of reaction with

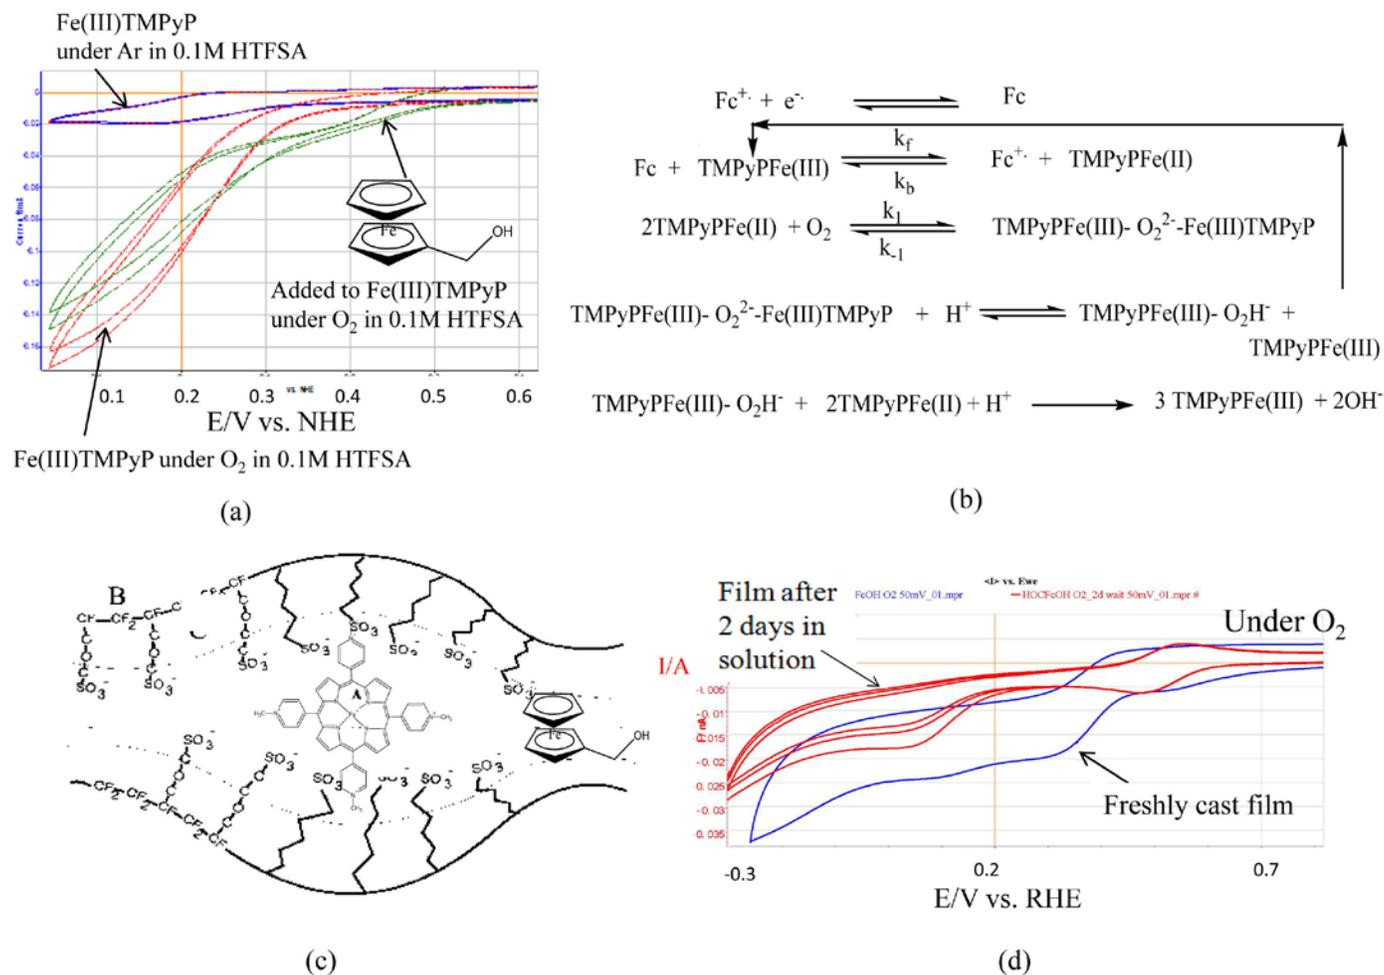

FIGURE 2. (a) Voltammetry of Fe(III)TMPyP in aqueous 0.1M HTFSA at glassy carbon, sweep rate 50 mV/s showing response under argon, in the presence of oxygen and in the presence of oxygen with added ferrocene methanol; (b) mechanism for ORR with addition of ferrocenemethanol to account for ORR at more positive potentials as shown in Figure 1(a); (c) schematic of Fe(III)TMPyP bound to Nafion® polymer layers which also contain ferrocene methanol as an electron mediator; (d) voltammetric response of freshly cast Nafion® film on a glassy carbon electrode containing Fe(III)TMPyP and ferrocene methanol in aqueous 0.1M HTFSA solution saturated with O₂. Blue curve is freshly cast film, red curve is after two days in 0.1M HTFSA solution.

O₂ was much larger, say two orders of magnitude higher. It is important to note also that both catalyst and mediator appear to remain bound in the polymer layer over an extended period which indicates they do not wash out.

The process of transferring these catalysts into the catalyst layer of an MEA is shown in Figure 3. Figure 3(a) shows the catalyst layer consisting of a number of carbon support particles which are coated with the polymer layer containing the catalyst and mediator. The carbon particles connect electronically to the current collector gas diffusion layer. Figure 3(b) shows the dynamics of the charge and mass transport through the polymer layers that have to be accounted for and Figure 3(c) shows the flow of electrons in simplified form. A number of literature measurements for the transport properties of the electrons, protons, oxygen and water have been used to try to predict the behavior of the electrode in an MEA and the results of the

modeling are shown in Figure 3(d) which are compared with experimental results from the polarization curves of MEAs prepared with catalyst layers containing the Fe(III)TMPyP and ferrocene methanol. The model also makes assumptions regarding the overpotential and the catalytic activity of the catalyst. It can be seen that there is surprisingly close agreement for these early results and the model. Figure 3(e) shows the effect of variation of the formulation of the electrode ink where the catalyst concentration is reduced but the mediator concentration remains the same. However, as a result the concentration of proton carriers also decreases. The MEA performance reflects the lower density of the catalysts as well as the increase in resistance due to fewer proton carriers.

Figure 4(a) shows the best MEA performance to date obtained with the Co(III)TMPyP catalyst, ferrocene methanol mediator and different surface area carbons

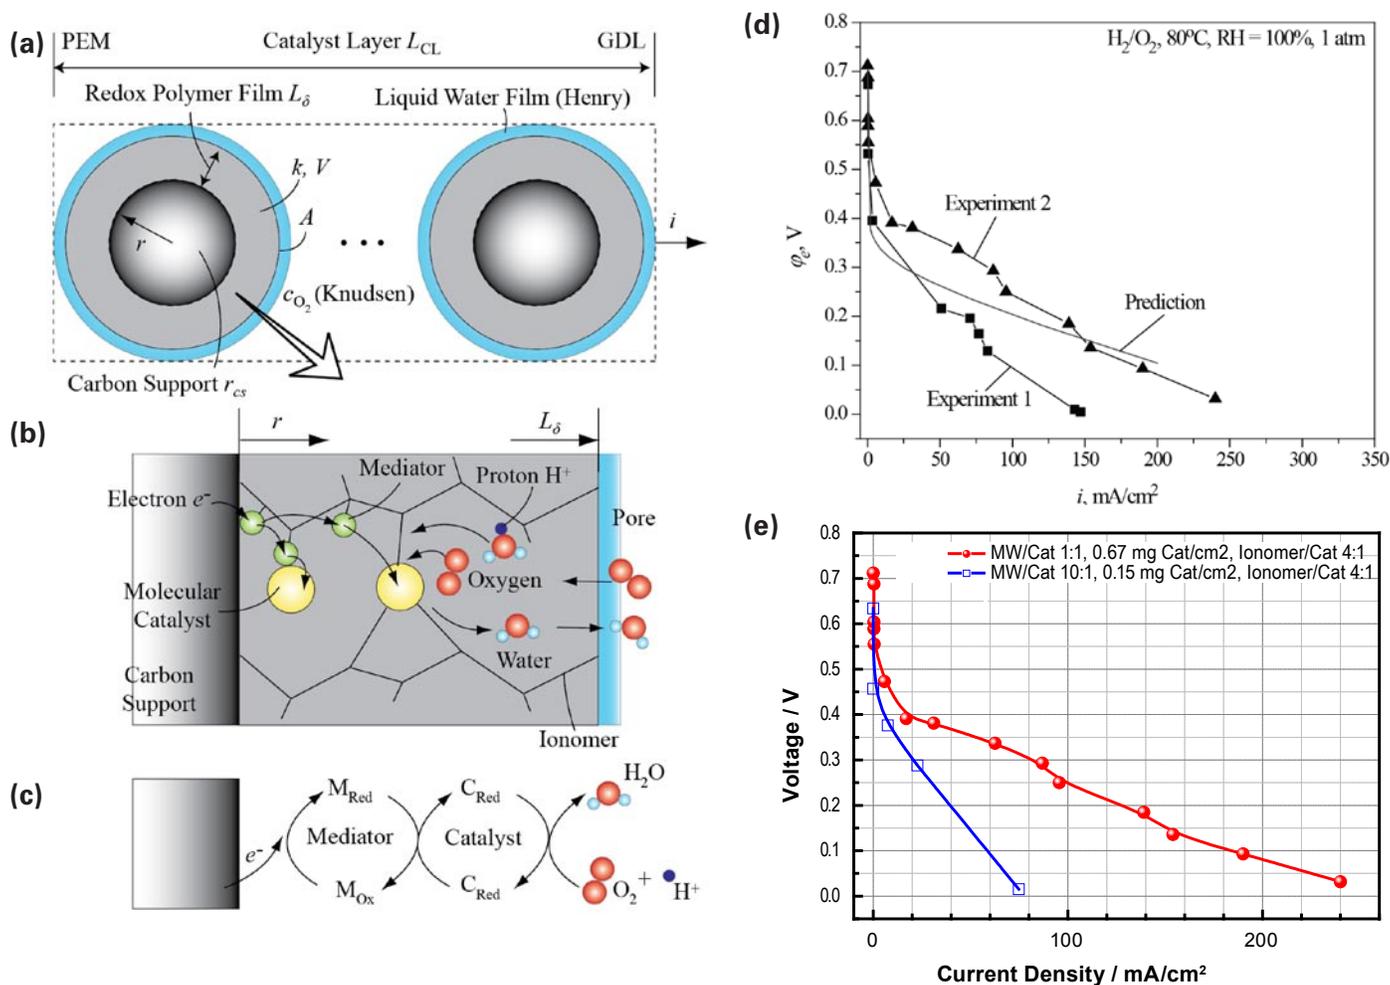

FIGURE 3. Model and experimental results of MEA electrodes containing three-dimensional arrays of Fe(III)TMPyP catalysts and ferrocene methanol mediators; (a) schematic of catalyst layer structure; (b) schematic of polymer film structure and dynamics of transport; (c) simplified diagram of electron transport within the catalyst layer; (d) model prediction compared with experimental results for MEA with Fe(III)TMPyP catalyst and ferrocene methanol mediator; (e) MEA results for lower catalyst density, higher mediator density and lower proton carrier density in catalyst layer.

current collectors. Comparison with control experiments with uncatalyzed carbons show an order of magnitude higher current densities and open-circuit voltage values that are 300 mV higher. It is clear that the concept of the polymer-supported homogenous catalyst actually works and the current densities achieved here correspond to TOF numbers of about 10 per second for the catalysts. The actual loading of catalyst sites estimated for these MEAs is about 100 times less than those reported for pyrrolized MEA systems [7]. However, comparison with commercial platinum electrodes (shown in the inset) demonstrates a long way to go, particularly with respect to voltage. Similar current densities as Pt/C TOF values of around 50/s are required or a higher density of catalyst in the catalyst layer. To achieve a lower overpotential and hence higher cell voltage not only are higher rate catalysts required but catalysts with more positive redox potentials are required.

Figure 4(b) illustrates an approach that involves molecular modeling to determine the structural features that control the catalyst redox potential (nature of the metal center, substituents on the ligands) as well as the rate of reaction with the oxygen. Figure 4(b) shows a model of the Fe(II) TMPyP with a fifth ligand (imidazole) bound to the metal and the oxygen occupying the sixth position. Modeling shows some deformation of the ring geometry occurs. It has also been shown that replacement of the quaternary methyls on the pyridines with protons results in slower reaction with O_2 . These results demonstrate the need for a systematic program of modeling, guided synthesis and electrochemical screening to lead the program towards better catalysts. A more empirical approach is shown in Figure 4(c) which shows the electropolymerization of dipyrromethanes which when combined with cobalt ions gives a polymer catalyst layer with interesting catalytic properties as shown in

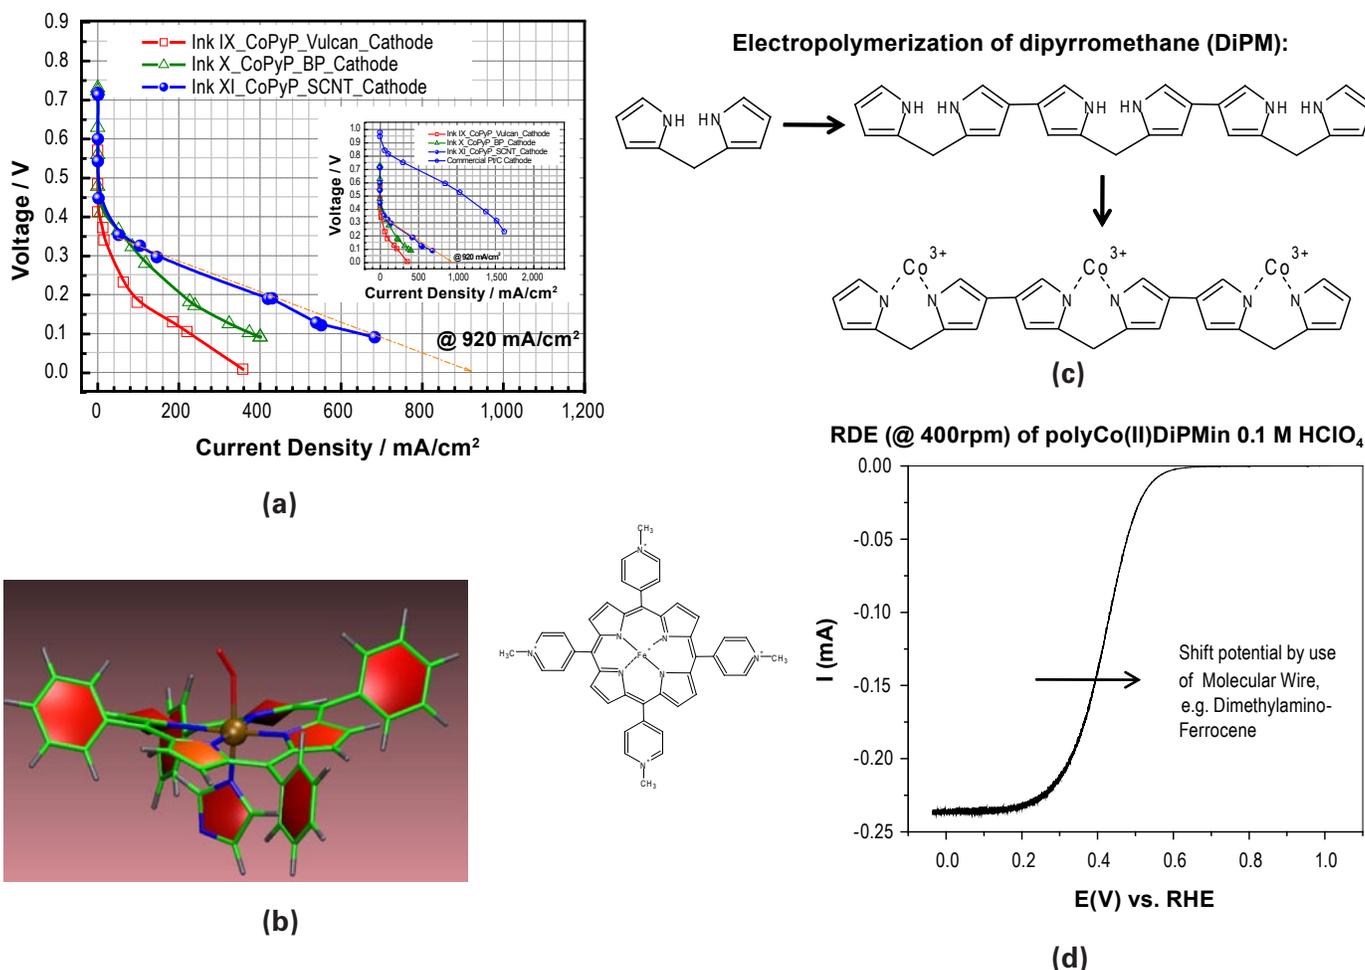

FIGURE 4. (a) Comparison of MEA results from Figure 3(a) with blank carbon with no added catalyst (control). Inset shows comparison with commercial Pt/C electrode under similar conditions; (b) computational model of FeTMPyP complex with imidazole bound as a fifth ligand and O_2 bound to the sixth position; electropolymerization of dipyrromethane and Co^{3+} to form an ORR polymer-catalyst layer; (d) Voltammetric response of catalyst layer formed in 4(c) in the presence of O_2 .

Figure 4(d). This approach takes advantage of previously successful combination of catalysts with conducting polymers [7]. Combination with redox mediators and proper construction of catalyst layer structures as illustrated in Figure 3 hold the potential to greatly improve the operating potential of the MEA.

Conclusions and Future Directions

Conclusions

- The results from the MEA experiments reported here represent a proof-of-principle of the concept of polymer-supported three-dimensional catalyst arrays for MEA. The correspondence of the modeling with the experimental results indicates that the correct parameters are being considered.

- The correspondence of the MEA results with the electroanalytical results indicates that a practical method catalyst screening exists that is rapid, inexpensive and relevant to MEA operation. Quantitative electroanalytical results are applicable to MEA operation through the electrode modeling.
- Better catalysts can be obtained through fundamental understanding of the factors that influence redox potential and rate of reaction with oxygen. Molecular modeling can address these problems.

Future Directions

- Optimization of MEA fabrication to improve performance.
- Use of electrochemical techniques including impedance to determine rate limiting phenomena in the MEAs and

correlation with electroanalytical measurements made using conventional cell systems.

- Development of a coordinated molecular modeling/ synthesis/electrochemical screening process that will provide understanding of the catalyst structural features that yield better performance.

catalysts based on tungsten oxide and/or heteropolyacid/C supported Pt.

Technical Barriers

This project addresses the following technical barriers from the Fuel Cells section (3.4.4) of the Fuel Cell Technologies Program Multi-Year Research, Development and Demonstration Plan:

- (A) Durability (of catalysts and membrane electrode assemblies)
- (B) Cost (of catalysts and membrane electrode assemblies)
- (C) Performance (of catalysts and membrane electrode assemblies)
- (D) Start-up and Shut-down Time and Energy/Transient Operation (Support Corrosion)

Technical Targets

This project synthesizes novel Pt-based electrocatalysts on alternative oxide supports. The project has targets outlined in the Multi-Year Research, Development and Demonstration Plan for both electrocatalysts for transportation applications (Table 3.4.12) and MEAs (Table 3.4.13). An enhancement in electrocatalytic activity by a factor of 4x (from the benchmark Pt/C metrics) and the ability to withstand 30,000 start-up/shut-down cycles and open circuit voltage holds with an electrochemically available surface area (ECA) loss of <30% are included.

Background

One of the critical goals to achieve the automotive commercialization targets is improved durability. Although durability of the fuel cell system has been improved, some of the improvements come with increased system complexity and cost. This project addresses the issue of catalyst support degradation during normal operation and especially under start-stop conditions when the fuel cell cathode experiences high transient potentials approaching 1.6 V. Typical carbon blacks used today corrode easily under these conditions and complex systems operations are being employed to mitigate it at this time. We propose to use corrosion-resistant oxide supports as a solution. In addition to corrosion resistance, this project will attempt to strengthen the support-Pt anchoring and also lower the total Pt loading in the cathode of the catalyst layer.

Fiscal Year (FY) 2011 Objectives

To help DOE address critical shortcomings in catalyst performance and durability by synthesizing novel

FY 2011 Accomplishments

- Prepared different stoichiometries of nano-WO₃ for Pt deposition by atomic layer deposition (ALD) and characterized the material using X-ray diffraction and Brunauer-Emmett-Teller. Demonstrated and characterized improved structure Pt/WO₃.
- Evaluated Pt catalyzed support corrosion as a baseline for stability of Pt/WO₃. Evaluated Pt/WO₃ in electrochemical half-cells for ECA and oxygen reduction reaction (ORR) activity. Investigated several alternative methods for the measurement of ECA accurately.
- Completed following milestones:
 - 5.7.0 Demonstrate nano-structured Pt on WO₃, heteropoly acid (HPA), or a combination of the two. (100% completed) 09/2010.
 - 5.7.1 Demonstrate controlled nano-structured Pt placement and loading on WO₃, HPA, or a combination of the two. (100% completed) 12/2010.

- 5.7.2 Obtain cyclic voltammograms (CVs) and mass activity for Pt on WO₃, HPA, or a combination of the two. (100% completed) 2/28/11
- 5.7.3 Prepare high surface area catalyst electrodes based on tungsten oxide and tungsten-based heteropoly acids (HPAs), test electrochemically in half-cells, and compare to the corrosion of typical carbon blacks for proton exchange membrane fuel cells (PEMFCs) up to 1.5 V. (100% completed) 4/2011
- 5.7.4 Obtain CVs and mass activity for Pt on WO₃, HPA or a combination of the two with ECAs greater than 10 m²/g Pt. (100% completed) 9/2011.

Introduction

Before polymer electrode membrane fuel cells (PEMFCs) can be fully commercialized, improvements in cost and durability must be achieved [1]. Key to the PEMFC operation is the catalysis of the ORR on the cathode. An ideal ORR catalyst efficiently converts O₂, protons, and electrons to water, produces no peroxide byproducts, and is inexpensive and durable. The sluggish kinetics of the ORR on Pt-based electrocatalysts used today requires a high loading of Pt-based catalyst on the cathode with consequent concurrent increased costs. PEMFC cathode catalysts are supported on high surface area carbon blacks that are known to be thermodynamically unstable in the entire fuel cell operating regime. The kinetics of carbon corrosion are slow below 1 V, but catastrophic losses are observed when the cathode sees transient fluctuations in the 1-1.6 V regime (during start-up shut-down phenomena). Under these conditions, Pt nanoparticles are susceptible to agglomeration. Clearly there is a need for an improved corrosion-resistant support that strongly anchors the Pt strongly to the support and synergistically enhances the catalyst system ORR activity [2,3].

Approach

Our approach is multi-pronged and addresses the catalyst, support, catalyst/support interaction and functionalization of the support. Examination of Pourbaix diagrams reveals that the metals that are fairly stable in acid conditions at the potentials of interest are Ir, Pt and Au, and candidate metal oxides that are thermodynamically stable include Ti, Zr, Nb, Ta and W [2,3]. Various stoichiometries and crystallinities of WO_x nanorods are being grown using hot wire deposition (HWD); wet chemistry is also being pursued to produce different nanostructures of WO_x. These supports are projected to provide the desired higher corrosion resistance at these high transient potentials. Pt nanoparticles are being deposited on WO_x using ALD and wet-chemical methods. Heteropoly acid (HPA) materials being synthesized and characterized at CSM are candidates

for co-catalysts because they can be readily synthesized and assembled into nano-ordered ensembles on many electrode materials. The most promising HPA structures are being attached to the WO_x nanoparticles and carbon blacks. Part of the approach is to combine a high surface area carbon electrode with a tungsten oxide and/or HPA that can enable enhanced activity of Pt for the ORR and enhanced stability of the Pt catalyst particles [4,5]. The challenge is to develop i) electrode support materials that are resistant to corrosion in the entire PEMFC operating environment, ii) electrode support materials that strongly anchor the Pt nanoparticles to prevent agglomeration, iii) electrode support and functionalized materials that have sufficient conductivity to provide both electronic and protonic conduction paths, iv) catalyst-support systems that lower peroxide generation, and v) electrode structures that have the optimal electrode structure/porosity/hydrophobicity/hydrophilicity to minimize mass-transport losses. Overall, our approach is to develop a catalyst system that approaches the DOE activity, performance and cost benchmarks.

Results

Commercial Pt/C electrocatalysts were evaluated by rotating disk electrodes (RDEs) and characterized for ECA, specific and mass activity [6-8]. These catalysts were found to meet and even exceed literature benchmarks (Figure 1) validating our measurement and preparation methods. Baseline and newly synthesized materials were also screened for corrosion resistance in electrochemical half-cells. Because standardized protocols for evaluating Pt/alternative supports do not exist, a durability working group sub-team lead by NREL that includes members from Los Alamos National Laboratory, NTCNA and Illinois Institute of Technology are working jointly to develop these protocols. The protocols under development involve potential cycling in the typical automotive regime of 0.6–1.0 V as well as in the start-up/shut-down regime of 1.0–1.6 V. Furthermore, in preparation for testing of selected Pt/alternative support candidates as fuel cell electrodes, baseline Pt/C catalysts were evaluated in subscale fuel cells at NREL and demonstrated to meet and even exceed the DOE benchmarks of ORR electrocatalytic activity (Table 1).

WO_x support materials were prepared by HWD as well as wet chemistry, as shown in Figures 2 and 3 respectively. Pt was deposited onto WO_x supports using ALD but was initially found to have a non-uniform distribution. Using TiO₂ as a proxy support allowed us to monitor in situ the loading of Pt as a function of number of ALD cycles. We were then able to optimize the process and significantly improve Pt nanoparticles dispersed on WO_x (Figure 4). The materials were screened for morphology, surface area, and electrochemical stability by excursions to high potentials. We found them to possess superior stability as compared to carbon blacks. These studies confirmed that WO_x supports are more stable than carbon blacks and Pt/WO_x is more stable than Pt/C (Figure 5).

for ECA and activity. Two issues arise with electrochemical measurements: In measuring CVs, we find that the WO_x contributes charge to the hydrogen underpotential deposition (UPD) region due to formation of tungstates (Figure 6). This issue can be bypassed by using Cu UPD or CO chemisorption to measure the ECA and has been performed (Figure 7). ECA values are in the range of 10–14 m²/g. In measuring ORR current-voltage curves, high stoic WO₃ with lower electronic conductivity resulted in lower activity; the impact could be partially mitigated by mixing small amounts of carbon black to the ink formulation (Figure 8). At this time, the highest specific activity measured is comparable to that of conventional Pt/C while the mass activity is lower due to the lower surface area.

Commercial Pt/C (2.5 nm Pt nanoparticles on high surface area carbon) was functionalized with HPA by CSM

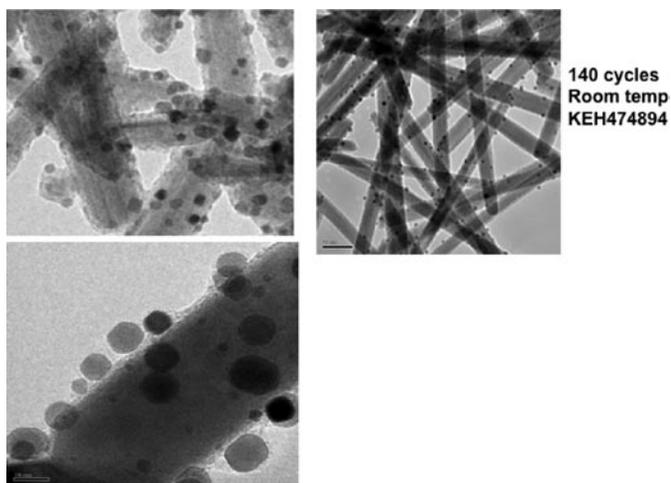

FIGURE 4. TEM Micrographs of Pt/WO_x Grown Using ALD

and the resultant materials tested in RDE for activity and durability. Interesting peaks were found related to the functionalization but no improvement or degradation of ORR activity was observed.

Conclusions and Future Direction

Platinum on WO_x was deposited using ALD producing particle sizes and distribution with good

control, albeit with a low surface area of about $10 \text{ m}^2/\text{g}$. Electrochemical measurements were conducted to resolve issues of (1) measurement of ECA, (2) the impact of lower electronic conductivity of WO_x on the ORR activity, and (3) significantly improved support corrosion compared to conventional carbon blacks. Future work involves, lowering the particle size thus increasing the ECA and achieving the mass activity of baseline Pt/C while simultaneously demonstrating higher durability using newly developed protocols. The next steps can be outlined as follows:

Tungsten Oxide: Improve the characterization of metal oxide substrate: produce increased quantities.

Pt Deposition: Use ALD and wet-chemistry techniques to deposit smaller and a more uniform distribution of nanoparticles of Pt on the oxide support to increase the ECA.

HPA: Functionalize plain carbon blacks and deposit Pt in a controlled manner on the resultant material. Once the platinum hybrid HPA carbon has been developed CSM will investigate how it can be used to control the morphology of Pt nanoparticles from either Pt black, chemical reduction or electrochemical reduction.

Electrode Studies: Resolve the ECA measurement issues due to contributions from WO_x to the hydrogen UPD. Evaluate the effect of addition of carbon black to the catalyst to enhance electronic conductivity and ORR performance. Develop appropriate protocols for

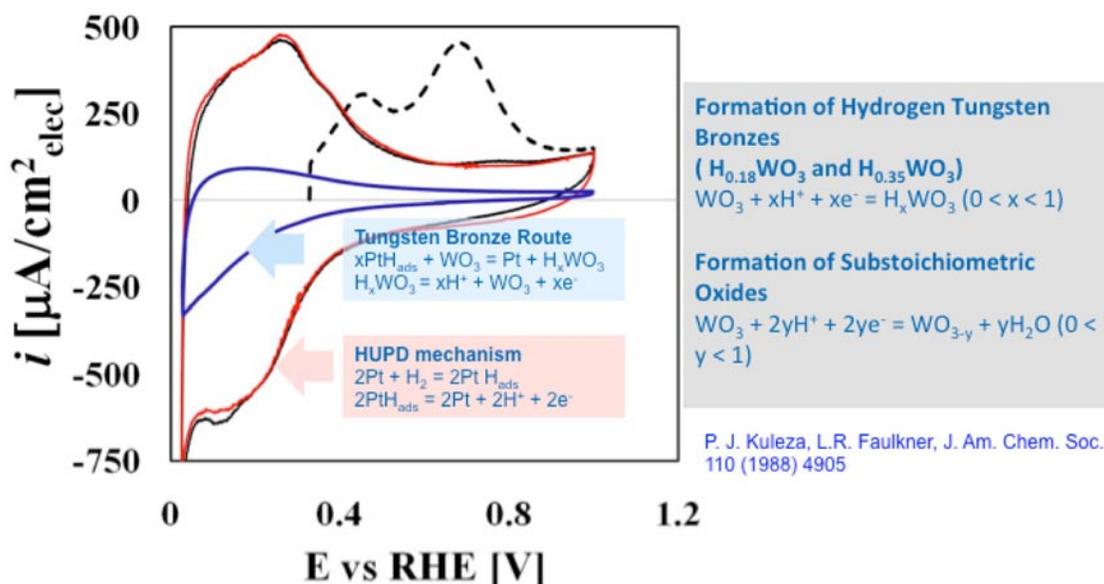

FIGURE 6. CVs showing the impact of contribution from WO_x in the HUPD region. Cu UPD might give a better estimate of ECA since hydrogen UPD region includes charge due to formation of H_xWO_3 as well as spill over effects.

the evaluation of alternative catalyst support durability. Demonstrate electrochemical (RDE) durability of Pt/WO_x as a function of the initial ECA using the developed protocols. Achieve specific and mass activity for $\text{Pt}/\text{WO}_x/\text{HPA}$ that is comparable to and eventually higher than conventional Pt/C .

- <30 mV electrocatalyst support loss in the synthesized supports after 100 hrs at 1.2 mV; tested per GM protocol.

At the time of writing, the first set of samples prepared have undergone durability testing.

FY 2011 Accomplishments

- Demonstrated that the synthesized RuO₂-SiO₂ catalyst supports possess the following properties: a) high Brunauer-Emmett-Teller (BET) surface areas (260 m²/g), b) excellent electrical conductivity (up to 24 S/cm), and c) improved electrochemical stability. Start-stop stability tests were performed by cycling electrode potential between 0 V to 1.8 V for 1,000 cycles. The results showed no loss in surface area for the RuO₂-SiO₂ catalyst supports, while a 44% drop in surface area was observed in carbon supports tested as a baseline.
- Synthesized functionalized silica supports with several levels of sulfonic acid functionalization. These materials have demonstrated varying degrees of proton conductivity and electrochemical stability.
- Demonstrated fuel cell performance with a platinum catalyst supported on non-carbon catalyst supports synthesized in this study – Pt/RuO₂-SiO₂.

Fiscal Year (FY) 2011 Objectives

- To develop and optimize innovative non-carbon mixed conducting materials that will serve as corrosion resistant, high surface area supports for anode and cathode electrocatalysts; and
- Concomitantly facilitate the lowering of ionomer loading in the electrode (by virtue of surface proton conductivity of the electrocatalyst support), thereby enhancing performance.

Technical Barriers

This project addresses the following technical barriers from the Fuel Cells section of the Fuel Cell Technologies Program Multi-Year Research, Development and Demonstration Plan:

(A) Durability

Technical Targets

This project addresses the following technical targets:

- <40% electrochemical surface area (ECSA) loss in electrocatalysts using the synthesized supports tested per General Motors (GM) protocol.

Introduction

While Pt supported on carbon is the most commonly used electrocatalyst for polymer electrolyte fuel cells (PEFCs), the carbon support has limitations with respect to its durability at high temperatures and the excursions to high electrode potentials that arise during start-up and shut-down sequences and during fuel starvation. The issue of carbon-carbon corrosion is a major technical barrier. Carbon corrosion facilitates the agglomeration of Pt particles and dissolution of Pt from the support, which leads to a loss in the ECSA of the electrode [1]. To address this issue, the development of non-carbon mixed-conducting catalyst support materials is explored. Desirable properties of these alternative materials include: (i) high surface area; (ii) high electrical conductivity; and (iii) high electrochemical stability. In addition, it is hypothesized that fuel cell performance can be enhanced by utilizing non-carbon catalyst supports that conduct protons on their surface. The addition of sulfonic acid functionalities on the support surface should permit lowering the ionomer content in the electrode, thereby enhancing gas transport to the catalyst site without compromising on the efficacy of ion transport.

Approach

To achieve the first of two objectives discussed above, two approaches have been employed. The first approach involves the development of a core-shell-like RuO_2 - SiO_2 structure that serves as the catalyst support. High surface area silica functionalized with sulfonic acid groups (HSO_3^-) was used as core matrix. This matrix was further functionalized with a shell layer of RuO_2 to introduce electronic conductivity; the final material was calcined at temperatures ranging from 100–450°C. The electrochemical stability of RuO_2 - SiO_2 , Pt/RuO_2 - SiO_2 , and HSO_3^- - SiO_2 were measured and compared with that of commercial Pt/C and XC-72R carbon. The electrical and proton conductivities and BET surface areas of materials prepared with different extents of functionalization were also measured.

The second approach involved the synthesis of sulfonic acid functionalized silica with a bimodal pore-structure. The intent of this approach was for RuO_2 to be selectively impregnated in the mesopores of the bimodal structure, while leaving the macropores free for reactant and product transport.

Results

BET Surface Area and Electrical Conductivity

A series of core-shell-like structures of RuO_2 - SiO_2 have been synthesized and characterized in terms of electrochemical stability, electrical conductivity, and BET surface area values. The BET surface areas of supports with 0, 9, 33, 50, and 60 mol% of RuO_2 were measured to be 1,100, 470, 420, 260 and 220 m^2/g , respectively. These values show considerable improvement over the values obtained with the co-condensation approach reported in our earlier work [2]. The electrical conductivity of the supports was estimated using a 2-point probe by linear-sweep voltammetry. As shown in Figure 1a, the electronic conductivity was significantly higher for the support materials calcined at 450°C than for those calcined at 100°C. X-ray diffraction (XRD) analysis confirmed that the difference was due to the extent of crystallinity of the material that was enhanced while annealing at higher temperatures. Additionally, the increase in conductivity with RuO_2 loading is very sharp up to a loading of 40%, following which the rate of increase of conductivity is less rapid. This difference in the rate of increase of conductivity with loading is attributed to the amount of RuO_2 particles needed for creating optimal pathways (i.e. percolated network) to conduct electrons. Above 40 mol% of RuO_2 , there is a sufficient amount of RuO_2 particles available for electron conductivity. The electrical conductivity of the sample with 33 mol% RuO_2 loading is 3 S/cm, a value that is adequate for fuel cell operation. These results suggest that RuO_2 - SiO_2 is indeed a viable high surface area catalyst support with adequate electrical conductivity. Given that the BET surface area is drastically lowered as the amount of RuO_2 in the sample is increased,

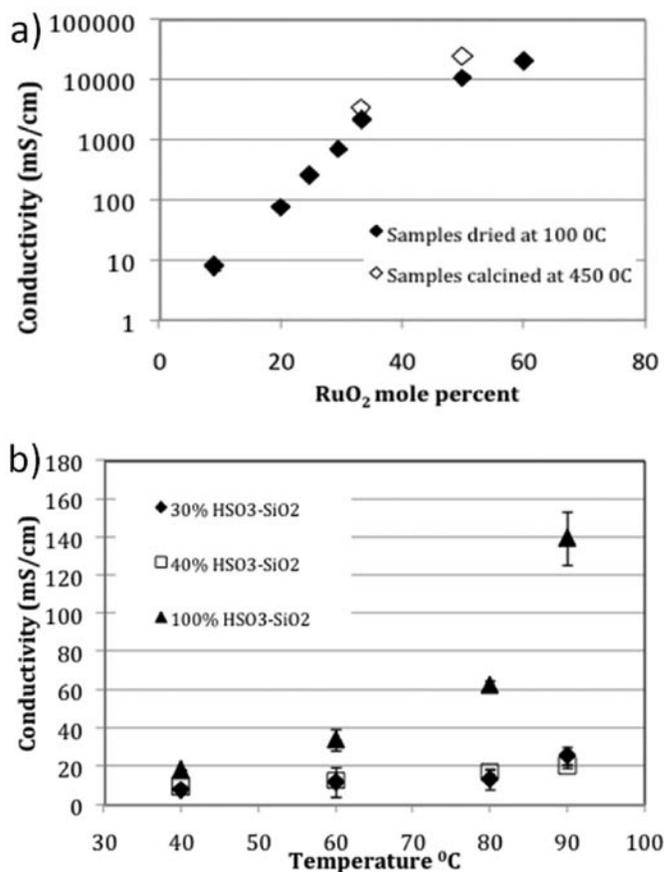

FIGURE 1. (a). Electrical conductivity of RuO_2 functionalized silica. All measurements were obtained at room temperature. (b). Proton conductivity of sulfonic acid functionalized silica at various temperatures. All measurements were obtained at 100% relative humidity (RH).

future research will focus on lowering the RuO_2 content while maintaining or enhancing the electrical conductivity by tuning the distribution of RuO_2 in the silica matrix. To accomplish this task, work has been initiated on the second approach stated above, namely the synthesis of silica with a bimodal pore-structure, wherein the ruthenium oxide can be selectively impregnated in the mesopores, leaving the macropores free for reactant and product transport.

Stability of Catalyst Supports

The stability of the different RuO_2 functionalized silica supports was evaluated by potential cycling using a rotating disk electrode (RDE) setup. The support samples were coated on a glassy carbon (GC) disk electrode and the cycling experiment was carried out in a N_2 saturated 0.1M HClO_4 solution. The catalyst support loading was controlled at 200 $\mu\text{g}/\text{cm}^2$ for all experiments. The supports were cycled between 0 to 1.8 V vs. reference hydrogen electrode (RHE) at a scan rate of 1 V/s for up to 1,000 cycles, and cyclic voltammograms (CVs) were recorded at periodic intervals at a scan rate of 10 mV/s. The CVs recorded were analyzed

to assess the double-layer charge (Q_{DL}) of the supports. This metric was employed as a preliminary estimate of support surface area and stability. The stability data obtained using the RuO_2-SiO_2 , HSO_3-SiO_2 and XC-72R carbon samples upon potential cycling are shown in Figure 2. Both RuO_2-SiO_2 supports exhibited excellent stability in contrast to carbon, while still showing Q_{DL} values similar to that of carbon. Carbon showed a 44% drop in Q_{DL} after 1,000 cycles due to loss in surface area, while the RuO_2-SiO_2 supports did not show any loss in Q_{DL} . HSO_3-SiO_2 did not show a change in Q_{DL} during potential cycling, but it had a much lower Q_{DL} compared to carbon. The samples tested here have been shipped to NTCNA for further stability evaluation using prescribed protocols. These tests are underway.

Ion Exchange Capacity (IEC)

The IEC of the silica supports functionalized with varying amounts of sulfonic acid groups was measured by titration. The surface area of the functionalized silica was determined by the BET method. The presence of HSO_3 in these samples was confirmed by IEC measurements, which revealed that the samples had an IEC ranging from 1.7-2.1 meq/g. The IEC did not change substantially with extent of functionalization, but was much higher than the near-zero IEC obtained for unfunctionalized silica samples. The BET surface areas of the 20%, 30%, and 40% functionalized HSO_3-SiO_2 samples were 650, 520, and 450 m^2/g , respectively. The BET surface area decreased as the extent of functionalization was increased; however, the values obtained are in excess of requirements even at high levels of functionalization.

Proton Conductivity

Preliminary proton conductivity measurements were performed at 40, 60, 80 and 90°C at 100% RH for samples

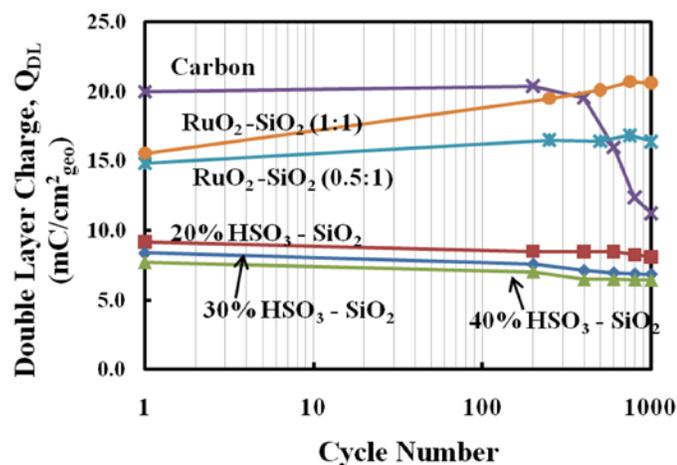

FIGURE 2. Double layer charge obtained from synthesized RuO_2-SiO_2 , sulfonic acid functionalized silica, and Vulcan XC-72R carbon during potential cycling between 0 to 1.8 V vs. RHE.

with 30, 40 and 100% extents of functionalization (data shown in Figure 1b). Proton conductivity measurements were performed with a two-point conductivity cell using electrochemical impedance spectroscopy. A maximum proton conductivity of 140 mS/cm was obtained for 100% HSO_3-SiO_2 , while 30 and 40% HSO_3-SiO_2 had much lower proton conductivities in the range of 7-25 mS/cm. In line with expectations, high levels of functionalization of SiO_2 allowed for more efficient proton conduction. However, the 100% functionalized HSO_3-SiO_2 was not thermally stable and decomposed around 100°C. One approach to solve this issue that is currently being pursued is to employ and functionalize templates with greater thermal stability, such as polyhedral oligomeric silsesquioxanes.

Stability of Catalyst

Platinum was deposited on selected non-carbon supports using conventional deposition methods. The stability of the Pt on RuO_2-SiO_2 supports was again characterized by potential cycling using a RDE. The catalyst loading on the GC disk was controlled to 50 $\mu g/cm^2$ of Pt and 200 $\mu g/cm^2$ of RuO_2-SiO_2 support for all stability experiments. The supports were cycled between 0 to 1.2 V vs. RHE at a scan rate of 1 V/s for up to 10,000 cycles, and CVs were recorded at intermediate points (at 10 mV/s) to determine the ECSA of the Pt.

ECSA was calculated from the difference between the total charge involved in the hydrogen desorption and the double-layer charge using the specific H_{upd} charge of 210 $\mu C/cm^2$. The ECSA values for 20% Pt deposited on RuO_2-SiO_2 and 57% Pt/C are shown in Figure 3. The 20% Pt/ RuO_2-SiO_2 exhibited consistently high ECSA ($>100 m^2/g_{Pt}$) and showed high stability for up to 10,000 cycles. The 57% Pt/C showed deterioration of ECSA under this potential cycling test.

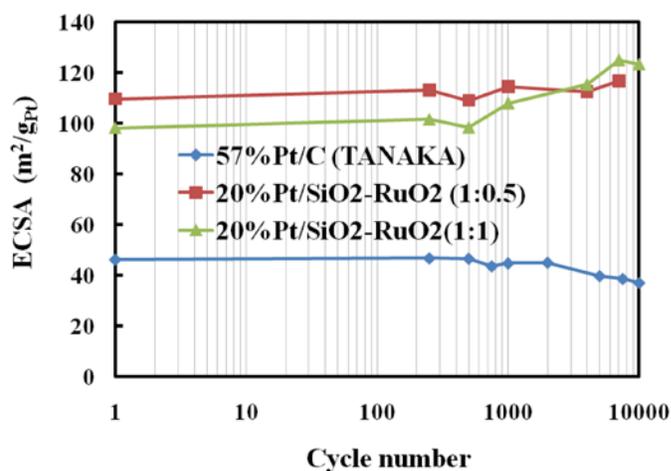

FIGURE 3. ECSA of Pt supported on RuO_2-SiO_2 and Pt/C (57%, TTK) after 10,000 potential cycles between 0 to 1.2 V vs. RHE.

Ex situ benchmarking of various Pt-based catalysts with different carbon supports has been completed at NTCNA. Start-stop cycling and load cycling durability tests have been performed by cycling electrode potential between 1.0 V to 1.5 V (triangular wave form) and between 0.6 V to 1.0 V (rectangular wave form). The results of these tests show that NTCNA has acquired a very good understanding of the interplay between Pt and its support on durability of the catalyst. NTCNA is also performing ex situ benchmarking of various un-catalyzed carbon supports for their durability using the start-stop cycling protocol. These tests are expected to provide a more in-depth understanding of the support material's stability, which will help benchmarking the non-carbon supports being developed under this project. Finally, NTCNA is currently working to evaluate the durability of non-carbon supports developed at IIT using the above protocols. The results obtained at NTCNA will be further described in the forthcoming quarterly report.

Fuel Cell Performance

Preliminary fuel cell performance has been demonstrated with the non-carbon support catalyst. Figure 4 shows the polarization curves of a PEFC employing Pt/RuO₂-SiO₂ at the anode and cathode. The current density at 0.6 V was 750 mA/cm², and the maximum power density obtained was 570 mW/cm² under H₂/O₂. Further analysis of polarization data is in progress.

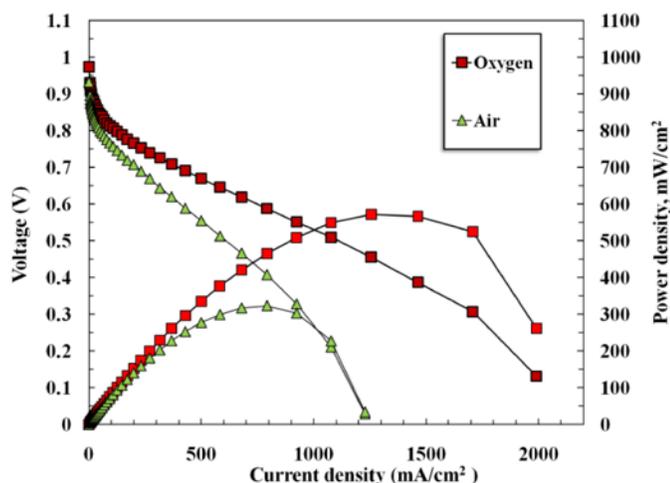

FIGURE 4. Polarization curves obtained from a PEFC membrane electrode assembly prepared using Pt/RuO₂-SiO₂ electrocatalysts at both electrodes. Measurements were conducted at 80°C with 75% RH. Reactant flow rates were set at two times the stoichiometric requirement for both H₂ and O₂/air. Pt loading was controlled at 0.4 mg/cm² at the cathode and 0.2 mg/cm² at the anode.

Conclusions and Future Directions

- Highly durable RuO₂-SiO₂ catalyst supports with a core-shell-like structure were synthesized with high BET surface areas and electron conductivities.
- Both RuO₂-SiO₂ and Pt/RuO₂-SiO₂ materials exhibited superior electrochemical stability in comparison to carbon catalyst supports under potential cycling tests.
- Several samples of sulfonic acid functionalized silica have been prepared, and they demonstrate excellent proton conductivity.
- Promising preliminary fuel cell performance with H₂/O₂ has been obtained with Pt/ RuO₂-SiO₂ electrodes.
- Future efforts will be focused on refining microstructure-property relationships in the ruthenium oxide-silica composite system in terms of extent of functionalization, pore-structure of silica/functionalized silica employed, and platinum loading. Efforts are underway to synthesize a stand-alone mixed conducting support by combining the methods described herein. Work will be performed collaboratively with NTCNA to subject the supports synthesized to a more diverse set of stability testing protocols.

Project End Date: August 1, 2014

- (B) Cost (reduce precious metal loading of catalysts)
- (C) Performance (increase the specific and mass activities of catalysts)
- (A) Durability (increase the durability/stability of catalysts with cycling)

Technical Targets

TABLE 1. Progress towards Meeting Technical Targets for Non-PGM Electrocatalysts for Transportation Applications

Characteristic	Units	2015 Target	NEU 2011 status
Specific Activity @ 80°C, 0.1 M HClO ₄	A/cm ³	150/300	30
Specific Activity @ 80°C, 150 kPa, H ₂ /O ₂ , 100% relative humidity (RH)	A/cm ³	150/300	130
Durability at 80°C Cycling: Catalyst Durability	% loss of activity	5	<1
Durability at 80°C Cycling: Carbon Corrosion Durability	% loss of activity	10	<50

FY 2011 Accomplishments

- Current efforts focus on synthesis of non-PGM metals contained in unique liganded environments (mostly using N or O) and its incorporation onto carbon supports for effecting improved oxygen reduction reaction (ORR) performance and stability. Such as those shown by the LANL group.
- Our effort encompasses development of novel bi-dentate and tetra-dentate complexes where tandem electron transfer to oxygen can be facilitated using two or three transition metals with different oxidation states.
- Successful implementation of these strategies has been done at NEU as well as partner institutions which include UTK, UNM and MSU.
- One such rendition of a ligand Fe-based catalyst has also been extensively tested at NTCNA for both fuel cell activity as well as durability. The latter tests involved both catalysts and support stability tests incorporating DOE mandated cycling tests.
- Current status of the non-PGM field puts the volumetric power density at 130 A/cm³ this however needs to be translated to actual fuel cell performance levels which requires redesign of electrode structures. In addition, excellent durability of the tested catalysts is reported.

Fiscal Year (FY) 2011 Objectives

The objective of this project is to design non-platinum group (PGM)-based materials and supporting gas transport layer, both in the interfacial reaction layer between the electrode and membrane as well as in the underlying gas diffusion medium, for meeting and exceeding DOE goals for application in solid polymer electrolyte fuel cells. This project is focused on materials development and is assisted by advanced analytical tools, computation, and testing for improving the design via critical understanding of electrocatalysis in these novel structures.

Technical Barriers

This project addresses the following technical barriers from the Fuel Cells section of the Fuel Cell Technologies Program Multi-Year Research, Development and Demonstration Plan:

Introduction

Polymer electrolyte membrane fuel cells (PEMFCs) are promising candidates as an alternative to traditional energy converters. A primary technical challenge faced in the development of the technology is the sluggish kinetics of the ORR on the cathode. Pt and Pt alloy electrocatalysts remain the choice of electrocatalysts for PEMFCs due to the so called “stability criterion.” However, recent reports have shown good activity and stability for alternative non-PGM-based electrocatalysts [1] and Dodelet [2] for the more challenging ORR.

Approach

The objective of this project is to design non-PGM-based materials and supporting gas transport layer, both in the interfacial reaction layer between the electrode and membrane as well as in the underlying gas diffusion medium, for meeting and exceeding DOE goals for application in PEMFCs. This project is focused on materials development and is assisted by advanced analytical tools, computation, and testing for improving the design via critical understanding of electrocatalysis in these novel structures.

Results

UNM explored the effect of support material for the catalyst. It was shown that templating catalysts onto a sacrificial layer of hierarchically structured silica (HSS) or fumed silica allows synthesis of materials with well developed porosity, this cannot be achieved with synthesis methods based on use of carbon black. These HSS materials also offer higher surface areas when compared to catalysts supported on carbon blacks. After etching silica, the cavities left by the vacated silica create an open-framed structure that upon addition of catalysts allows for internal transport of electrolyte and reactant, providing additional surface area for the active sites. Two classes of catalysts were synthesized and characterized: Fe-cyanamide and Fe-4-aminoantipyrene diethanolamine. It was found that heat treatment conditions including ramp rates, durations, and temperatures can have dramatic effects on final catalytic activity, and should be optimized for every combination of Fe and C-N precursors. Furthermore, the density functional theory computations show that nitrogen may play a dual role in non-Pt ORR electrocatalysts: on the one hand it provides a stabilizing coordination environment for transition metals such as cobalt or iron. On the other hand, the ability to stabilize narrow channels due to balancing nitrogen and cobalt content indicates that nitrogen can help stabilize microstructures. The investigated catalysts show significant activity towards oxygen reduction and can be used as inexpensive substitutes for Pt.

The effect of the nitrogen precursor was explored by the team from MSU. Metal-nitrogen-carbon cathode catalysts for the ORR in low temperature fuel cells were synthesized by pyrolysis of iron-acetate, Ketjen black and various nitrogen precursors of varying nitrogen content, including carbon-free nitrogen precursors. In collaboration with UNM a surface analysis was carried out to determine the surface nitrogen content produced by the various precursors. These results were combined with ORR activity results to determine what type of nitrogen precursor produced the best performing catalyst.

In addition, two sample catalysts from MSU that were prepared from melamine and ammonium carbamate precursors were sent to NTCNA Fuel Cell Laboratory for ex situ and in situ characterization.

Understanding the selectivity of the catalyst towards two or four electron pathways is very important for oxygen reduction catalysts. Rotating ring disk electrode (RRDE) experiments were performed for the melamine-based catalyst to verify the formation of peroxide. Peroxide formation was observed to be less than 2% (DOE Target).

Fuel cell testing was carried out and current-voltage (I-V) performance was measured at both atmospheric and 1 bar pressure, 80°C, 100% RH. The high frequency resistance of this MEA was very high due to the amount of ionomer in the catalyst layer and the catalyst layer's thickness. As expected, HFR measured at 1 bar was higher than at atmospheric pressure. These are shown as I-V curves both on a linear and corresponding semi-logarithmic Tafel plots in Figures 1 and 2, respectively. Volumetric activity or volumetric current density is calculated at 0.8 V internal resistance-free voltage and an effective carbon density of 0.4 g/cm³ was assumed for these calculations. Volumetric current densities of 31 and 131 A/cm³ were obtained for the melamine-based catalyst MEA without pressure and with

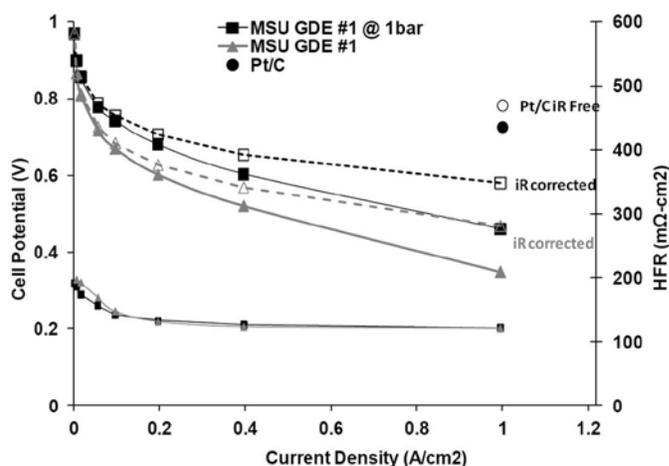

FIGURE 1. I-V performance for Fe-N_x-based catalysts using melamine precursors with (■ and □) and without (▲ and △) back-pressure (100 kPa) conditions under 100% RH, 80°C, and H₂/O₂.

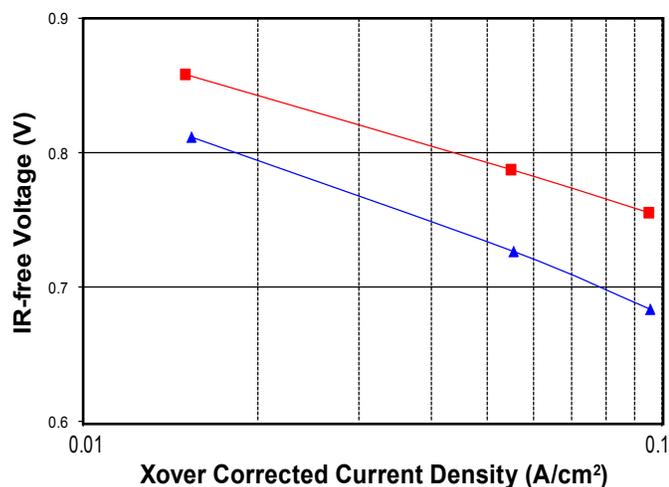

FIGURE 2. Corresponding Tafel Plots for Fe-Nx catalysts prepared using melamine precursors, with (red) and without (blue) back pressure (150 kPa). Plots reflect internal resistance correction and adjustment for hydrogen cross over.

back-pressure of 1 bar, respectively. However, at 80°C under H₂/air with 100% RH or 50% RH, this MEA showed very poor performance.

In situ durability tests were performed on the same MEA (Fe-N_x melamine precursor sample) which was used to evaluate I-V performance (Figures 1 and 2). Two types of in situ durability tests, namely load cycling and start-stop cycling (10,000 cycles) were performed. The first referred to as catalyst durability test (or Pt dissolution protocol in NTCNA parlance) involved square wave potential cycling tests in the range of 0.6 and 1.0 V with 3 s on and 3 s off periods (Figure 3). The same MEA used for support durability tests, here cycling were used in the range of 1.0 and 1.5 V in a triangular profile (Figure 3) referred to as carbon corrosion test. In this case, the open circuit voltage value did change due to the potential cycling resulting in carbon loss.

The I-V performance curves were recorded before and after these durability tests. Catalyst durability cycling showed minimal effect on I-V performance with and without back-pressure. However, carbon corrosion test cycling

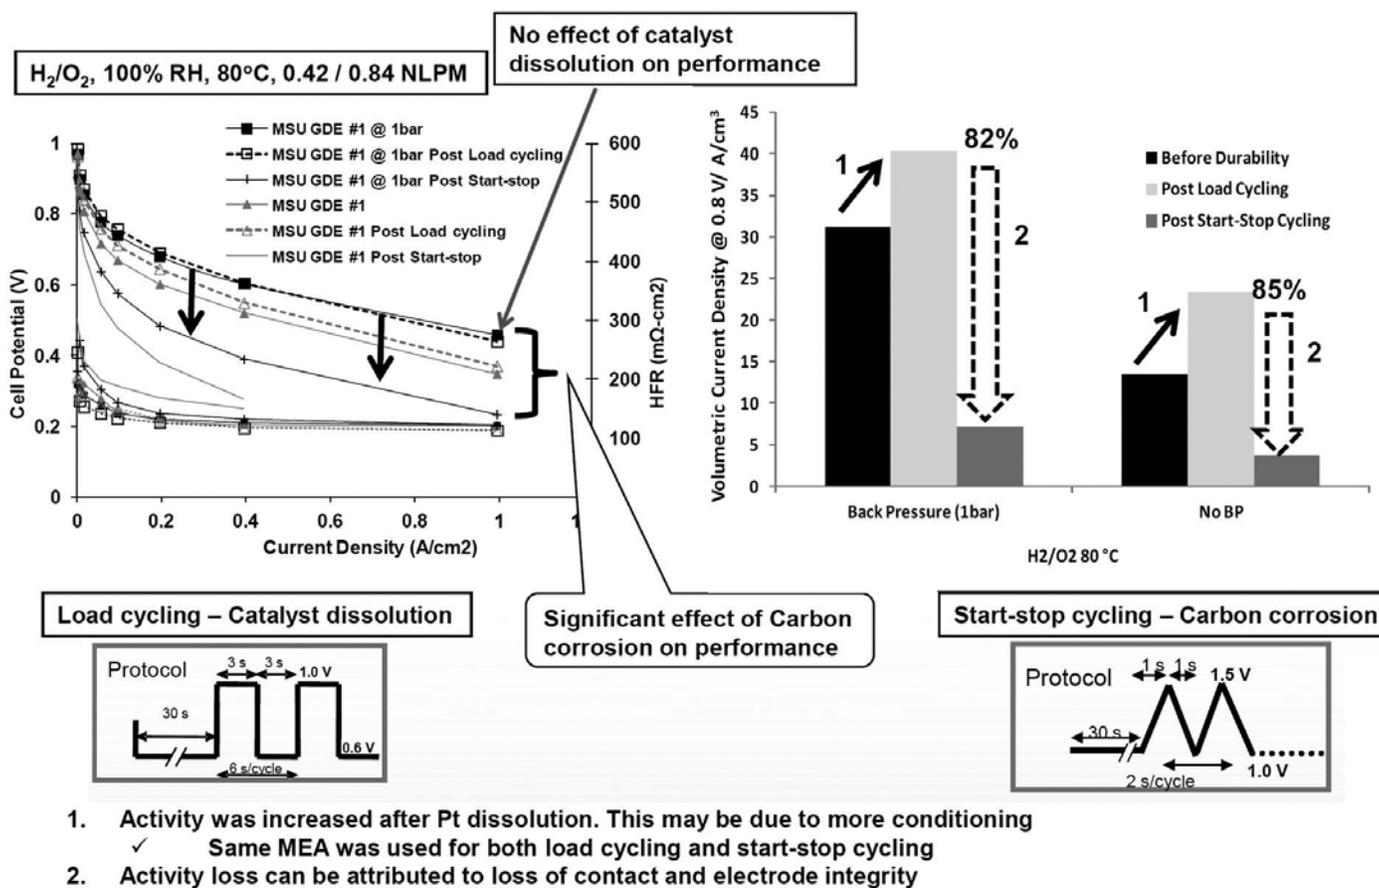

FIGURE 3. Durability tests in single cells (80°C, 100% RH, with and without backpressure, 150 kPa). Two protocols were (a) catalysts durability involving cycling between 0.6 and 1.0 V in a square wave profile with 3 s on and 3 s off periods and (b) carbon corrosion tests between 1.0 and 1.5 V in a triangular profile.

showed significant drop in performance under both pressure conditions. The drop in performance due to start-stop cycling can be attributed to formation of surface oxides on the carbon surface making it hydrophilic in nature. Also, loss in carbon causes a decrease in the electronic conductivity resulting in lower performance which can be observed in the kinetic region.

Conclusions and Future Directions

- A multipronged effort involving several different chemistries is being pursued for the effective development of a non-PGM-based oxygen reduction catalyst.
- Initial results have shown good performance both in RRDE as well as fuel cell test conditions. Performance of 130 A/cm³ is reported based on projections in a single-cell test conducted at NTCNA. This is close to the 2010 DOE non-PGM target.
- Excellent catalyst durability is reported using NTCNA/DOE cycling protocols, however significant carbon corrosion is measured which needs to be addressed via modifications in pretreatments to carbon blacks, use of grapheme-based materials as well as stable transition metal oxide supports.

- Technical University Berlin (TUB), Berlin, Germany

Project Start Date: August 1, 2010
 Project End Date: May 31, 2013

Objectives

- Prepare, characterize, and test dealloyed catalysts with initial oxygen reduction mass activities exceeding the DOE 2015 target of 0.44 A/mg_{Pt} at 900 mV reversible hydrogen electrode in 50 cm² fuel cells.
- Demonstrate, for these materials, loss of no more than 40% of the catalytic (mass) activity after the DOE-specified voltage-cycling test in 50 cm² fuel cells.
- Develop and demonstrate, with these catalysts, electrodes giving high current density performance in air adequate to meet the DOE platinum group metal (PGM) loading targets of <0.125 g_{PGM}/kW_{rated} and <0.125 mg_{Pt}/cm²_{geo}.
- Demonstrate durability of the high current density performance in air in full-active-area fuel cells.
- Determine, at the atomic scale, where alloying-element atoms should reside with respect to the surface of the catalyst particle for simultaneously good activity, durability, and high-current density performance in air.

Technical Barriers

This project addresses the following technical barriers from the Fuel Cells section of the Hydrogen, Fuel Cells and Infrastructure Technologies Program Multi-Year Research, Development and Demonstration Plan:

- Durability
- Cost
- Performance

Technical Targets

} For more highly dealloyed PtCu₃

PGM - platinum group metal

Fiscal Year (FY) 2011 Accomplishments

- Demonstrated in 50 cm² fuel cells a dealloyed PtCu₃ catalyst with initial mass activity of 0.58 A/mg_{Pt}, exceeding the DOE 2015 target of 0.44 A/mg_{Pt}.
- Demonstrated in 50 cm² fuel cells a dealloyed PtCo₃ catalyst with a loss of 38% of its initial mass activity after 30,000 cycles 0.6-1.0 V in H₂/N₂, (slightly) bettering the DOE 2015 target of <40% loss. The initial activity of this PtCo₃ catalyst, at 0.37 A/mg_{Pt}, tested slightly below the DOE target for initial activity.
- Developed methods to scale up the production of relevant catalyst precursors from <0.5 g to 100 g.
- Derived similar ~3 monolayer Pt shell/PtCu_{1.8} core structures from transmission electron microscopy (TEM) and extended X-ray absorption fine structure for a dealloyed PtCu₃ catalyst.

Introduction

The amount of expensive platinum used in the air electrode of fuel cells must be reduced at least 4-fold to make fuel cells cost-competitive with internal combustion powertrains, requiring a compensating increase in the oxygen reduction activity per gram of Pt used. Pt-alloy catalysts have historically given a ~2-fold increase in activity vs. pure Pt, leaving a 2-fold gap remaining. However, prior to this project the group of project team member Peter Strasser (now at TUB) had found in laboratory experiments that if one started with a large excess of the inexpensive non-noble alloying element and then removed most of that element with an electrochemical voltage-cycling “dealloying” treatment, significantly enhanced activities exceeding the DOE 2015 target of 0.44 A/mg_{Pt} could be achieved [1]. This project seeks to develop and scale up new catalysts that take advantage of this activity gain from dealloying while also achieving the durability and high current density performance needed for production fuel cells.

Approach

Catalyst precursors with the general formulation PtM₃ are being prepared on carbon-black supports, with the choices of M including Cu, Co, Ni, and possibly Fe and V. Electrochemical and chemical processes have been developed to partially dealloy the precursor powders down to a composition of ~Pt₂M. This must be done prior to incorporation of the catalysts into a membrane electrode assembly (MEA) to prevent excessive displacement of hydrogen ions from the ion-exchange sites of the ionomer by M^{x+} ions. This project has scaled up the production of relevant catalyst precursors from a <0.5 g level to the >100 g needed for durability and integration studies. Dealloying methods more suitable to eventual mass production have been developed and are being further optimized.

The catalysts are then tested for oxygen reduction kinetic activity on rotating-disk electrodes (RDEs) and for both activity and durability in 50 cm² fuel cells. Advanced TEM and X-ray absorption spectroscopy (XAS) techniques are being applied to fresh and used catalyst samples to determine atomic-scale composition and structure. Iterative cycles of synthesis, testing, and characterization are being used to optimize the dealloyed catalysts. We plan to achieve durability by leaving just the right number of M atoms, and no more, at just the right places in the catalyst particles. At the end of the project, downselected catalysts will be fabricated into full-active-area fuel cell short stacks to test the durability of high current density performance while operating with hydrogen/air.

Results

Figure 1 shows that in 50 cm² MEAs in H₂/O₂ fuel cells under standard conditions, GM has obtained initial mass activities of 0.58 A/mg_{Pt} at 900 mV for catalysts prepared

from PtCu₃/HSC precursors from the Strasser group using a readily manufacturable chemical dealloying process applied to the precursor powder. This value exceeds the DOE target of 0.44 A/mg_{Pt}. A scaleable, though still less convenient, electrochemical dealloying procedure applied to the powder gave 0.32 A/mg_{Pt}. While the initial activity target has been reached with the chemically-dealloyed material, the Strasser group had been able to prepare precursors to highly active dealloyed catalysts only in batches of ≤0.5 g (with thermal annealing being the scale-limiting step), severely limiting the amount of fuel cell testing that could be done. JMFC’s initial attempts to scale up (to >80 g) the annealing of PtCu₃ precursors under this project led to materials with badly diminished surface areas. After intense study of preparation techniques, including thermal gravimetric analysis, JMFC developed modified preparation procedures at the 100-g scale that can reproduce the physical properties of Strasser’s small batches. GM applied its chemical dealloying procedures to this large-batch PtCu₃/Ketjen precursor, generating catalysts that show a laboratory RDE activity of 0.52 A/mg_{Pt}, in good agreement with RDE results from the Strasser small batches. However, the first 50 cm² MEAs made from the large JMFC batch of PtCu₃ have given mass activities of only 0.26 A/mg_{Pt}. While it is unfortunately common to measure lower activities for a catalyst in real fuel cells than in RDE, that had not been the case for the Strasser small batches. The dealloyed JMFC PtCu₃ has a higher electrochemical surface area (93 m²/g_{Pt}) than the Strasser small batch (67 m²/g_{Pt}), so it may prove useful for JMFC to slightly raise their annealing temperature.

While the dealloyed PtCu₃ gave very good initial oxygen reduction reaction activity, Figure 2 shows that it lost 82% of its initial activity after 10,000 potential cycles 0.6-1.0 V

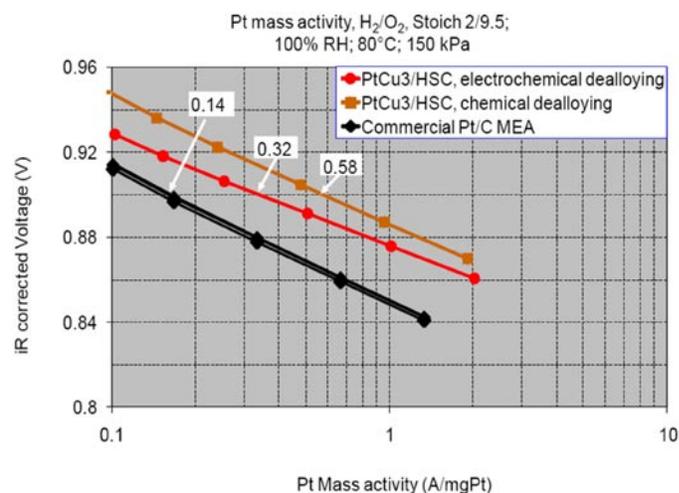

FIGURE 1. Oxygen reduction activity in 50 cm² fuel cells (targets at 0.90 V) for Strasser-group PtCu₃ precursor dealloyed by chemical or electrochemical methods at GM, plus pure-Pt-catalyzed commercial MEAs for comparison, at the standard conditions shown. X-axis is the current density (A/cm²_{geo}) divided by the Pt loading (mg_{Pt}/cm²_{geo}).

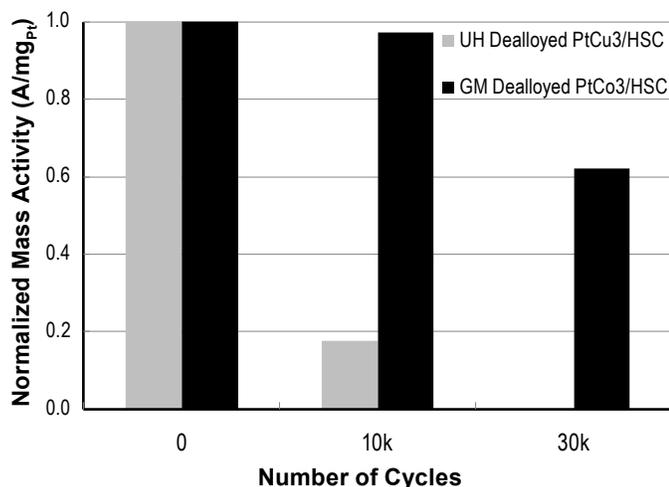

FIGURE 2. Mass activities for dealloyed PtCu₃ and dealloyed PtCo₃ catalysts, normalized to initial values, after indicated number of potential cycles 0.60-1.00 V in H₂/N₂ 50 cm² fuel cells. Activities measured in H₂/O₂ under conditions of Figure 1.

in 50 cm² H₂/N₂ fuel cells. In contrast, Figure 2 also shows that a GM-prepared dealloyed PtCo₃/HSC catalyst lost only 38% of its initial activity after 30,000 cycles, meeting the DOE target of a <40% loss. Since the initial activity of the dealloyed PtCo₃, 0.37 A/mg_{Pt}, did not quite meet the initial activity target, we have one catalyst satisfying initial activity (PtCu₃) and a different one satisfying durability (PtCo₃) targets. Dealloyed PtCo (lower initial Co) has given 0.48 A/mg_{Pt} under slightly different test conditions.

Through detailed analysis by XAS and several forms of high resolution TEM, we seek to determine which atomic-scale structural and compositional structures confer high activity and which improve durability. With such knowledge in hand, we should be able to prepare catalysts simultaneously satisfying both targets. Our initial XAS and TEM work with dealloyed PtCu₃ showed a preponderance of particles with a core of a ~PtCu_{1.8} alloy surrounded by a shell of three monolayers of pure Pt. Preliminary analysis of similar data for dealloyed PtCo₃ suggests the presence of thicker Pt shells. Given that the enhanced activity of the surface Pt atoms is believed to arise from lattice-compression [2] and/or direct electronic effects of the non-Pt atoms in the cores, and that these non-Pt atoms are much more susceptible to corrosion, one might expect an increase in shell thickness activity to decrease activity and increase durability, consistent with our preliminary structural observations. However, other parameters being measured (listed below under Conclusions) may exert more direct control than shell thickness. The knowledge gained from the characterization work is guiding our synthetic efforts in an iterative process.

Pre-project work at TUB suggested that dealloyed PtNi₃ could be more stable than PtCo₃, with at least

equivalent activity. TUB and JMFC have developed independent methods to prepare a single-phase (helpful for the production of the uniform catalyst particles needed for definitive experiments) PtNi₃ precursor. Initial GM RDE experiments on JMFC small-batch dealloyed PtNi₃ have given activities of 0.33 A/mgPt, but no optimization has yet been done on this system.

Excess non-noble metal ions leached from the catalyst can suppress oxygen reduction performance at high current density [3]. We have so far observed a negative correlation between high-current-density performance and the amount of M left in the catalyst after dealloying. We are working to identify just the right number of M atoms, in just the right place in the particle, needed for maximum durable activity, and then to synthesize particles with no excess M.

Conclusions and Future Directions

- A dealloyed catalyst (PtCu₃) has met the DOE target for oxygen reduction mass activity.
- A different dealloyed catalyst (PtCo₃) has met the DOE target for retention of mass activity after voltage cycling.
- The primary goal for 2011 is to achieve both initial activity and durability targets with the same catalyst, learning from the detailed atomic-scale characterization work.
- Dealloying produces a range of structures featuring pure-Pt shells over M-rich alloy cores.
- The following parameters are being measured, and varied via synthesis, to determine which best correlate with activity and durability: lattice compression in Pt shell, shell thickness, M concentration in core, average Pt d-band vacancy population, and particle size.

Project Start Date: September 1, 2010
 Project End Date: May 31, 2014

Fiscal Year (FY) 2011 Objectives

- Develop low cost and durable hybrid cathode catalyst (HCC).
- Develop Pt alloy/activated graphitic carbon (AGC) catalyst.
- Develop corrosion resistant supports.
- Develop facile scale-up catalyst synthesis procedure (at least 100 g).
- Optimize the parameters which control the number of catalytic sites on carbon composite catalyst (CCC).
- Optimize the procedure for the formation of more active Pt alloy catalysts.
- Demonstrate kinetic mass activity in H₂/O₂ fuel cell higher than DOE target of 0.44 A/mg_{PGM} and durability of the mass activity.
- Demonstrate high current performance in H₂/air fuel cell to meet DOE targets.
- Construct short-stack (50 cm² up to 10 cells) and evaluate the performance under simulated automotive conditions.

Technical Barriers

This project addresses the following technical barriers from the Fuel Cells section of the Fuel Cell Technologies Program Multi-Year Research, Development and Demonstration Plan:

- Durability
- Cost
- Performance

Technical Targets

The expected outcome of the project is the fabrication of catalysts, fully integrated into a proton exchange membrane electrode assembly (MEA), with the following performance characteristics:

- PGM loading of 0.1 mg/cm².
- Mass activity of 0.44 A/mg_{Pt} at 0.9 V_{iR-free}.
- Specific activity of 720 μA/cm² at 0.9 V_{iR-free}.
- Mass activity of at least 0.24 A/mg_{Pt} after 30,000 cycles, DOE protocol (0.6-0.9 V).
- Initial high current density performance of 1.5 A/cm² at 0.56 V_{iR-free} in H₂-air.
- Electrochemical surface area (ECSA) loss less than 40% of initial catalytic activity after 30,000 cycles.
- Short-stack specific power density of 0.1 g/KW at rated power.
- Durability under cycling transportation conditions at ≥80°C for 2,000 hours and at ≤80°C for 5,000 hours.
- High volume production (manufacturability).

TABLE 1. Progress towards Meeting Technical Targets for Electrocatalysts for Automotive Applications

Characteristic	Units	Target 2015	USC 2011 status (25 cm ² cell)
PGM Total Content	g/kW rated	≤0.125	To be determined
PGM Total Loading	mg PGM/cm ² electrode area	≤0.125	0.1 (anode)/ 0.1 (cathode)
Loss in Catalytic (mass) Activity	percentage	<40% loss of initial	34%
Current Density Performance in H ₂ /Air	A/cm ² at 0.56 V _{iR-free}	1.5 A/cm ²	1.45 (Pt ₃ M ₁ /AGC)
Mass Activity	A/mg PGM @ 900 mV _{iR-free}	≥0.44	0.43 (PtM ₂ /C) 0.42 (Pt/CCC [HCC]) 0.41 (Pt ₃ M ₁ /AGC)
Specific Activity	μA/cm ² @ 900 mV _{iR-free}	720	1135 (Pt ₃ M ₁ /AGC)

FY 2011 Accomplishments

- Accomplished onset potential for oxygen reduction on CCC close to 0.9 V and less than 2.5% of peroxide production.
- Accomplished mass activity of 0.43 A/mg_{Pt}, 0.42 A/mg_{Pt} and 0.41 A/mg_{Pt} for PtM₂/C, Pt/CCC (HCC) and Pt₃M/AGC catalysts, respectively.
- Achieved durability of kinetic mass activity of 0.27 A/mg_{Pt} after 30,000 cycles for Pt₃M₁/AGC catalyst in 25 cm² cell.
- Accomplished initial high current density of 1.45 A/cm² at 0.56 V_{ir-free} in H₂-air for Pt₃M₁/AGC catalyst.

Introduction

Stable and highly active HCC was developed at USC which shows higher performance than the commercial Pt/C at low loadings (between 0.04 and 0.4 mg/cm²). The hybrid cathode catalyst is a combination of nitrogen-containing CCC, developed at USC, and platinum for oxygen reduction reaction [1-10]. Yonsei University developed a procedure for the synthesis of leached Pt-alloy catalysts deposited on AGC. Furthermore, Pt dendrites with controlled size have been developed for oxygen reduction reactions (ORR) [11-13]. The dendrites show superior activity for ORR and better selectivity when compared to the commercial Pt/C catalyst. HMC optimizes the design of 50 cm² active area bipolar plates and short stack assembly.

Approach

Currently, the main strategies to decrease the platinum loading in cathode electrodes are based on the optimization of electrode structures and implementation of more active Pt alloy catalysts. The new approach used in this work consists of development of a HCC through USC's patented process. The synergetic effect present in HCC results from contribution of the active sites present in CCC which improve the catalyst performance at low potentials, while implementation of Pt or leached Pt-alloy active sites increase the mass activity at high potentials. The goal of our second strategy is the synthesis of Pt-alloy catalysts deposited on AGC. To overcome the drawbacks associated with carbon corrosion under automotive operating conditions, corrosion-resistant catalyst support based on TiO₂ and corrosion-resistant hybrid TiO₂-CCC are under development at USC. HMC optimizes the design of 50 cm² active area bipolar plates and short stack assembly.

Results

In this reporting period, Pt/CCC (HCC) and PtM₂/C alloy catalysts were synthesized at USC. Pt and Pt-alloy catalysts deposited on AGC were developed at Yonsei

University. HMC optimized the flow-field design of 50 cm² active area bipolar plates and short stack assembly. The performance of the catalysts including ECSA, kinetic mass activity, catalyst durability after 30,000 cycles, specific activity and initial high current performance were evaluated using rotating ring disc electrode and in a proton exchange membrane fuel cell (PEMFC).

Figure 1 shows the X-ray diffraction (XRD) of HCC catalyst and the cross-sectional analysis of MEAs utilizing different loadings of HCC catalyst. Shift of the diffraction peaks to higher Bragg angles indicates a decrease in the lattice constant due to alloy formation during the heat treatment. The ECSAs of the HCC catalyst and Pt/C catalyst were calculated to be 102 and 97.2 m²/g, respectively.

PtM₂/C alloy catalyst was synthesized by depositing a protective layer on the surface of Pt/C to inhibit Pt particle agglomeration during high temperature alloying process. XRD showed slight shift of the diffraction peaks towards higher angle which confirms the lattice contraction even after chemical leaching procedure. With the protecting layer, there is no change of the Pt peak width and intensity suggesting the small change of the Pt particle size after high temperature alloying procedure. The average Pt particle sizes of Pt/C, Pt/C heated at 800°C, and de-alloyed PtM₂/C catalysts are 3, 22.2 and 3.3 nm, respectively. The results show that the Pt particles agglomerated during high temperature heat treatment in the absence of protecting layer. The ECSAs of the 60% Pt/C and 60% PtM₂/C catalysts are calculated to be 56.6 and 40.7 m²/g, respectively.

Figure 2 compares the mass activities of HCC, PtM₂/C and commercial Pt/C catalysts. The cathode catalyst loadings were maintained at 0.1 mg/cm². Nafion[®] NRE 212 membrane was used for making the MEAs. As shown in Figure 2, the kinetic mass activities of 0.43 A/mg_{Pt} and 0.42 A/mg_{Pt} were estimated for 60% PtM₂/C and 40% HCC catalyst, respectively. The mass activity of 45.9% commercial Pt/C catalyst is 0.154 A/mg_{Pt}.

A new method was developed to functionalize the graphitic carbon through the non-covalent π - π interaction using a bifunctional molecule namely, 1-pyrenecarboxylic acid (1-PCA). The results indicated that this molecule irreversibly adsorbs on the inherently hydrophobic surfaces of carbon nanofibers (PCA-CNFs). The results revealed that the Pt nanoparticles deposited on PCA-CNF are uniformly distributed on the CNFs, with no agglomeration. The average Pt particle size was 2.0 ± 0.2 nm which is smaller than the particle size observed on the raw CNF. The Pt content loaded on 1-PCA treated CNF was 38 wt%, which is much higher than the raw CNF (18 wt%).

To inhibit the agglomeration of Pt particles during the high temperature alloying process, a new impregnation method was developed at Yonsei University to synthesize platinum alloy particles to be uniformly distributed on the support. The Pt-alloy particle size was calculated from the XRD. The normal heat-treatment of commercial

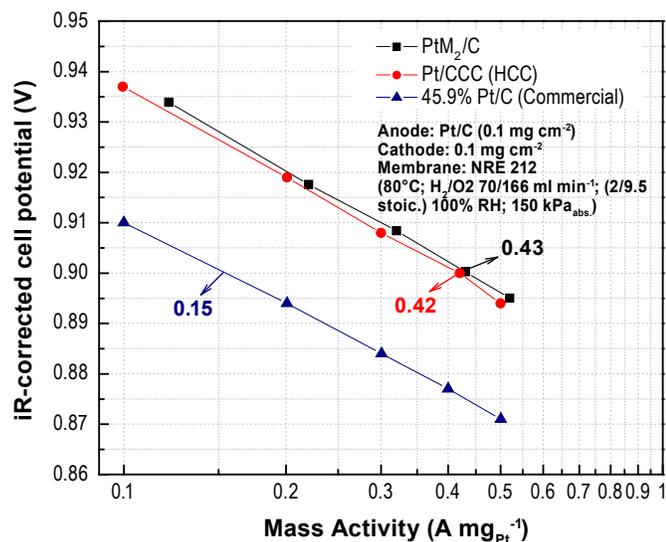

FIGURE 2. Mass Activity Comparison of Pt/CCC (HCC), PtM₂/C and Commercial Pt/C Catalysts

50% Pt₃M₁/C resulted in 10.8 nm particles while the 50% Pt₃M₁/AGC synthesized in this study resulted in 3.4 nm

particles. The aggregation of Pt particles was restrained by the protective film used in this study.

The performance of commercial Tanaka Kikinzoku Kogyo K. K. (TKK) 40% Pt/C, 46% Pt/C, and 50% Pt₃M₁/AGC as cathode catalysts was investigated in a PEMFC. The ECSA measured in a three electrode system and fuel cell was used to estimate the catalyst utilization. The utilization ratio for Pt₃M₁/AGC catalyst was estimated to be 88% which is higher than that of TKK 40 wt% Pt/C (76%) and TKK 46 wt% Pt/C (56%). The utilization of 88% observed for the in-house synthesized catalyst is due to better Pt-alloy particle distribution on PCA modified graphitic carbon nanocage which was used as a catalyst support.

To optimize the protecting coating process, Pt₃M₁/AGC catalyst was synthesized with different mass ratio (25, 50 and 60% on a carbon support). XRD was used to determine the alloy particle size. No extra peaks assigned to M₁ or M₁-oxides were identified. The results indicated that a high degree of alloying is present for Pt₃M₁/AGC catalysts. The particle sizes of the Pt₃M₁/AGC catalysts were calculated to be 3.2, 3.4 and 4.1 nm at catalyst loading of 25%, 50% and 60% on the carbon support, respectively.

The performance of the catalysts was estimated from the polarization curves and evaluated based on the mass activity

(A/mg_{PGM} @ $900\text{ mV}_{iR-free}$) and the specific activity ($\mu A/cm^2$ @ $900\text{ mV}_{iR-free}$). The specific activity of 50% Pt_3M_1/AGC is $1,023\ \mu A/cm^2$, which is higher than the DOE target ($720\ \mu A/cm^2$). The ECSA of the catalyst used to calculate the specific activity was obtained from the MEA.

The durability of 50% Pt_3M_1/AGC catalyst was evaluated using DOE cycling protocol. The active area of the MEA was 25 cm^2 . The cathode was cycled under N_2 (relative to the anode under H_2) 30,000 times between 0.6 and 1.0 V at a sweep rate of 50 mV/s. Cell diagnostics of the cathode catalyst such as ECSA, ORR mass activity, and oxygen polarization curves were performed after 3,000, 10,000, 20,000, and 30,000 cycles. The activity of the catalyst was evaluated based on its mass activity. Figure 3 shows the iR -corrected polarization curves under H_2O_2 and 100% relative humidity. The fuel cell operating conditions are given in the graph. The initial mass activity and the mass activity loss after 10,000 and 30,000 cycles are also presented in Figure 3 (inset). The mass activity loss of 50% Pt_3M_1/AGC is 34% which is lower than the DOE target (40% loss). The ECSA loss is only 30% (decreased from 29.5 to 20.8 m^2/g after 30,000 cycles). The DOE target is less than 40%. Comparison of H_2/air fuel cell performance at high current densities of commercial Pt/C and Pt_3M_1/AGC catalyst is shown in Figure 4. Fuel cell operating conditions are shown in the figure.

Conclusions and Future Directions

Accomplishments in the reporting period:

- Achieved onset potential for oxygen reduction close to 0.9 V and less than 2.5% peroxide formation for CCC.

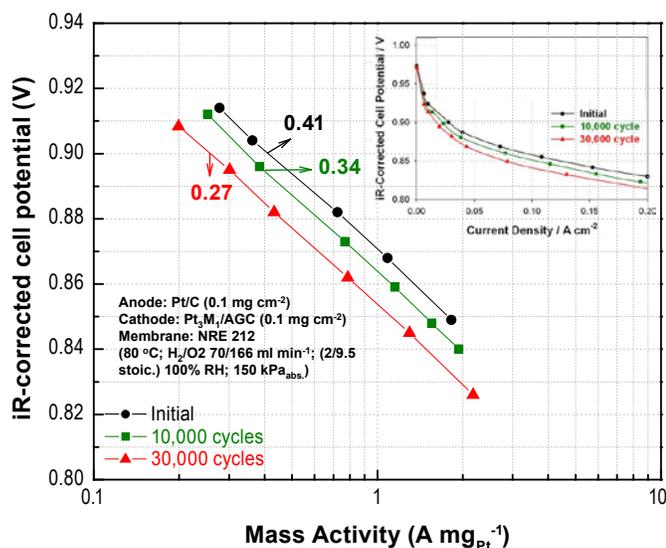

FIGURE 3. Mass Activities of 50% Pt_3M_1/AGC Catalysts as a Function of Number of Cycles (The iR -corrected polarization curves obtained for 50% Pt_3M_1/AGC as function of number of cycles is shown in the inset.)

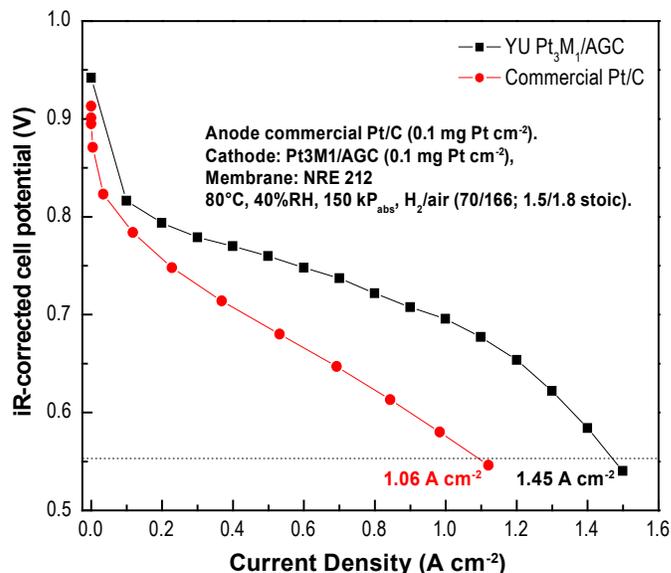

FIGURE 4. Comparison of H_2/air Fuel Cell Performance of Commercial Pt/C and Pt_3M_1/AGC Catalysts

- The kinetic mass activities of 0.43 A/mg_{Pt} , 0.42 A/mg_{Pt} and 0.41 A/mg_{Pt} were estimated for 60% PtM_2/CCC , 40% HCC catalyst and 50% Pt_3M_1/AGC catalyst, respectively compared with mass activity of 45.9 % commercial Pt/C catalyst is 0.154 A/mg_{Pt} .
- The specific activity of 50% Pt_3M_1/AGC synthesized at Yonsei University is $1,023\ \mu A/cm^2$, which is higher than the DOE target ($720\ \mu A/cm^2$).
- The mass activity loss after 30,000 cycles, DOE protocol (0.6-0.9 V) of 50% Pt_3M_1/AGC is 34% is lower than that the DOE target (40% loss).
- The ECSA loss for the same catalyst is only 30% (decreases from 29.5 to 20.8 m^2/g) after 30,000 cycles. The DOE target is less than 40%.

Future anticipated accomplishments are to:

- Achieve ultra-low Pt HCC catalysts for oxygen reduction reaction with mass activity larger than 0.44 A/mg_{Pt} and durability of 0.24 A/mg_{Pt} after DOE suggested potential cycling (0.6 to 1 V) (USC).
- Develop activated high surface area Pt catalyst through synthesis of Pt-alloy catalyst using in-house developed procedures (Yonsei University and USC).
- Accomplish high current density performance and durability in H_2/air fuel cells to meet the DOE targets (USC and Yonsei University).
- Develop support which will increase the catalyst utilization and eliminate the loss of ESCA through: performance optimization of CCC, stable conductive TiO_2 and CCC- TiO_2 hybrid supports developed at USC and modified graphitic carbon developed at Yonsei University. (USC, Yonsei University and HMC)

- Evaluation of MEA and fuel cell stack: To perform accelerated durability tests of MEAs with commercial catalyst to optimize the design of 50 cm² active area bipolar plate flow field and short stack assembly (HMC).

Start Date: September 2009

Project End Date: 2013

Fiscal Year (FY) 2011 Objectives

- Develop a ceramic alternative to carbon material supports for a polymer electrolyte fuel cell cathode.
- Ceramic support replacement for carbon must:
 - Have enhanced resistance to corrosion and Pt coalescence.
 - Preserve positive attributes of carbon such as cost, surface area, and conductivity.
 - Be compatible with present membrane electrode assembly (MEA) architecture and preparation methods.
- Ceramic properties goals:
 - High surface area
 - High Pt utilization
 - Enhanced Pt-support interaction
 - Adequate electronic conductivity
 - Corrosion resistance
 - Synthetic methods amenable to scale up
 - Reasonable synthesis costs

Technical Barriers

This project addresses the following technical barriers from the Fuel Cells section of the Fuel Cell Technologies Program Multi-Year Research, Development and Demonstration Plan:

- (A) Durability: Pt sintering, corrosion loss, effects from load-cycling and high potential.
- (B) Cost: Better Pt utilization balanced by cost difference of new support vs. carbon.
- (C) Performance: Pt sintering, corrosion loss, and loss of electroactive surface area.

Technical Targets

- Precious metal loading (0.2 mg/cm²)
- Cost (<\$3/kW)
- Activity (0.44 A/mg_{Pt} @ 0.9 V_{iR-free})
- Electrocatalysis support loss (<30 mV after 100 hrs @ 1.2 V)
- Electrochemical surface area loss (<40%) tested per GM protocol (Mathias, M.F., et al., Interface [Electrochemical Society], Fall 2005, p. 24)

FY 2011 Accomplishments

Synthesis of Non-Carbon Support Materials

- “Go” decision made for Mo₂N supports synthesized via polymer assisted deposition (PAD) approach: ahead of schedule.
 - Quarter (Q)8 target moved up to Q5-Q6.
- Evaluation of titania supports prepared by PAD approach ahead of schedule.
 - Q6 targets moved up to Q3-Q4.
- Go/No-Go decision on hexaboride supports: ahead of schedule.
 - No-Go: Q6 decision moved up to Q4.
 - Unable to synthesis using aerosol through plasma (A-T-P) process (Q4).
 - PAD process produced only small amounts of LaB6 (Q6).
- Performance evaluation of Pt/NbRu_yO_z catalysts: ahead of schedule.
 - No-Go: poor activity due to formation of NbOx passivation layer on Pt (Q6).

Testing, Characterization and Evaluation

- Full electrochemical characterization of Mo₂N support and its precursors with and without platinum in organic and aqueous solutions.
- Initial electrochemical characterization of TiO and TiO₂ supports.

Theory and Computation

- Calculations were performed using plane wave periodic density functional theory to create a structural model of gamma Mo_2N : NaCl structure with half of the nitrogen sites vacant creating MoN and Mo-rich surfaces for Pt adhesion.
- The most favorable sites for single Pt atoms and a monolayer was constructed based on these results.
- Nitrogen depleted surface layer on the Mo_2N promotes stronger binding of platinum compared to other defect models and other Mo_xN_y phases.

Introduction

Catalyst support durability is currently a technical barrier for commercialization of proton exchange membrane fuel cells (PEMFCs), especially for transportation applications. Degradation and corrosion of the conventional carbon supports leads to losses in active catalyst surface area and, consequently, reduced performance. As a result, the major aim of this work is to develop support materials that interact strongly with Pt, yet sustain bulk-like catalytic activities with very highly dispersed particles. This latter aspect is key to attaining the 2015 DOE technical targets for platinum group metal (PGM) loadings (0.20 mg/cm^2).

The benefits of the use of carbon-supported catalysts to drastically reduce Pt loadings from the early, conventional Pt-black technology [1–4] are well known. The supported platinum catalyzed membrane approach widely used today for fabrication of MEAs was developed shortly thereafter these early reports [5–7]. Of direct relevance to this present work, are the investigations into Pt particle growth in PEMFCs [8], and subsequent follow-on work showing evidence of Pt particles suspended free of the support within the catalyst layer [9]. Further, durability work has demonstrated the detrimental effects of potential cycling on carbon corrosion [10–14] and the link between electrochemical surface area and particle growth [15].

To avoid the issues with carbon degradation altogether, it has been proposed by numerous fuel cell research groups to replace carbon supports with conductive materials that are ceramic in nature [16, 17, and references therein]. Intrinsically, these many conductive oxides, carbides, and nitrides possess the prerequisite electronic conductivity required, and offer corrosion resistance in PEMFC environments; however, most reports indicate that obtaining sufficient surface area remains a significant barrier to obtaining desirable fuel cell performance. Ceramic materials that exhibit high electrical conductivity and necessary stability under fuel cell conditions must also exhibit high surface area as a necessary adjunct to obtaining high Pt dispersions and Pt utilization targets. Our goal in this work is to identify new synthesis approaches together with

materials that will lead to ceramic supports with high surface areas capable of supporting high Pt dispersions. Several strong candidates for use as PEMFC catalyst supports include: transition metal nitrides and sub-stoichiometric titanium oxides, which hitherto now have been prepared by other research groups with relatively low surface areas (ca. $1\text{--}50 \text{ m}^2/\text{g}$ typical [16–19]).

This report describes our FY 2011 technical progress related to applying advanced synthetic methods towards the development of new ceramic supports for Pt catalysts for PEMFCs.

Approach

Our approach to preparing ceramic powders with prerequisite properties for use as a PEMFC Pt catalyst support is centered on the application of several novel materials synthesis methods. Initially, in this first year of work, the methods were conducted in parallel to insure the best possible results that ceramic support materials would be available with desirable physical characteristics for platinum disposition and subsequent electrochemical characterization for oxygen reduction activity. Following a down-select process, we are employing a materials synthesis process called PAD that was largely developed at LANL for a variety of applications. This is a solution method for the formation of materials ranging from oxides to nitrides and oxynitrides. In general we have employed this methodology to prepare conformal epitaxial films of metal oxides and nitrides. However, high surface area powder materials can also be obtained using an accelerated heating rate to generate low density, foam-like structures. This project is presently driving studies into the application of the PAD technique for bulk powder synthesis. The UNM component of the collaborative research project focuses on developing aerosol synthesis methods for high surface area, conductive ceramic supports. Following a No-Go decision made this year (FY 2011) for conductive Nb-RuO_x oxide supports, their goal will be to develop a new approach for nitride and sub-stoichiometric titania as a potential route to the PAD-prepared nitride supports already identified as encouraging non-carbon supports for PEMFCs in this project to date.

Computational methods will be used to complement the experimental effort. Although these techniques provide insight into fundamental processes occurring at the atomic level, our work will focus primarily in two areas, that of aiding the characterization and understanding of experimental data and providing additional direction to the experimental team in the preparation of new support materials with optimized properties. The theory and modeling work will focus on several areas of importance to the development and optimization of new electrode support materials. Initially, computational studies have been carried out to understand the structure and stability of the support materials in the absence of platinum particles. Following this, the parameters may then be used to study the nature of the platinum binding sites on the support and the platinum

adhesion energy, the mobility of platinum on the support and the interplay between the electronic structure of the support and the platinum particle, which is reflected in the calculated density of states. Comparison of these values with bulk platinum can be used as a predictive tool for the optimization of the material.

Results

Molybdenum Nitride

The use of the PAD process has been successful at producing conductive ceramic materials with high surface areas. A milestone for this task has been accelerated such that the Go/No-Go decision in Q8 may be brought forward to early FY 2011. High surface area, conductive foams were successfully synthesized for molybdenum as Mo_2N . The materials are prepared by first creating a water-based solution of the desired metal bound to a polyethyleneimine (PEI) polymer and ethylenediamine tetraacetic acid (EDTA). The solution is concentrated to a thick gel before being heated in a tube furnace to 700 and 950°C under forming gas. During the heating process, the polymer and the EDTA decomposes to give gaseous products, which aid in foam formation.

During FY 2011, a full electrochemical characterization of the newly synthesized supports was conducted with and without platinum in organic and aqueous solutions in order to study the possible redox reactions of the supports, their possible degradation reactions and electrocatalytic activity for oxygen reduction reaction (ORR). Mo_2N , TiO and TiO_2 show good stability for the length of the experiments conducted in a half cell, and their long-term durability study will be conducted in FY 2012 in a fuel cell.

The electrocatalytic activity of Pt deposited on Mo_2N was studied using electroanalytical techniques such as rotating ring-disk electrode (RRDE) and cyclic voltammetry (CV). Platinum was added (20% wt) to Mo_2N support using an incipient wetness method and deposited on glassy carbon electrode for electrochemical characterization. Figure 1(a) shows the CVs of Pt on Mo_2N and PEI-EDTA supports in deaerated 0.5 M H_2SO_4 solutions. Characteristic Pt redox reactions in acidic medium were observed with both samples including hydrogen adsorption/desorption. The Pt/ Mo_2N catalyst has a redox couple at $E=0.44\text{V}$ vs. reference hydrogen electrode (RHE) that was not observed with the Pt/PEI-EDTA catalyst and thus is attributed to the Mo_2N support and not the carbon precursor used during its synthesis, this is also supported by the results obtain with the support devoid of platinum. The average electrochemically active surface area calculated from the hydrogen adsorption and desorption peaks of the Pt/ Mo_2N catalyst is $120\text{ m}^2/\text{g}$, more than 60% higher than that obtained with a commercial ETEK Pt/C catalysts ($74\text{ m}^2/\text{g}$). Figure 1(b) shows the RRDE measurements conducted with the Pt/ Mo_2N catalyst. These results show the high ORR activity (expected from Pt-based catalysts), the kinetics and mechanism of the reaction

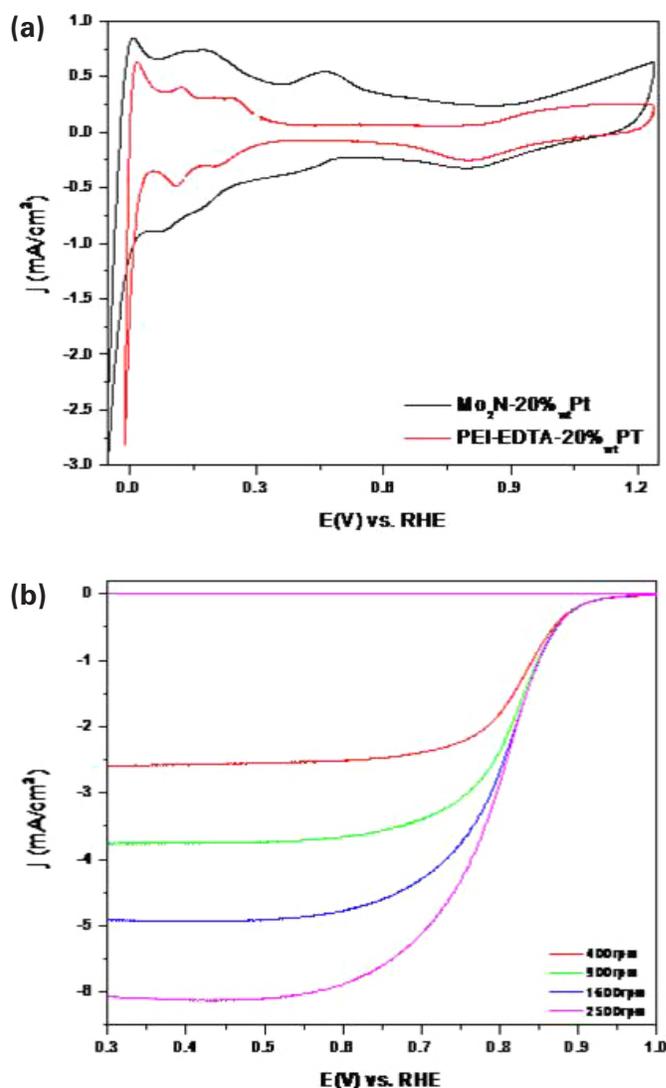

FIGURE 1. (a) CV characterization of 20%_{wt} platinum deposited on Mo_2N sample prepared at 950°C using the PAD process and 20%_{wt} platinum deposited on PEI-EDTA (in deaerated 0.5 M H_2SO_4 at 100 mV/s). (b) RRDE characterization of 20%_{wt} Pt/ Mo_2N sample prepared at 950°C using the PAD process (in O_2 saturated 0.5 M H_2SO_4 at 100 mV/s).

do not seem to be affected from the Mo_2N support or any interaction it might have with Pt.

Sub-Stoichiometric Titanium Oxides

High surface area, conductive foams were successfully synthesized for titanium as both TiO and TiO_{2-n} using a modified PAD process. As with the molybdenum nitride materials, the titanium oxide ceramics are prepared by first creating a water-based solution of the desired metal bound to a PEI polymer and EDTA. The solution is concentrated to a thick gel before being heated in a tube furnace to 950°C under forming gas. During the heating process, the polymer and EDTA decomposes to give gaseous products, which aid

in foam formation. In the case of titanium oxide materials, the variation of the flow rate and purge time determine the extent of oxygen reduction. In FY 2011, effort on the titania supports was reduced in order to provide extra resources to study the moly-nitride materials. However, initial electrochemical characterization was carried out on the two samples produced to date. Figure 2 shows the X-ray diffraction (XRD) traces of a PAD-prepared stoichiometric TiO sample (Figure 2(a)) and sample whose XRD trace shows a primary anatase phase (TiO_{2-x}) along with rutile (Figure 2(b)). Both samples are black in appearance and are conductive. The initial Brunauer-Emmett-Teller (BET) surface area measurements performed on the first samples of black titania powders confirm gas accessible surface areas similar to Vulcan XC-72 (e.g. 200–250 m^2/g). These surface areas are significantly higher than commercial, conductive Magnéli phase Ti_4O_7 synthesized through bulk synthesis and reduction (ca. 1-2 m^2/g) or even through hydrogen reduction of nano-crystalline anatase or rutile TiO_2 powders (ca. 25-50 m^2/g) [16,17]. We have started structural characterization of these recently prepared titania supports. Electrochemical characterization was conducted with Pt deposited on TiO and TiO_2 supports. As with the Mo_2N support, the platinum's ORR activity was not affected by the support in comparison to carbon supported Pt.

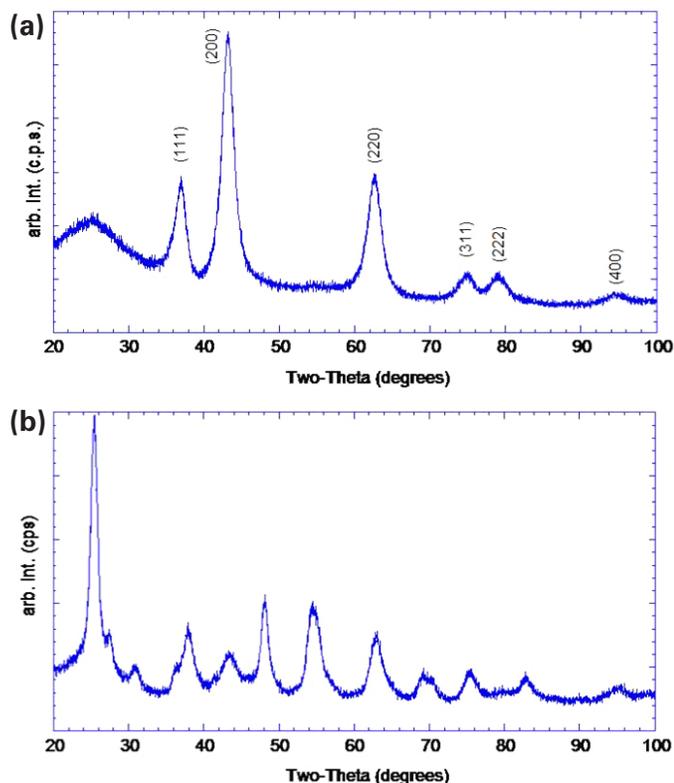

FIGURE 2. (a) XRD trace from 20 to 100° degrees two-theta of a PAD-prepared stoichiometric TiO sample and (b) a sample whose XRD trace shows a primary anatase phase (TiO_{2-x}) along with rutile.

Quantum Chemical Calculations on Catalyst Surface Structure and Activity

In FY 2011, the theory and modeling work was directed to the study of the structure of the interface between the ceramic support and platinum, and the correlation between this and the resulting catalytic activity. The aim of this work is to understand how the support modifies the electronic structure of the platinum to influence the thermodynamics and kinetics of the fundamental steps in the catalytic process. An important target is the computed binding energy of platinum to the surface and relating this to measured catalytic lifetime.

The modeling focused on the dominant γ - Mo_2N phase identified from the characterization of the synthesized samples. The computational strategy was as follows:

1. Construct structural models for Mo_2N phase considering the effect of non-stoichiometry and defect structures.
2. Calculate binding energies for platinum monolayers on surface models.
3. Calculate trends in predicted over-potential for models.

The quantum chemical calculations are based on the plane wave density functional method as implemented in the VASP software. In Q4, we will transition this approach to the study of titanium oxide phases.

The structure of γ - Mo_2N phase is based on the rock salt crystal structure with half the nitrogen sites vacant. There are several models that can be constructed based on this stoichiometry. For example, the highest symmetry model has planes of nitrogen atoms empty as shown in Figure 3(a). This results in the creation of nitrogen-rich and nitrogen-poor surfaces. The binding energies of single platinum atoms on several surface models were calculated. The results for the three sites on a nitrogen-poor γ - Mo_2N surface are shown in Figure 3(b). The results indicate the four-fold coordination site is dominant. Using this result models for a single monolayer of platinum on the ceramic surface were constructed. It is found that the monolayer is bound more strongly to the nitrogen-poor (defective) surface than to the nitrogen-rich (non-defective) surface. This causes a shift in the calculated d-band center for platinum and perturbs the binding energies of intermediates in the oxygen reduction reaction.

UNM Development Work on Conductive Oxide Supports

Mesoporous Nb_2O_5 and NbRu_yO_z (12 wt%) powders were synthesized by aerosol pyrolysis of alcohol solutions of NbCl_5 , RuCl_3 with the addition of pluronic block copolymer P123 as a templating agent. A post acid etch step opened up the internal surface of the as-prepared material yielding a BET surface area as large as 180 m^2/g . Electrical resistance of the compacted powders was assessed and NbRu_yO_z reduced under a 10% H_2/N_2

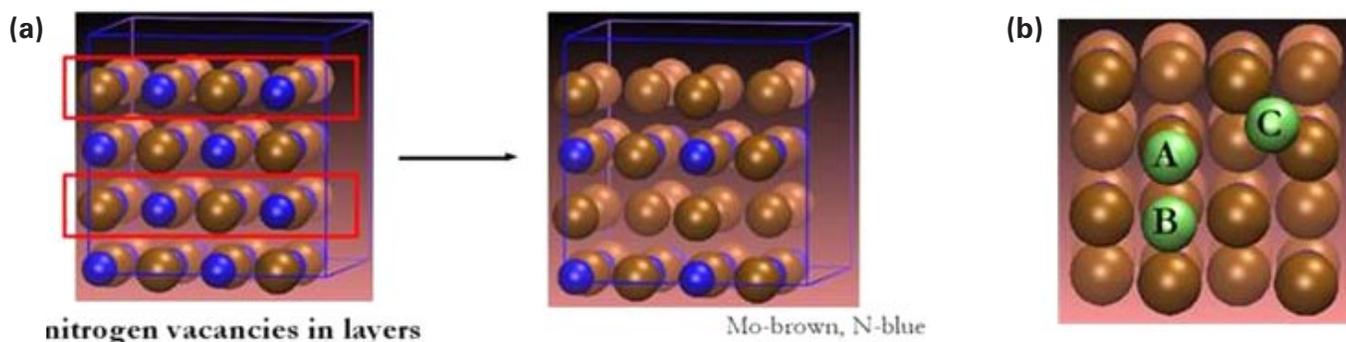

FIGURE 3. (a) Construction of the high symmetry defect model for γ - Mo_2N (b) Calculated binding sites for a single platinum atom on the nitrogen-poor γ - Mo_2N surface (A=on-top, B=bridge, C=four-fold sites)

mixture displayed low resistivity. An optimized synthesis and post-processing scheme was identified producing a black catalyst support. Platinized catalysts were prepared both in situ to the aerosol process and using an incipient wetness approach with the former, direct incorporation of Pt producing better dispersion of Pt nano-particles in the meso-porous support as revealed by transmission electron microscopy (TEM). CV (10 mV/s in 0.1M HClO_4) was performed on NbRu_yO_z supported Pt catalysts 30 wt% Pt) and compared to 30 wt% Pt/XC-72 carbon. These results showed low electrochemical activity and after considerable investigation, it was found that the low activity may be attributed to the formation of NbO_x passivation layer over the Pt nano-particles. It was found that controlled thermal treatment (crystallization) reduced the mobility of Nb and improved the electrochemical performance but still resulted in performance well below commercial Pt/C benchmarks. As a result of these findings, a NoGo decision was made and a Go/No-Go milestone was advanced in the project. Given the favorable results to date for the nitride and titania supports, future work for UNM will focus on aerosol synthesis of high surface area powders without the residual carbon contamination resulting from the PAD process.

Conclusions

- Thermal gravimetric analysis-mass spectrometer (TGA/MS) experiments performed on $\text{Mo}_2\text{N}/\text{C}$ and $\text{Pt}/\text{Mo}_2\text{N}/\text{C}$ materials showed carbon residue cannot be removed from ceramic supports by methanization (reducing conditions, 6% H_2) or oxidation (air).
- Carbon is present from PAD process and, unless it can be removed during initial pyrolysis step, will be present if the PAD process is used to form high surface area support powders.
 - Measurements indicate variable amount of residue but typical amounts ca. 40-50 wt% C remaining in titania supports determined by energy dispersive X-ray.
 - Precision TGA (oxidizing conditions) will be used to better estimate quantify of carbon residue in

moly-nitride system (assuming stoichiometric gamma phase).

- The effect of carbon residue on durability and fuel cell performance is not yet known.
- $\text{Mo}_2\text{N}-\text{C}$ possesses required surface area and electronic conductivity for fuel cell use.
 - Required stability in acid conditions and under potential cycling.
- 20 wt% $\text{Pt}/\text{Mo}_2\text{N}-\text{C}$ (incipient wetness) has comparable activity for ORR as ETEK.
- Pt appears to be associated with Mo_2N and not the residual carbon and this conclusion is supported by:
 - TGA/MS experiments
 - ORNL TEM characterization
 - CV experiments
- Experimental evidence collected to date indicates a stronger Pt-support interaction than with Pt-C catalysts.
- Computational work identified most favorable binding sites for adhesion of Pt atoms, and a monolayer of Pt was constructed based on these results.
 - The structure of the ceramic surface and, in particular, the defect structure appears to be vital to the binding properties of platinum.
 - The modeling results indicated a nitrogen depleted surface layer promotes strong binding of platinum to the support surface.
- $\text{Mo}_2\text{N}-\text{C}$ although not completely understood, is acceptable to move forward to MEA prep and fuel cell testing.

Future Directions

- Scale up amount of PAD-produced Mo_2N , formulate inks, and prepare MEAs for single cell testing.
- Begin fuel cell testing and lifetime-durability observations with $\text{Pt}/\text{Mo}_2\text{N}-\text{C}$ system. Optimize inks and MEA fabrication based on $\text{Pt}/\text{Mo}_2\text{N}$ catalysts and prepare single-cell fuel cell for performance and

- durability testing. Obtain fuel cell performance data for Pt/Mo₂N catalyst prepared using the PAD approach.
- Resume sub-oxide titania support work with focus on half-cell durability, oxidation resistance (sub-oxides), and stability of carbonaceous PAD residue (TiO₂).
 - Develop aerosol precursors and aerosol synthesis method to prepare high surface area (>200 m²/g) Mo₂N catalyst supports with reduction in residual carbon compared the PAD approach (UNM).
 - Calculate the over-potential for the oxygen reduction reaction on a model for platinum supported on molybdenum nitride and compare this value with that for Pt (111).
 - Characterization and testing of support materials (ongoing through entire project).

Project Start Date: January, 2007
 Project End Date: September, 2011²

Fiscal Year (FY) 2011 Objectives

Develop new classes of alternative support materials that meet the 2010 DOE performance targets by achieving the following specific objectives:

- Understand structural and compositional requirements of conductive metal oxides (CMO) for improved activity and durability over standard Pt/Vulcan XC-72.
- Demonstrate durability and performance advantages of alternative cathode supports such as carbon nanotubes (CNTs), ordered graphitic mesoporous carbon (OGMC), graphene and graphitized carbon nanotubes (GCNT).
- Demonstrate durability and performance of non-carbon CMO supports such as tin-doped indium oxide (ITO).

Technical Barriers

This project addresses the following technical barriers from Fuel Cells section (3.4) of the Fuel Cell Technologies Program Multi-Year Research for Fuel Cells, Development and Demonstration Plan:

- (A) Durability (of Cathode Catalyst Supports)
- (C) Performance (of Supported Cathode Catalyst)

Technical Targets

This project is directed at conducting durability and activity studies of Pt on various supports, with the objective of meeting the DOE lifetime criteria.

Membrane electrode assembly (MEA) tests are in progress for lead supports using CMO modification of novel carbon supports, and have shown 3-4X improvement in stability over baseline Vulcan XC-72 carbon supports (Table 1). Rotating disc electrode (RDE) tests have also shown significant improvement in durability over baseline. Optimization of GCNT diameter and CMO content are further expected to improve performance and durability.

TABLE 1. Progress towards Meeting Technical Targets for Electrocatalysts for Transportation Applications

Parameter	Units	2010 Stack Target	PNNL 2011 Status
Accelerated test loss, 200 h @ 1.2 V at 80°C	mV at rated power	< 30	3-4X improvement over baseline for MEA
	% electrochemical surface area (ESA) loss	< 40	3-4X improvement for RDE and MEA tests
Durability with cycling at 80°C	Hours	5,000	To be determined

FY 2011 Accomplishments

- Determined optimum GCNT diameter for best performance and durability.
- Used lessons learned from ITO-graphene systems to develop highly stable ITO-modified GCNT with 4X stability of baseline Vulcan carbon support.
- Demonstrated electronic percolation through CMO-modified carbon support³ and identified need for improving conductivity of non-carbon support by conductivity measurement.
- Improved non-carbon support performance without compromising durability by adding CNT after Pt-CMO synthesis.
- Improved ESA for non-carbon support by tailoring mesoporosity and particle size using hard template synthesis.

¹ Through end of FY 2010

² Work will continue through March 2012

³ Also referred to as hybrid support

- Synthesized non-carbon support using solvothermal annealing method with favorable particle size and crystallinity.

Introduction

Conventional cathode catalyst supports are susceptible to corrosion during high potential excursions, high temperature and under start-stop conditions [1]. Hence, lack of cathode support durability is a major technical barrier with respect to commercialization of fuel cells for transportation [2]. Oxidation of support leads to detachment of Pt from support, while repeated oxidation and reduction of catalyst leads to dissolution and reprecipitation [3]. The dissolution of platinum is accompanied by penetration of Pt into the membrane or gas diffusion layer, while reprecipitation leads to agglomeration of Pt in the catalyst layer. These lead to an overall decrease in ESA along with non-uniform current density distribution, leading to sintering of Pt catalysts caused by localized heating.

In order to overcome these barriers and meet the DOE technical targets for durability and performance, we have developed new classes of alternative and durable cathode supports, based on modifying the carbon surface by conductive metal oxides [4] such as tin-doped ITO, TiO₂ and SnO₂. Alternate supports such as CNT, graphene sheets, OGMC and GCNT were also investigated to take advantage of their superior properties [5-7]. In addition, conductive metal oxides were also used as an alternative to carbon-based supports. The durability and performance have been enhanced due to the following advantages for our cathode supports [8]:

- Thermodynamic stability of Pt-CMO-carbon triple junction, as shown by periodic density functional theory (DFT) calculations, prevents Pt agglomeration.
- Preference of metal oxide nanoparticles to stay at the carbon defect sites lowers carbon corrosion.
- More uniform dispersion of Pt, allowing better performance at equivalent loading.
- Direct contact of Pt with carbon allows use of low cost conductive and non-conductive stable oxides.
- Higher durability of CNT, OGMC and GCNT over Vulcan XC-72 carbon baseline provides potential for an order of magnitude improvement over baseline in durability with metal oxide modification.
- Carbon free metal oxides (ITO) with tailored conductivity and mesoporosity show positive trend in terms of activity and performance.

Approach

New classes of carbon supports modified by CMOs have been developed to improve durability and performance of

the cathode catalysts. In order to prevent alloy formation, electrocatalysts were synthesized by the chemical reduction method using ethylene glycol [9]. Durability of various carbon supports such as Vulcan XC-72 carbon, multiwalled CNT (referred to as CNT in this report), GCNT, OGMC and graphene were compared. DFT calculations performed in FY 2010 on Pt-ITO-graphene were leveraged to study benefits of CMO-modified GCNT support. Conductivity studies were performed on hybrid support Nafion[®] layers to verify electronic percolating through the catalyst layer. Measurements were also done with ITO/Nafion[®] layers to explore pathways for improvement of performance.

Non-carbon support synthesis was modified to reflect the need for higher conductivity and higher triple phase boundary length. In FY 2010, for CMO supports, a doubling in performance with no loss in stability was obtained using cetyl trimethyl ammonium bromide (CTAB) surfactant assisted CMO synthesis. In FY 2011, in order to improve electronic conductivity and tailor particle crystallinity and mesoporosity, both hard template and solvothermal annealing methods were used to synthesize ITO support.

As described in earlier reports, the durability was investigated ex situ using an internally developed accelerated test protocol, with voltage stepped from 1.4-0.85 V vs. normal hydrogen electrode (NHE). An investigation of the effect of CMO modification of GCNT was conducted. MEA tests were performed on various supports with and without metal oxide modification, with the fuel cell held at 1.2 V at 80°C, and measurement of ESA, oxygen reduction reaction activity at 0.9 V and polarization curves performed every 20 hours.

Results

DFT calculations in FY 2010 predicted a stable Pt/CMO/graphene interface, with Pt nanoparticles in contact with both CMO and graphene, followed by verification from transmission electron microscope (TEM) images. Durability for CNT supported catalysts was found to be >2X of baseline in FY 2010. In FY 2011, ITO-modified GCNT was found to have 3-4X higher durability than baseline. Optimization of GCNT diameter has also been carried out. With the current ITO synthesis method, 10-20 and 20-30 nm GCNT provided high ESA, with a significant drop for GCNT supported catalyst of >50 nm. The durability was also adversely affected with increasing GCNT diameter, possibly due to poor coverage of GCNT with ITO. ITO synthesis procedure is currently being modified to provide better coverage on GCNT to further improve both the performance and durability.

In FY 2010, significant improvement in ESA for CMO-supported catalysts was obtained using CTAB assisted synthesis that dispersed ITO precursor more uniformly, with a doubling of ESA to 40 m²/g. Addition of conductive CNT to the synthesized Pt/CNT improved performance without compromising durability, with ESA increasing

to 60 m²/g. Using hard template synthesis, the ESA was increased further by another 10% from 40 to 45 m²/g. Tests are ongoing to determine ex situ durability, followed by in situ assessment of performance and durability. Synthesis of mesoporous ITO using solvothermal annealing is currently ongoing to further optimize ITO mesoporosity and conductivity.

The lead cathode catalysts are shown in Figure 1, with Pt/Vulcan XC-72 as the baseline. CTAB assisted synthesis of Pt/ITO showed doubling of ESA to 85% of baseline value, while its durability was 2-3X that of baseline. Addition of electronically percolative CNT after Pt/ITO synthesis improved the ESA to 20% higher than baseline, while durability was still 2-2.5X higher. Modification of GCNT surface with ITO resulted in better distribution of Pt nanoparticles, resulting in 40% increase in ESA and 35% improved durability over non-ITO modified GCNT support. Based on these results, these compositions were selected for in situ MEA testing.

In FY 2011, ITO modification of GCNT was carried out to improve durability and performance. The optimum ITO content was determined to be 30 wt% as shown in Figure 2. This was complemented by conductivity studies on ITO-carbon composite layers in Nafion[®] that showed that just 30 wt% carbon is sufficient for electronic

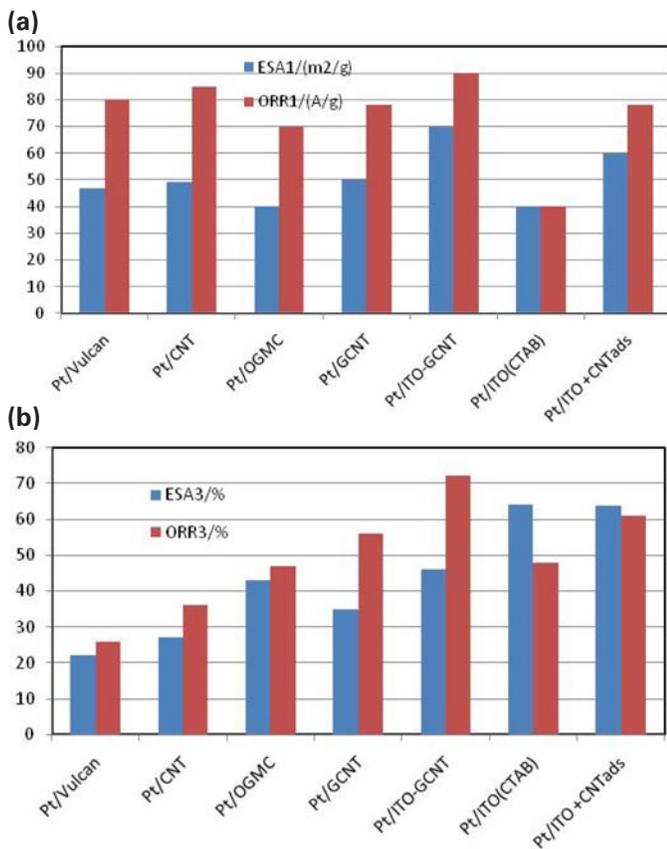

FIGURE 1. ESA (a) and Durability (b) for Lead Cathode Catalysts - RDE Potential Step between 0.85 V (30 sec) to 1.4 V (150 sec) vs. NHE

percolation. Use of this ITO content on GCNT with different diameter showed that activity decreased for >20 nm GCNT, while activity and ESA decreased for >50 nm GCNT (Figure 3). While retention of ESA was the same for all three diameters, the durability in terms of activity retention dropped for GCNT diameter >20 nm. These results show that GCNT support of 10-20 nm was optimum for in situ testing. Efforts are underway to functionalize GCNT to facilitate more uniform ITO deposition and more uniform dispersion of ITO precursor during synthesis. This involved functionalizing with sulfuric and nitric acid to take advantage of the positively charged ITO precursors, and use of polyelectrolytes to enhance ITO precursor dispersion.

MEA tests were conducted on select catalysts, with degradation done by potential hold at 1.2 V at 80°C/7.4 psig/100 % relative humidity, followed by

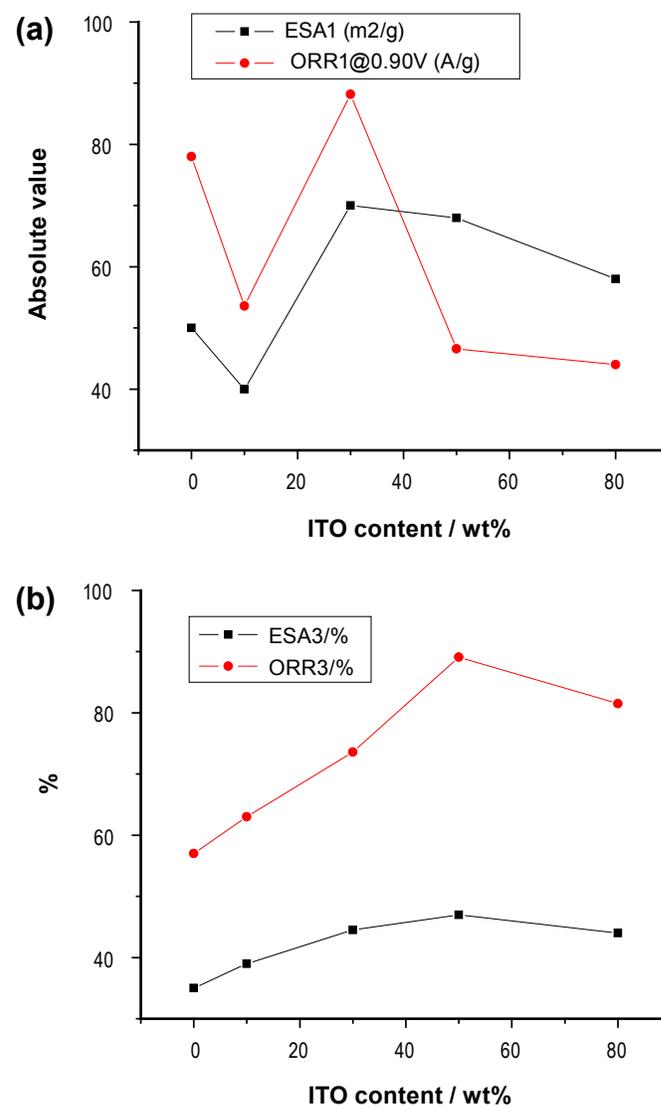

FIGURE 2. Optimization of ITO Content in ITO-GCNT (a) ESA/Activity, (b) Durability

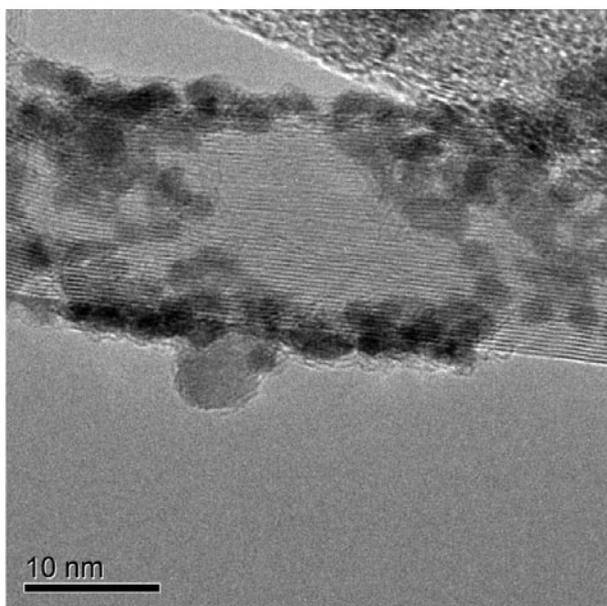

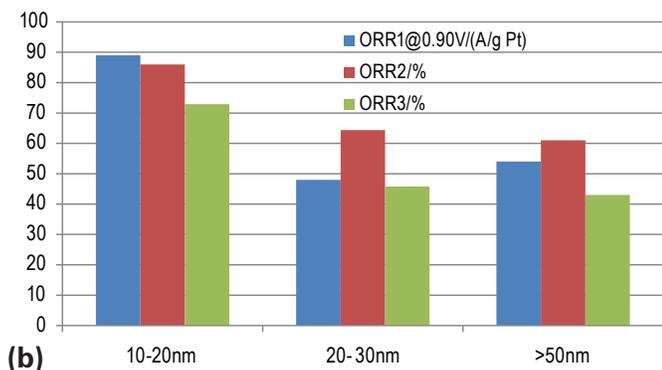

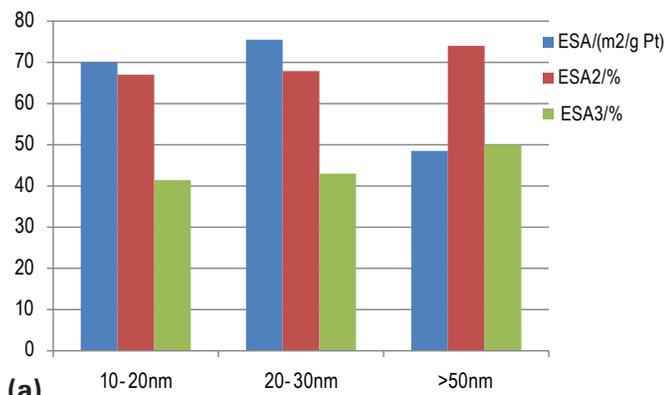

FIGURE 3. Optimization of GCNT Diameter for ITO Modification of GCNT (a) ESA and ESA Retention after 20 and 40 hours (b) Activity and Activity Retention (c) TEM for Optimized Pt/ITO-GCNT for Optimized 10-20 nm dia GCNT

measurement of ESA, activity and polarization curves. In FY 2010, significantly higher durability was achieved for Pt/CNT and slightly higher durability for Pt/OGMC compared to baseline both in terms of ESA degradation.

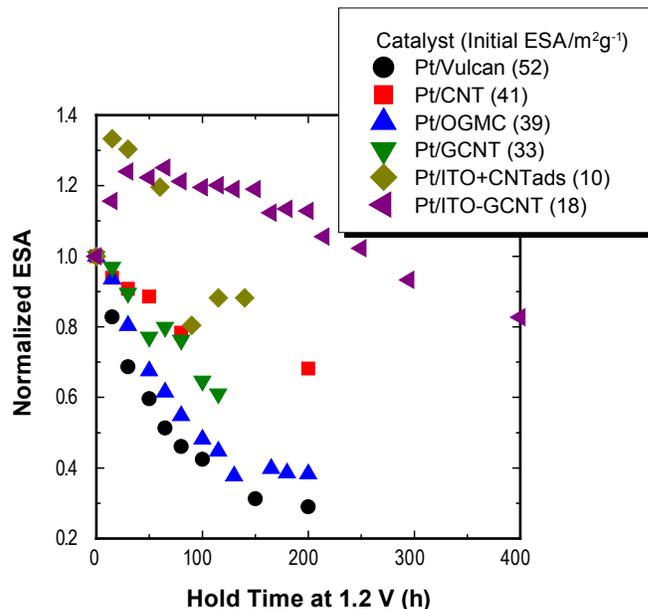

FIGURE 4. MEA Durability Results for Lead Supports (Initial ESA in brackets.)

Figure 4 shows the in situ durability for Pt-supported ITO-modified GCNT, compared with GCNT and baseline supports, with initial ESA provided. While the baseline supported catalyst lost 70% of its ESA in 50 hours and the GCNT supported catalysts lost 40% in 120 hours, Pt/ITO-GCNT lost only 20% of its ESA after 400 hours, thus making it >3-4X more stable than the baseline.

For non-carbon supports, while Pt/ITO was quite stable, its in situ ESA and performance was quite poor (2 m²/g). Conductivity tests on ITO/Nafion[®] layer showed an insulating characteristic for this layer. Hence about 20 wt% CNT was added to Pt/ITO in order to increase electron percolation. This resulted in an increase of ESA to 10 m²/g, with 3X durability of baseline (Figure 4). As seen in Figure 1, the ex situ durability was also 3X that of baseline, while ESA had tripled to 60 m²/g over Pt/ITO (data for Pt/ITO not shown).

While in situ tests showed better durability than baseline for non-carbon supports, efforts are ongoing to improve activity and ESA. In order to improve the electronic conductivity of ITO while also increasing the triple phase boundary length, solvothermal annealing and hard template synthesis of ITO was carried out to tailor mesoporosity and conductivity. The ESA had increased to 45 m²/g for ITO synthesized by the hard template method. X-ray diffraction and Brunauer-Emmett-Teller measurements showed that the particle size was around 20 nm, with pore size in the 8-10 nm range. Figure 5 shows TEM images of Pt/ITO synthesized by the above methods. Conductivity measurements on this sample will be carried out prior to in situ testing.

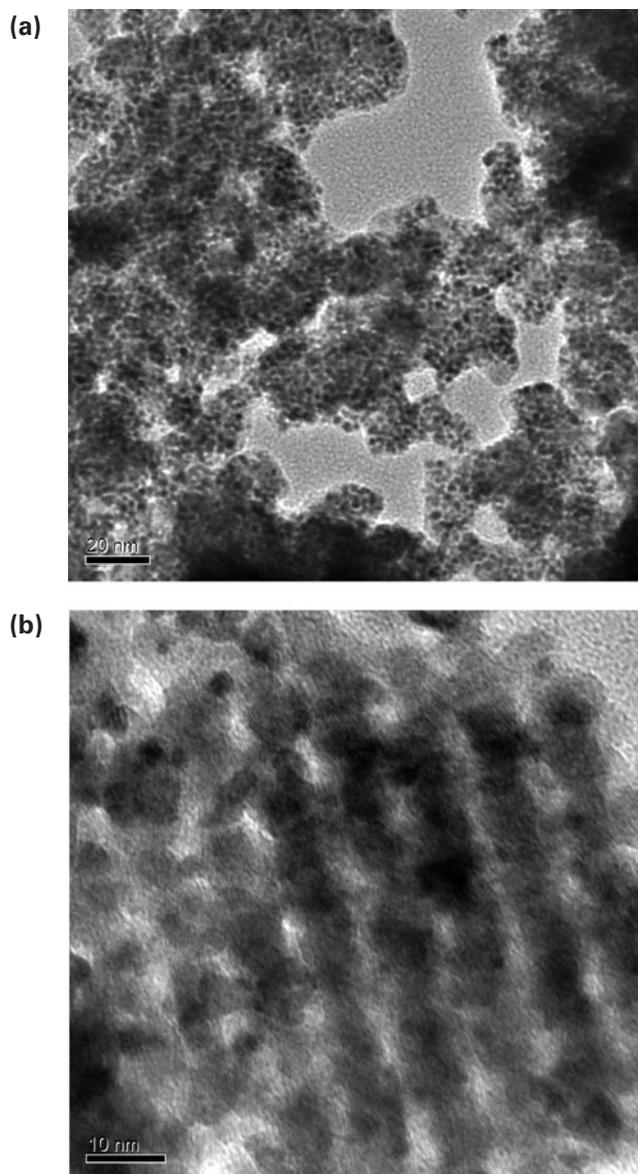

FIGURE 5. Pt/ITO (a) CTAB-Assisted (b) Hard Template Method – Evidence of Mesoporosity for the Hard Template Method

Conclusions and Future Directions

Significant progress has been made in improving supported cathode performance and durability:

- Optimum ITO content in the ITO-GCNT was found to maximize activity and durability.
- Optimum GCNT diameter was determined to maximize performance and durability of ITO-graphene supports.
- Demonstrated >3-4X stability of Pt/ITO-GCNT over baseline Pt/Vulcan carbon.
- Demonstrated 3X durability of Pt/ITO over baseline with improved performance by CNT addition.
- Synthesized non-carbon ITO support with desired mesoporosity and conductivity.

Future work will involve improving the performance of non-carbon CMO supports by incorporating mesoporosity within the supports using hard template and solvothermal annealing approach and improving MEA formulation for these novel supports. ITO deposition on GCNT will be optimized to increase uniformity of coverage by modification of GCNT surface properties and increasing the dispersion of ITO precursors. Electrode architecture optimization will be performed by controlling the Nafion® content, catalyst layer thickness, Pt content, layer porosity and pore size distribution. Accelerated test protocol that increases throughput by 3-6X will also be developed.

Project Start Date: October 1, 2009
Project End Date: September 30, 2012

Fiscal Year (FY) 2011 Objectives

- Understand the role of cathode electrocatalyst degradation in the long-term loss of polymer electrolyte membrane fuel cell (PEMFC) performance.
- Establish dominant catalyst and electrode degradation mechanisms.
- Identify key properties of catalysts and catalyst supports that influence and determine their degradation rates.
- Quantify the effect of cell operating conditions, load profiles, and type of electrocatalyst on the performance degradation.
- Determine operating conditions and catalyst types/structures that will mitigate performance loss and allow PEMFC systems to achieve the DOE lifetime targets.

Technical Barriers

This project addresses the following technical barriers from the Fuel Cells section of the Fuel Cell Technologies

Program Multi-Year Research, Development and Demonstration Plan:

- (A) Durability
- (B) Cost
- (C) Performance

Technical Targets

This project is conducting fundamental studies of platinum-based PEMFC cathode electrocatalyst degradation mechanisms. Insights gained from these studies can be applied toward the definition of operating conditions to extend PEMFC lifetimes and to the development of cathode electrocatalyst materials that meet the following DOE 2015 electrocatalyst durability targets with voltage cycling:

- 5,000 hours (<80°C) and 5,000 hours (>80°C).
- <40% loss of initial catalytic mass activity after 30,000 cycles between 0.6 and 1.0 V.
- <30 mV loss at 0.8 A/cm² after 30,000 cycles between 0.6 and 1.0 V.

FY 2011 Accomplishments

- Completed parametric and particle size studies comparing membrane electrode assembly (MEA) performance degradation for Pt₃Co and Pt cathodes with similar initial particle sizes.
- Determined that voltage cycling from 0.6 to 1.0 V causes Pt particles of <~7 nm to grow to ~9.5 nm, irrespective of initial particle size, with evidence for both dissolution and coalescence growth mechanisms.
- Determined that Pt dissolution increases with decreasing Pt particle size and is correlated with oxide formation.
- Developed Pt cyclic voltammetry and dissolution models and Kinetic Monte Carlo (KMC) model of alloy nanoparticle dissolution for defining the alloy nanoparticle parting limit.

Introduction

One of the primary challenges facing the development of PEMFCs for automotive and stationary power applications is the durability of the fuel cell materials. The observed performance degradation has reversible and irreversible components. The topic of this project is the irreversible degradation of Pt-based cathode catalysts,

because the degradation of this component has the most profound impact on cell performance. The project's primary focus is elucidation of the effects of catalyst and support physicochemical properties and cell operating conditions on the rates and mechanisms of cathode catalyst degradation, with a secondary focus on the impact of catalyst degradation on the transport properties of the cathode. The results of this project will define the operating conditions and catalyst types/structures that will mitigate performance loss and allow PEMFC systems to achieve the DOE lifetime targets.

Approach

The project approach is to perform: (1) systematic cell degradation tests, (2) in situ and ex situ structural characterization of the catalysts, (3) fundamental out-of-cell studies, and (4) theoretical modeling to identify the degradation modes and factors contributing to cathode catalyst degradation. The catalysts studied are benchmark Pt on carbon supports with varying properties, Pt alloys with varying oxophilicity, and three classes of Pt catalysts having the highest reported oxygen reduction activity. Specifically, our approach is to utilize accelerated stress tests of MEAs containing various catalysts and supports and in situ and ex situ dissolution, microscopic, structural, and chemical characterization of these catalysts. To elucidate the effect of particle size, we are systematically varying the particle size of Pt and one Pt alloy (Pt₃Co) on a standard support. To elucidate the effect of catalyst type and catalyst oxophilicity, we are studying four classes of catalysts: Pt, Pt alloys, acid-leached alloys, and core-shell catalysts while either controlling or carefully determining the particle size and particle size distributions. To elucidate support effects, we are studying Pt on carbon supports with varied surface area, pore size, and relative proportions of micro- and mesopores. We are also determining the effects of a catalyst precursor impurity on degradation rates by post-synthesis doping of a Pt/C catalyst with varying levels of a precursor impurity (e.g., Cl).

The results of the experimental efforts feed into coupled models at various levels of complexity from atomic-level, *ab initio* oxidation and dissolution calculations, to catalyst degradation models, to cell kinetic and transport models. The modeling effort also defines the experiments necessary to complete the cell model. The project can be categorized into three broad and coupled tasks: (1) MEA studies utilizing accelerated stress test protocols, on-line electrochemical diagnostics, and post-test microscopic and X-ray scattering characterization, (2) mechanistic and physicochemical property studies using aqueous electrochemistry, X-ray spectroscopy/scattering, transmission electron microscopy (TEM), scanning transmission electron microscopy (STEM), in situ TEM, and quartz crystal microbalance measurements, and (3) model development, verification, and implementation. All of these techniques have been demonstrated to provide important and complementary information regarding catalyst degradation mechanisms.

Results

The focus of this year's effort has been on parametric and particle size studies of MEAs with Pt₃Co cathode electrocatalysts, comparison with identical studies of Pt MEAs, electron microprobe (EMPA) and STEM analysis of cycled Pt MEAs, degradation mechanism experiments and modeling of Pt cathode catalysts, and *ab initio*-based modeling of Pt-Co alloys. Catalysts were prepared containing 40 wt% Pt₃Co nanoparticles with a mean diameter of 5.6 nm on high-surface-area Ketjen black carbon support (Pt₃Co/C). This material was heat treated to form catalysts with mean particle sizes of 8.7 and 14.3 nm. These catalysts were also incorporated into the cathodes of MEAs and subjected to the DOE cycling protocol (0.6 to 1.0 V, 50 mV/s) in the fuel cell environment. Cell diagnostics of cathode catalyst electrochemically active surface area (ECA), oxygen reduction reaction (ORR) mass activity, and air and oxygen polarization curves were performed after 1,000, 3,000, 5,000, and 10,000 voltage cycles. Studies were also performed on the effect of various fuel cell operating parameters (relative humidity [RH], temperature, cycling profile, and upper potential limit) on the degradation of the cathode electrocatalyst performance with MEAs containing the 5.6 nm Pt₃Co/C. The results of the particle size and parametric studies on the Pt₃Co and comparison with the Pt results shown in last year's report are summarized in the following.

- Increasing the upper limit of voltage cycling increases cathode catalyst surface area and mass activity loss.
- Low inlet relative humidity decreases cathode catalyst degradation.
- ECA loss: Depends on catalyst particle size. No statistically meaningful difference was observed between Pt and Pt₃Co MEAs.
- ORR mass activity loss: Depends on catalyst particle size. The mass activity of Pt₃Co is more stable than the mass activity of Pt (Figure 1).
- Initial performance: Pt₃Co-based MEAs showed better beginning of life performance than Pt-based MEAs (~20 mV in H₂/O₂ or ~15 mV in H₂/Air @ 1 A/cm²).
- Performance degradation: At high currents, the performance loss depends on catalyst particle size, no statistically meaningful difference was observed between Pt and Pt₃Co MEAs (Figure 1).
- The ionic resistance in the electrode is higher for cycled Pt₃Co cells than cycled Pt cells, which offsets the improved mass activity stability of the alloy.

This year's effort in the ex situ characterization tasks included post-cycling EMPA of the Pt₃Co and Pt-containing MEAs and STEM analysis of the Pt-containing MEAs. These MEAs had varying initial Pt particle size (1.9, 3.2, 7.1, and 12.7 nm) and were subjected to the DOE cycling protocol for 10,000 cycles (30,000 for the 7.1 nm particle

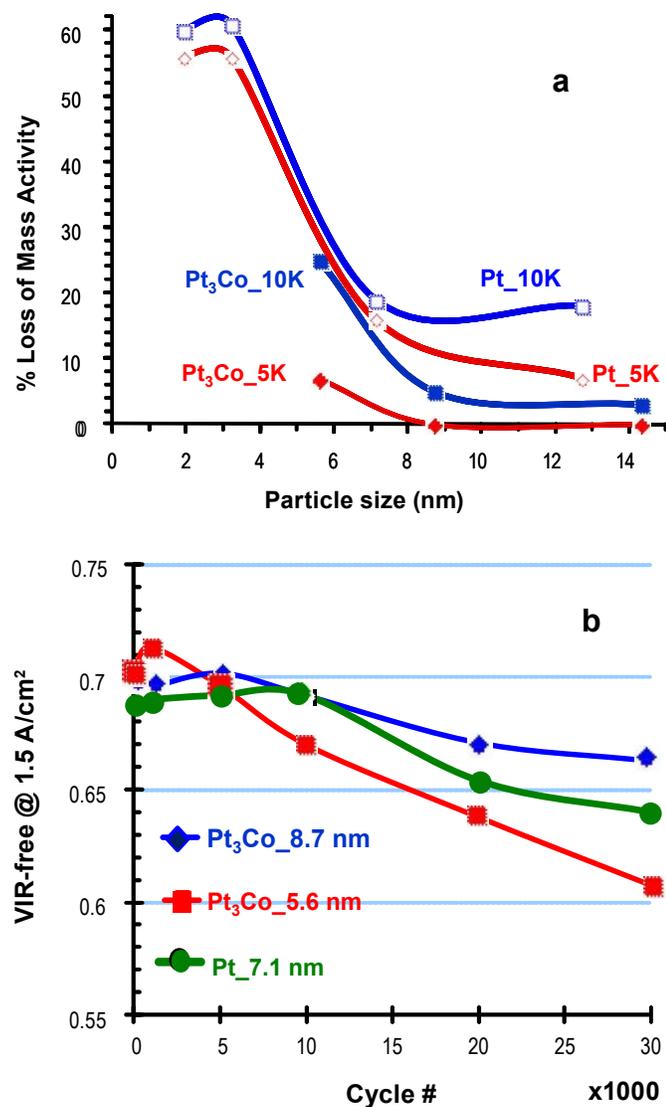

FIGURE 1. (a) Loss of oxygen reduction reaction mass activity after 5,000 (Pt_5K and Pt₃Co_5K) and 10,000 (Pt_10K and Pt₃Co_10K) cycles in an MEA (DOE protocol) as a function of initial mean particle size of Pt and Pt₃Co catalysts and (b) Internal resistance-free cell voltage at 1.5 A/cm² on air as a function of cycling in an MEA for Pt₃Co (5.6 and 8.7 nm) and Pt (7.1 nm).

size). MEAs with the 3.2 nm Pt/C cathode catalyst used in the parametric studies mentioned above were also analyzed.

The EMPA results showed that Pt migrated into the membrane for all of the Pt and Pt₃Co MEAs, with the exception of the cells tested at lower relative humidity (30% vs. 100%) and the cell with the largest Pt particle size (12.7 nm). The trends in Pt migration into the membrane observed were the same for Pt and Pt₃Co MEAs, including:

- Lower Pt content in the membranes with larger catalyst particle sizes.
- Lower Pt content in the membrane for low RH cycled cell.

- Higher Pt content in the membrane for high voltage and high temperature cycled cell.

The Pt MEA (7.1 nm) had a higher Pt content in the membrane than the Pt₃Co MEAs (5.6 nm and 8.7 nm) after 30,000 DOE protocol cycles.

TEM analyses of the Pt MEAs after 30,000 DOE protocol cycles showed that the extent of growth in the mean particle size and size distribution depend on position in electrode, that dendrites were formed, indicative of the dissolution/re-precipitation mechanism of particle growth, and that coalesced particle shapes were formed. The quantification of the extent of each of the two particle growth mechanisms (dissolution/re-precipitation and coalescence) is underway. The three smallest particle sizes (1.9, 3.2, and 7.1 nm) evolve to approximately the same average particle size (9.5 nm) after extended potential cycling. The largest particle size (12.7 nm) showed no loss of ECA, but did show particle growth in the region of the electrode closest to the membrane due to formation of a few very large particles.

The ex situ characterization task also included a study of the 3.2 nm Pt/C in an aqueous electrochemical environment (0.1 M HClO₄ electrolyte) using anomalous small-angle X-ray scattering (ASAXS). This catalyst was subjected to 900 cycles of two potential cycling protocols: the DOE protocol and 0.4 to 1.05 V square waves (0.4 to 1.05 V, 10 s each potential). The Pt subjected to the DOE cycling protocol only grew by 0.09 nm over 900 cycles, whereas the Pt subjected to the square wave cycling grew by 0.33 nm. Analyses of the change in the particle size distributions for these two sets of data (Figure 2) showed that the mechanism for growth of the mean particle size is similar for the two cycling protocols: loss of particles <3.2 nm and >5 nm, accompanied by an increase in the number of particles in the 3.2-5 nm range, differing only in extent for the two cycling protocols. The largest contributor to surface area loss is loss of particles in the 1.5-3.2 nm diameter range. The majority of the change occurred during the first 100 cycles. Analysis of the ASAXS intensities also shows that there is an overall loss of Pt from the electrodes, with the square wave showing higher loss rates.

In the fundamental out-of-cell studies task, the effect of potential and particle size on the steady-state dissolved concentration of Pt was determined for the Pt/C catalysts (1.9, 3.2, 7.1, and 12.7 nm). This was correlated with the extent of Pt oxide formation, as determined by cyclic voltammetry. These studies, illustrated in Figure 3, showed that the:

- Steady-state dissolved Pt concentration increases with decreasing mean particle size.
- Oxide coverage at constant potentials >0.9 V increases with decreasing particle size.
- Dissolved Pt concentration peaks at an oxide coverage of ~1 O/Pt, decreasing with increasing oxide coverage above a monolayer.

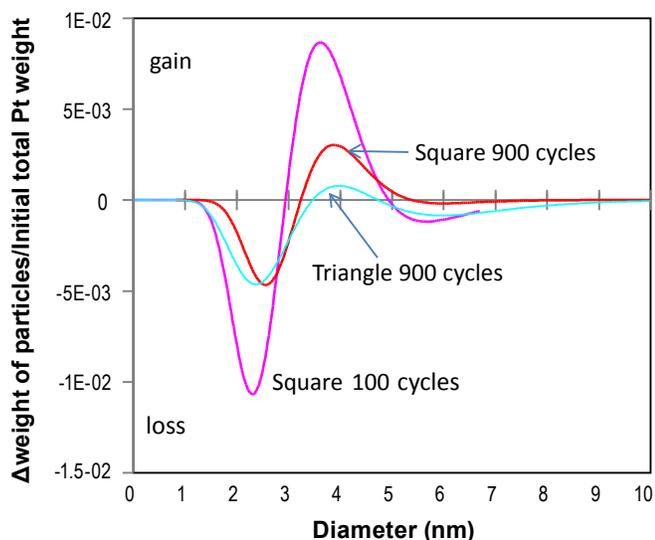

FIGURE 2. Change in the weight of Pt at all particle sizes in the particle size distribution as a result of DOE protocol cycling (0.6 to 1.0 V triangle cycles, 50 mV/s) or square wave cycling (0.4 to 1.05 V, 10 s each potential) in 0.1 M HClO₄ electrolyte. The initial mean particle size of the catalyst was 3.2 nm. Weight changes were derived from ASAXS-determined particle size distributions; spherical nanoparticles were assumed to calculate weights.

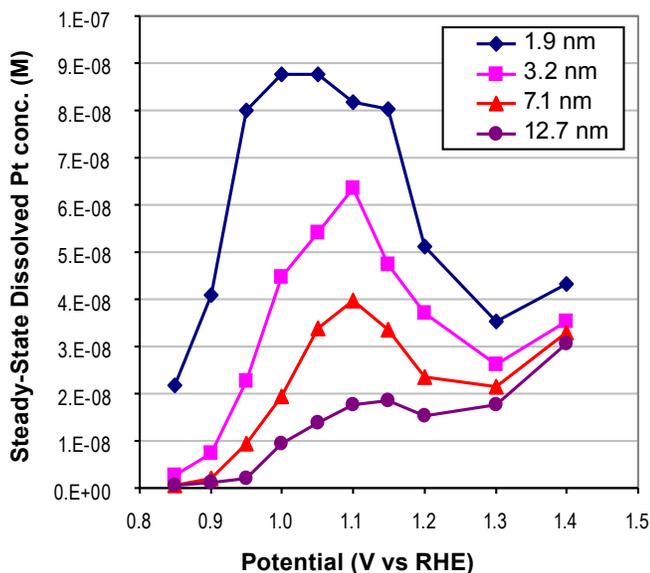

FIGURE 3. Steady-state dissolved Pt concentration in perchloric acid electrolyte as a function of potential for Pt/C of initial mean particle size of 1.9, 3.2, 7.1, and 12.7 nm.

In the theoretical modeling task of the project, a model was developed for Pt cyclic voltammetry and Pt dissolution under steady-state and cycling conditions. A non-ideal solid solution between PtO_x and Pt was assumed where oxide decreases the effective surface activity of Pt. Under steady-state conditions, it was found that: (1) there is a balance

between Pt dissolution and protective oxide formation at >0.8 V, (2) the activity of Pt is strongly dependent on oxide coverage, which is strongly dependent on potential at >0.8 V, and (3) the potential dependence of the dissolved Pt concentration is lower than that expected for a two-electron electrochemical reaction due to non-unit activity of Pt caused by formation of oxide. Under cycling conditions, the kinetic constants for Pt dissolution were determined from potentiostatic concentration-time data at 0.9 V and 72-h equilibrium data for other potentials, the kinetic constants for re-deposition from potential cycling data. Conclusions from this work are: (1) at <0.9 V deposition is competitive with dissolution and (2) at >1 V, cycling accelerates Pt dissolution compared to potentiostatic conditions due to incomplete protection of the oxide.

Also in the modeling aspect of the project, the KMC model developed last year for Pt was extended to include Pt alloys and was applied to the evolution of Pt₃Co nanoparticles under fuel cell conditions. An effective bond-energy Hamiltonian was developed from density functional theory fits, which were then implemented in the KMC model of alloy nanoparticle dissolution. The KMC model predicts rapid Pt_{1-x}Co_x nanoparticle de-alloying at 0.25 < x < 0.5, which suggests that the concentration limit for retaining some Co in the nanoparticle is less than the 0.55 observed for bulk structures (Figure 4).

Conclusions and Future Directions

The following conclusions can be made from our studies of the degradation of Pt₃Co and Pt/C electrocatalysts:

- Initial fuel cell performance increases with decreasing cathode electrocatalyst mean Pt and Pt₃Co particle size, however degradation of performance with potential cycling increases with decreasing particle size.
- Potential cycling (0.6 to 1.0 V; 50 mV/s) causes Pt catalysts of ≤ 7 nm initial mean diameter to evolve to mean particle sizes and specific surface areas of 9.5 nm.
- Performance degradation with potential cycling can be attributed to increased rates and extent of ECA loss with decreasing Pt and Pt₃Co particle size, with ECA loss rates being the same for Pt and Pt₃Co. Despite better ORR mass activity stability than Pt, the Pt₃Co MEAs showed approximately the same performance loss with cycling due to decreased cathode proton conductivity (possibly due to Co²⁺ poisoning of proton-conducting sites in electrode).
- Extent of Pt and Pt₃Co nanoparticle cathode electrocatalyst performance loss, caused by loss of ECA, increases with increasing cell temperature, increasing relative humidity, and increasing upper limit of potential cycling; preliminary analyses indicate a correlation of performance loss with extent of Pt dissolution and loss of Pt from the cathode.

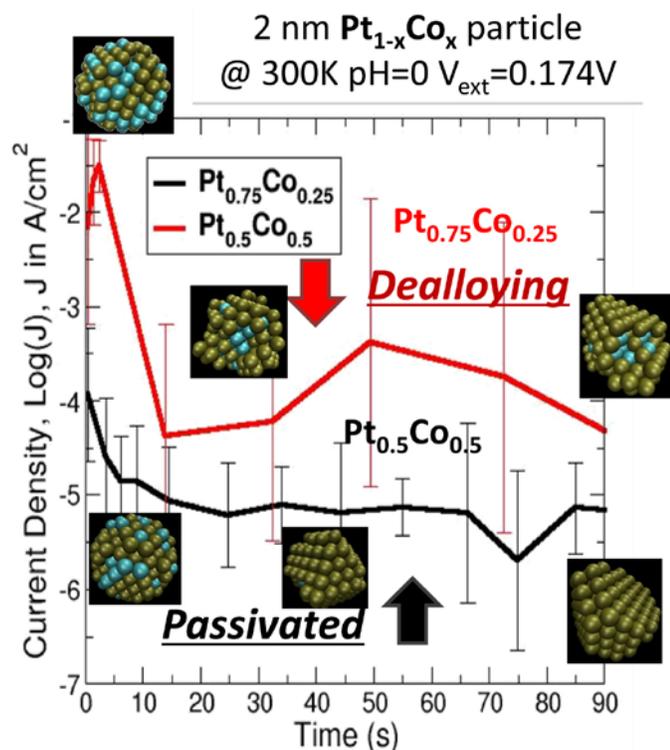

FIGURE 4. Corrosion current density as a function of time for 2 nm $Pt_{0.75}Co_{0.25}$ and $Pt_{0.5}Co_{0.5}$ particles, as derived from Kinetic Monte Carlo calculations. This plot illustrates that $Pt_{0.75}Co_{0.25}$ reaches a stable state, retaining Co in the core, whereas the $Pt_{0.5}Co_{0.5}$ nanoparticle does not passivate before losing all of its Co.

The immediate future direction of the experimental portion of the project is to complete characterization of the Pt_3Co catalysts and cycled MEAs, including acquiring additional data needed for the nanoparticle degradation modeling effort, such as Pt dissolution rates and extent of oxidation as a function of potential. Immediate future work on advanced catalysts will focus on cell fabrication and cycling of MEAs containing Pt_3Sc/C , $PtCo/C$ and $PtCo_3/C$ cathode catalysts.

Near-Term Future Directions

- Characterize Pt dissolution as a function of particle size for Pt_3Co .
- Characterize evolution of Pt_3Co particle size during potential cycling in an MEA using anomalous small-angle X-ray scattering.
- Evaluate the impact of Pt:Co ratio, catalyst leaching, alloying with Sc, alternative carbon support, and impurity doping on degradation.
- Quantify ECA loss due to particle coalescence and Pt dissolution/re-deposition processes by modeling TEM images.
- Complete cyclic voltammetry and dissolution models.

Understand Electrode Structure Impact - Applied Science Subtask

- Better understand the electrode structural and chemical reasons for differences in durability.
- Understand impact of electrode structure on durability and performance.
- Correlate different electrode structures to fuel cell tests and durability.
- Define different fabrication effects (esp. solvents) on electrode structure.

Develop Models Relating Components and Operation to Fuel Cell Durability

- Individual degradation models of individual fuel cell components.
- Development and dissemination of an integrated comprehensive model of cell degradation.

Methods to Mitigate Degradation of Components

- New components/properties, designs, operating conditions.

Technical Barriers

This project addresses the following technical barriers from the Fuel Cells section of the Fuel Cell Technologies Program Multi-Year Research, Development and Demonstration Plan:

- (A) Durability
- (B) Cost

Technical Targets

Transportation Durability: 5,000 hours (with cycling)

- Estimated start/stop cycles: 17,000
- Estimated frozen cycles: 1,650
- Estimated load cycles: 1,200,000

Stationary Durability: 40,000 hours

- Survivability: Stationary -35°C to 40°C
- Cost (\$25/kW_e)

FY 2011 Accomplishments

- Performed all DOE Fuel Cell Tech Team recommended accelerated stress tests (ASTs) on a combination of

Fiscal Year (FY) 2011 Objectives

Identify and Quantify Degradation Mechanisms

- Degradation measurements of components and component interfaces.
- Elucidation of component interactions, interfaces, operation leading to degradation.
- Development of advanced in situ and ex situ characterization techniques.
- Quantify the influence of inter-relational operation between different components.
- Identification and delineation of individual component degradation mechanisms.

materials including ionomers, membranes, catalysts, and catalyst supports.

- Performed neutron imaging determining water profiles to determine effect of carbon corrosion on water management.
- Made durability comparison of electrode layers using Nafion[®] ionomer and a short-side-chained perfluorinated ionomer.
- Performed small angle neutron scattering determining long-range order effect of electrode solvents on electrode durability for ionomer in proton (H⁺) and sodium (Na⁺) forms.
- Measured Nafion[®] crystallinity changes with respect to electrode location.
- Measured component surface species change by X-ray photoelectron spectroscopy.
- Performed characterization of durability in segmented fuel cells.

Introduction

The durability of polymer electrolyte membrane (PEM) fuel cells is a major barrier to the commercialization of these systems for stationary and transportation power applications. Although there has been recent progress in improving durability, further improvements are needed to meet the commercialization targets. Past improvements have largely been made possible because of the fundamental understanding of the underlying degradation mechanisms. By investigating component and cell degradation modes, defining the fundamental degradation mechanisms of components and component interactions, new materials can be designed to improve durability. Various factors have been shown to affect the useful life of PEM fuel cells [1-4]. Other issues arise from component optimization. Operational conditions (such as impurities in either the fuel and oxidant stream), cell environment, temperature (including subfreezing exposure), pressure, current, voltage, etc., or transient versus continuous operation, including start-up and shutdown procedures), represent other factors that can affect cell performance and durability. To achieve a deeper understanding of PEM fuel cell durability and component degradation mechanisms, we have assembled a multi-institutional and multi-disciplinary team with significant experience investigating these phenomena.

Approach

Our approach to understanding durability and degradation mechanisms within fuel cells is structured in three areas: fuel cell testing (life testing, ASTs, ex situ aging), characterization of component properties, and modeling (component aging and integrated degradation modeling).

These areas have aspects that can be considered free-standing, but each benefit greatly from work performed in the other areas. The modeling studies tie together what is learned during component characterization and allow better interpretation of the fuel cell studies. This approach and our team give us the greatest chance to increase the understanding of fuel cell degradation and to develop and employ materials that will overcome durability limitations in fuel cell systems. This work is also being coordinated with other funded projects examining durability through a DOE Durability Working Group, and through a US Fuel Cell Council task force on durability.

Results

Correlating Electrode Structure to Durability

In FY 2010, we demonstrated that the solvents used can have a dramatic effect on the performance durability of the fuel cell electrodes, although the electrochemical surface area (ECSA) of the catalyst was unaffected. Electrodes made from water-based catalytic inks show rapid performance degradation, whereas electrodes made from catalytic inks based on glycerol, show virtually no performance loss. Comparing mass activity and ECSA as a function of particle size normally shows a good correlation [1,5,6]. However, with other types of solvent-produced membrane electrode assemblies (MEAs), the correlation can be poor, or even non-existent. To define the effect of different solvents on the electrode structure performance and durability we conducted small angle neutron scattering (SANS) of both different electrode solvents and Nafion[®] in both H⁺ and Na⁺ form. The SANS for water/isopropanol is shown in Figure 1a and for glycerol in Figure 1b. A peak at a scattering intensity (Q) of ~ 0.04 indicates that the water/iso-propanol mixture shows more long-ranged order than does the glycerol/Nafion[®] mixture. Electrode mechanical strength measurements also suggest that glycerol-cast film shows better mechanical properties than water/isopropyl alcohol-cast films, suggesting that aggregation leads to lower mechanical properties and lower electrode durability.

The durability of electrodes formed with Nafion[®] ionomer was compared to similar electrodes made from Aquivion ionomer, which is ionomer with short-side chains with sulfonic acid. The comparison of the polarization performance during potential cycling ASTs is shown in Figure 2. The MEA using Aquivion ionomer at the cathode showed better stability than the MEA using Nafion[®] ionomer after 30K potential cycling test. The durability of these electrode structures show a similar disconnect between ECSA and performance for Pt/C reinforced as do electrodes made with the different solvents. Note that a reduction in ionomer content compared with MEAs made with Nafion[®] allowed for best performance without loss in potential cycling durability.

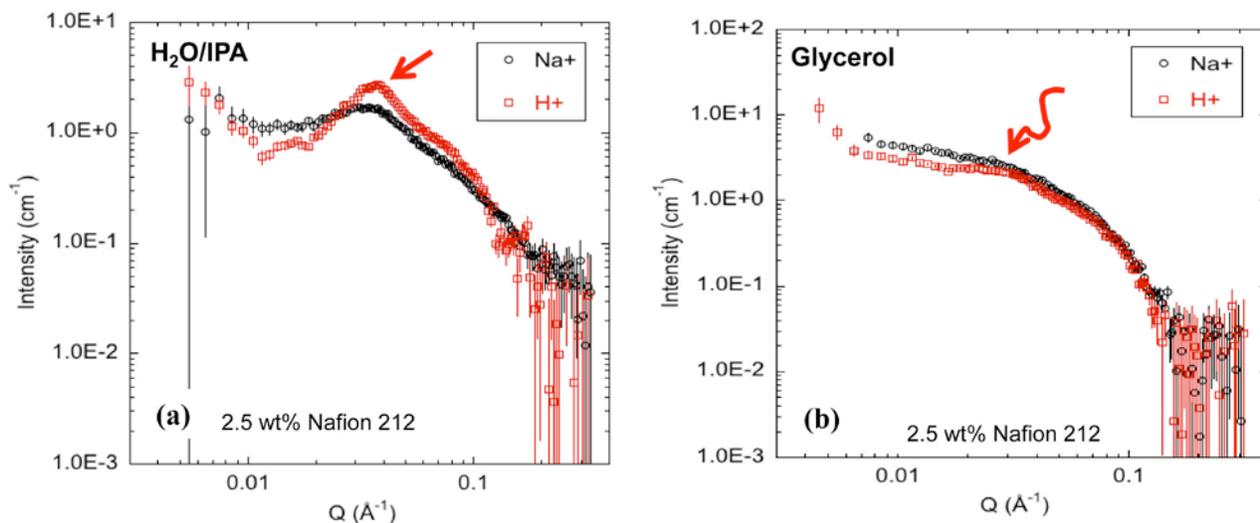

FIGURE 1. SANS of Nafion[®] dispersions with (a) water and iso-propanol as solvent and (b) glycerol solvent. Arrows identify location of SANS peak.

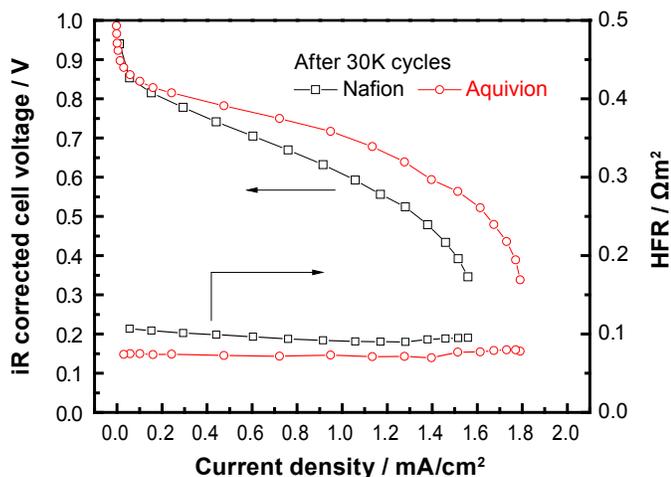

FIGURE 2. Polarization performance after 30,000 potential cycles of Nafion[®] and Aquivion electrodes. Catalyst, GDLs and membranes all identical.

Membrane Crystallinity Measurements

We previously have noted that the crystallinity of Nafion[®] during operation changes. To further investigate this phenomenon, we measured the conducted transmission electron microscopy (TEM) of fresh and AST-tested membranes. In fresh MEAs, small F-rich clusters are observed throughout the thickness of the membrane (from cathode to anode), see Figure 3a. Features exhibit some crystalline nature but are not highly crystallized nor have well-defined surfaces. After open-circuit voltage (OCV)-aging, these small F-rich clusters exhibited increased crystallinity on the cathode side without increasing in size (Figure 3b). The changes in Nafion[®] crystallinity were much more severe on the anode side of the membrane (Figure 3c).

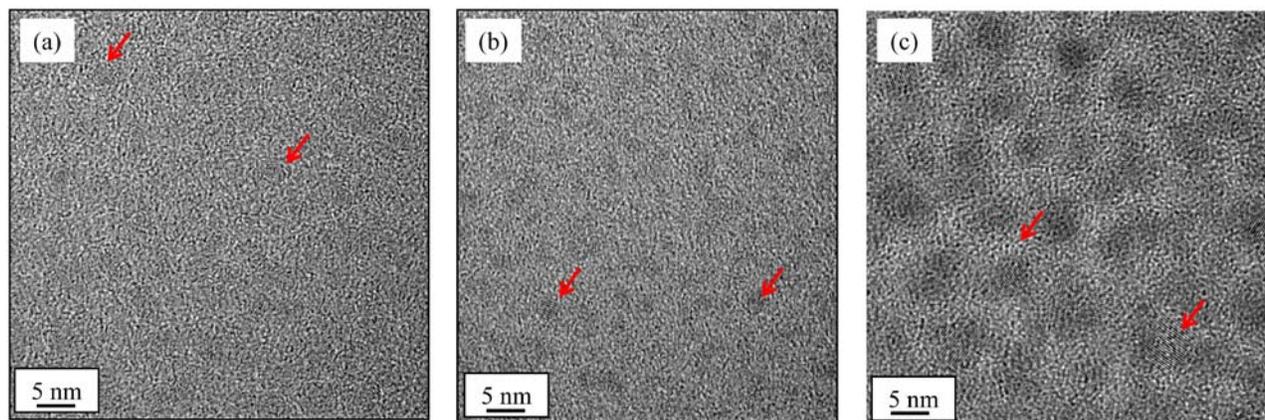

FIGURE 3. TEM of Nafion[®] membrane (a) fresh MEA membrane next to the cathode, (b) OCV-aged MEA membrane next to cathode and (c) OCV-aged MEA membrane next to anode. Arrows show fluorine-rich crystallites.

Durability Effects of Carbon Corrosion

To measure the effect of carbon corrosion on changes in catalyst and microporous layer hydrophobicity, the interaction of heat generation, and water retention in corroded PEM fuel cells, neutron imaging of water profiles was measured during carbon corrosion ASTs. Because of the importance of water content in determining corrosion rates, simultaneous high-resolution neutron imaging of the cells was used to calculate through-plane water profiles during the AST series. Polarization curves for a cell with 24BC cathode and anode gas diffusion layer (GDL) are shown in Figure 4a, taken after consecutive cathode holds at +1.3 V (vs. H₂ anode). The dramatic performance loss was typical for the highly oxidizing condition, as carbon loss in the cathode reduces catalytic activity and as pore space collapses. EIS at low and high overpotentials confirmed that both kinetic and mass transport resistances increased.

Water profiles at a constant current density of 0.8 A/cm² (constant water generation rate) are shown in Figure 4b. The consistent trend was of decreased water retention as the cell was increasingly corroded. Given the lowering of cell potential at constant current due to increasing resistances, we attributed the decreased water content to increasing internal heat generation and increasing transport from the MEA to channels. Surprisingly, we saw no evidence of increasing water holdup in the cathode, despite the tendency of corroded carbon surfaces to become more water-wetting [7]. Increased mass transport resistance during the AST was therefore attributed to collapse of porous pathways, instead of increased blockage by liquid.

Conclusions

Catalyst and electrode durability remains a primary degradation mode; however the durability of the electrode is also dependent upon the structure of the electrode. The structure of the electrode is dependent on the solvent structure of the electrode, and the ionomer used. The durability of the electrode may be related to ionomer long-range order and the mechanical strength of the electrode. Post-characterization of the membrane shows changes in crystallinity which are dependent upon relative location to the electrodes. Carbon corrosion induces decreased performance and changes in water content.

Future Directions

Identify and Quantify Degradation Mechanisms

Vary MEA materials to better define degradation mechanisms:

- Expand mixed hydrocarbon and perfluorinated sulfonic acid materials for unambiguous chemical analysis.

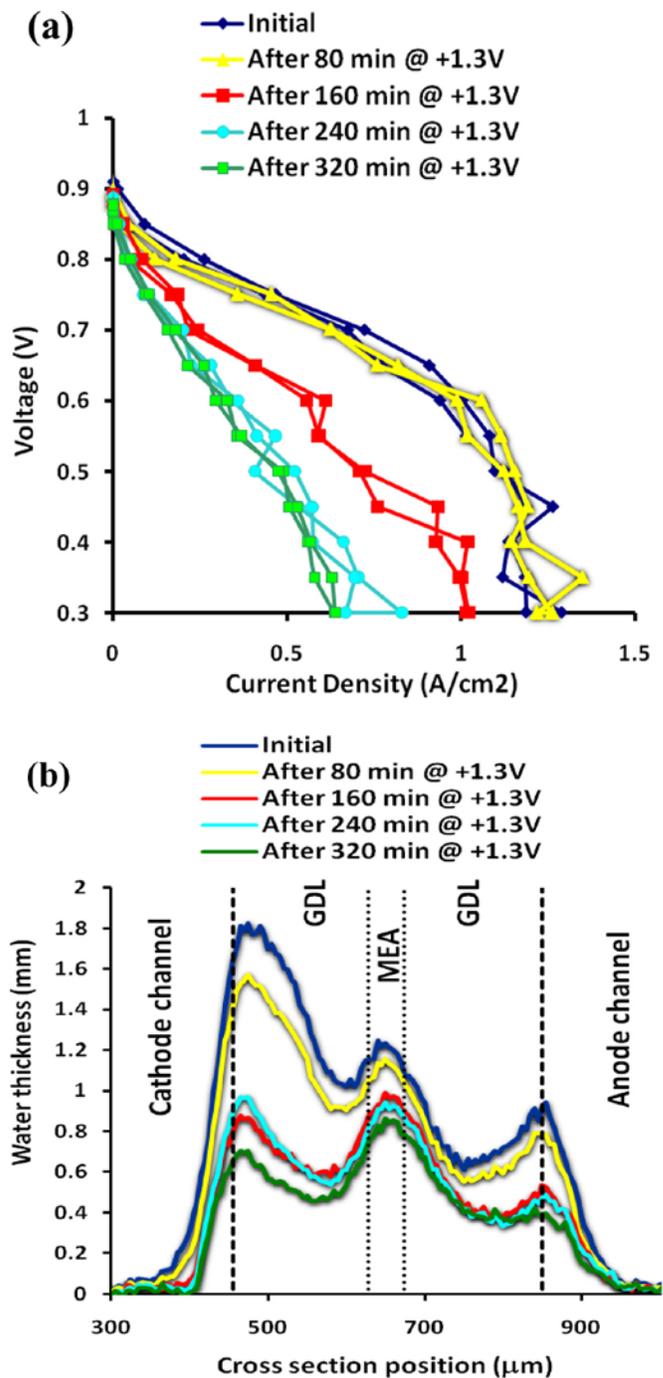

FIGURE 4. (a) Polarization curves for corrosion/imaging cell: 2.5 cm², Gore[®] 510 MEA, SGL[®] 24BC GDLs; H₂/Air, 80°C, 100% relative humidity (RH). (b) Through-plane water profiles for the above cell at a constant current density of 0.8 A/cm², 80°C, 100% RH. Profiles calculated from 20 min. neutron transmission images.

Evaluate degradation rates with MEA materials; guide integrated model development:

- Material variants include: ionomer, membrane, catalyst, support, electrodes.

- >30 MEA variants, >6 AST tests, >3 fuel cell durability tests.
- Incorporate DOE Durability Working Group protocols into testing shutdown/startup.
- Differential scanning calorimetry (DSC) of ionomer identifying changes in water bonding with age.

Electrode Structure

Identify causes behind ionomer and solvent impact on MEA durability:

- Combine microscopic, porosimetry, helox, O₂, and alternating current impedance information.
- Develop model for the SANS data already obtained from electrodes.

Establish correlation of electrode structure durability to mechanical strength:

- Assess mechanical properties and interface strength of electrode measurements.
- Correlate voltage-current-resistance durability by scratch testing of electrodes by nanoindentation.
- Develop test to be used to screen quality of dispersions intended for electrodes.

Assess short-side-chained ionomers using dispersion approach for potential cycling/OCV durability:

- Expand electrode structure durability testing to include fuel cell life testing.
- Extend study of electrode durability by characterization at various MEA life points.

Component Interactions

Five-cell short stack of ~2,000 hours with previously untested seal materials:

- Analyze product water for contamination over the test time.
- Link contaminant type from stack operation to that determined by leach investigation.
- DSC of aged material samples to see if their respective time to oxidation changes.

Metal bipolar plate evaluation and evaluation of interactions with MEA/GDL composite (graphite) bipolar plate evaluation:

- Surface evaluation improving data consistency to evaluate surface properties.

Correlate GDL properties and cell water profile measurements to surface property changes.

Modeling

Water profile modeling during carbon corrosion comparing overpotential and hydrophobicity changes to water transport. Correlate experimental data with detailed membrane modeling to allow prediction of synergistic effects on membrane degradation. Completion of Pt Dissolution Model and Pt Transport Model:

- Addition of impurity degradation.
- Inclusion of other component durability models into integrated model.

Contract Number: DE-EE0003772

Subcontractors:

- Nissan Technical Center North America, Farmington Hills, MI
- Illinois Institute of Technology, Chicago, Illinois
- 3M, St. Paul, MN

Project Start Date: September 1, 2010
Project End Date: August 31, 2013

Objectives

- Develop and/or confirm accelerated tests designed to separate individual degradation mechanisms. The final tests must ensure that degradation mechanisms seen in membrane electrode assemblies (MEAs) tested in the project match experience from Nissan's previous stack tests.
- Develop an overall degradation model that correlates the stack operating conditions to degradation of the MEA. Data generated using the accelerated tests defined above will be used in the model.
- Develop MEAs with a design lifetime target of 5,000 hours with <7% degradation and that show a clear path towards meeting the DOE 2015 technical targets.

Technical Barriers

This project addresses technical barriers from Section 3.4 – Fuel Cells, of the Fuel Cell Technologies Program Multi-Year Research, Development and Demonstration Plan. The primary technical barrier addressed is:

(A) Durability

There are also some basic requirements in

(C) Performance

but this is a secondary concern, aimed primarily at having performance acceptable to Nissan in order to run the stack test, and to ensure that the durability model is relevant to current materials.

Technical Targets

In order to meet the objectives, a series of milestones were developed that act as technical targets. The last two milestones have Go/No-Go criteria to be met before they are completed. None of the milestones have yet been completed.

- Decide which accelerated tests will be used in addition to DOE specified tests. Tests will be selected based on results of post-mortem analysis. Target date: 5/31/2011.
- Select specific low-equivalent weight membrane for use in stack test. The membrane design must meet accelerated durability targets with results verified in repeated lab testing. Target date: 10/31/2011.
- Define MEA design for stack test. The MEA will be based on durable materials as determined in the lab testing, and must meet minimum performance and durability goals. Target date: 3/31/2012.
- If data generated from the accelerated tests can be shown to discriminate among the various cell components, complete development of durability model. Target date: 8/31/2013.
- If MEA design meets targets, begin stack test to verify lab performance and durability model. Target completion date: 4/20/2013.

Fiscal Year (FY) 2011 Accomplishments

The project was divided into five tasks plus project management, which are more parallel than sequential. The accomplishments are organized by task. Only Task 1 and 2 have been worked on to date. Tasks 3 through 5 are listed for completeness, but no work has begun on these tasks

Task 1.0 Materials Synthesis

- Synthesize short-side chain polymer with desired properties for standard testing.
- Fabricate two standard membrane configurations using semi-commercial equipment.
- Apply semi-commercial coating of anode and cathode decals at desired platinum loading.

- Fabricate catalyst-coated membranes (CCMs) for initial durability tests at DuPont and Nissan.

Task 2.0 Accelerated Aging Tests

- Upgraded test equipment to handle specified DOE tests.
- Began initial accelerated tests at DuPont and Nissan.
- Testing currently in progress includes DOE, Nissan and US Fuel Cell Council accelerated tests.

Task 3.0 Analysis and Modeling

Task 4.0 Stack Testing

Task 5.0 Materials Characterization and Analysis

Introduction

This project deals with the study of the stresses and forces expected in an automotive fuel cell stack operating under real-world driving conditions. For the fuel cell stack, these driving conditions include a wide variety of conditions that stress various components that make up the fuel cell stack. For instance, at high temperature ($>80^{\circ}\text{C}$) and low relative humidity (RH) conditions, the conductivity of many membranes becomes low, resulting in the failure of fuel cell operation [1]. Moreover, membrane mechanical properties also deteriorate under prolonged humidity cycling, leading to membrane failure [2]. The DOE considers the durability of fuel cell components to be among the major technical barriers for successful implementation of fuel cell systems. The minimum required life expectancy for automotive fuel cell stacks is 5,000 hours.

Incremental improvements will not suffice to bridge the gap between today's technology and the market requirement. This project is focused on both improving the understanding of the mechanisms of component failure, and rapidly incorporating this understanding into component design and thus accelerate the delivery of proton exchange membrane fuel cells (PEMFCs) into the marketplace.

Approach

Degradation mechanisms for all stack components are being studied at varying levels of detail. At a high level, the determination of degradation mechanisms consists of the following tasks:

- Chemical degradation studies of the ionomers, not only in the membrane but also in the catalyst layer.
- Analysis of how chemical degradation impacts water management in the membrane and electrode layers.

- Understanding of the effect of realistic automotive cycling operation on the degradation of MEA components.
- Definition of the mechanisms and conditions that promote MEA degradation not only at a single cell level, but in the environment of an automotive fuel cell stack.
- Fabrication and delivery of an MEA that has improved resistance to degradation for evaluation in a full-scale short stack.

These studies on materials both before and after running the accelerated tests will be used first to compare with Nissan stack results and define the best set of accelerated tests to use in this project. The testing and analyses will then be extended to a range of components, so that a quantitative model of stack degradation can be developed.

Next, the results of degradation mechanism work will be used to develop methods to mitigate some of these mechanisms in order to increase the durability of the membrane electrode assemblies. The improved MEAs will be used in a stack test at Nissan to verify both the model and the improvements in durability.

Results

The start of the testing program has been delayed while confidentiality agreements and subcontracts were being worked out among the parties. The confidential disclosure agreements were signed in June 2011, and materials were then shared so testing could begin. The completion of these agreements also allows the legal work on the actual contracts to begin.

While the agreements were being negotiated, the work focused on defining, fabricating and purchasing the base materials. Because the project is defined for a certain class of short side-chain polymers, the first task in the project involved preparation of materials to be used in the evaluation of the accelerated tests. A short side-chain polymer with the desired range of properties was synthesized in semiworks-scale equipment. Some of this material was converted to dispersion, and several small lots of reinforced membranes were produced on semi-works scale equipment. The team agreed on the importance of testing repeatable materials from processes that could produce semi-commercial quantities of material and be scaled up easily. These membranes use an expanded polytetrafluoroethylene reinforcement, and DuPont's proprietary advanced stabilization system, and were made in nominal thicknesses of 16 and 27 microns. All membranes for the initial phase of the project use the same polymer composition.

The team agreed on using a specific commercially available cathode catalyst. The catalyst consists of 50% Pt on an acetylene carbon black support. A supply of cathode decals based on this ink formulation was produced on the semi-commercial coating line. Both 0.15 and 0.35 mg Pt/cm² loadings were produced. This decal supply will be used for the remainder of the accelerated test evaluation work. It is not optimized for either performance or durability, but is

in the right performance and property range for evaluation of testing methods.

The semi-commercial decals were then transferred to N211 and tested under our standard conditioning test to ensure the material quality. These results were compared to CCMs using previous generation materials. These results led us to the conclusion that the electrodes are suitable for the next phase of the work. Once the suitability of the materials was confirmed CCMs were prepared for initial durability tests at DuPont and Nissan.

Test equipment at DuPont was upgraded to handle specified DOE tests, which differed considerably from DuPont's internal testing. Both Nissan and DuPont have begun the accelerated tests of the base materials, but significant test results are not yet available.

Conclusions and Future Directions

Short-Term

- Complete contractual arrangements for all subcontractors and participants.
- Complete automation of DOE Durability Test Protocols.
- Complete analysis of baseline materials.
- Complete first set of accelerated tests and begin post-mortem analyses.

- Make decision on acceleration tests to use in the model development. We anticipate a overall delay of six months due to the timing of the confidentiality agreement and formal contracts.

2011-2012

- Fabricate alternative membranes and CCMs and complete designed experiment to better define effects of material properties on degradation.
- Fabricate durable materials for stack test.

- Los Alamos National Laboratory, Los Alamos, NM (R. Borup)
- Michigan Technological University, Houghton, MI (J. Allen)
- Queen's University, Kingston, Ontario (K. Karan, J. Pharoah)
- University of New Mexico, Albuquerque, NM (P. Atanassov)

Project Start Date: January 1, 2010

Project End Date: March 31, 2013

Fiscal Year (FY) 2011 Objectives

- Identify/verify catalyst degradation mechanisms, i.e. Pt dissolution and transport/ plating), carbon-support oxidation/corrosion, ionomeric thinning/conductivity loss, and mechanism coupling/feedback/acceleration.
- Correlate catalyst performance/catalyst structural change as a function of unit cell operational conditions, catalyst layer morphology/composition, and gas diffusion layer (GDL) properties.
- Develop kinetic and material models for catalyst layer aging, i.e. macro-level unit cell model, micro-scale catalyst layer model, and molecular dynamics model of the platinum/carbon/ionomer interface.
- Develop mitigation strategies for catalyst degradation through modification of: operational conditions and component structural morphologies/compositions.

Technical Barriers

This project addresses the following technical barriers of the DOE Fuel Cell Technology Program Multi-year Research, Development, and Demonstration Plan. This plan can be accessed at <http://www.eere.energy.gov/hydrogenandfuelcells/mypp/>.

(A) Durability

Pt catalyst and Pt catalyst layers degradation:

- Effect of cathode structure and composition
- Effect of operational conditions

(B) Performance

- Effect of cathode catalyst structure and composition

(C) Cost

Technical Targets

This project conducts fundamental studies of Pt/carbon catalyst degradation mechanisms and degradation rates which are correlated with unit cell operational conditions and catalyst layer structure and composition. Furthermore, forward predictive micro and macro models for cathode performance and degradation are being developed. Design curves will be generated, both through model simulations and experimental work, enabling membrane electrode assembly (MEA) designers to optimize performance, durability, and cost towards the 2015 stack targets for fuel cell commercialization [1]:

- Durability: 5,000/40,000 hrs (2015 transportation/2011 stationary application target)
 - Electrocatalyst Support Loss: <30 mV after 100 hrs @ 1.2V
 - Electrochemical Surface Area (ECSA) Loss <40%
- Cost: \$15/kW_e
 - Precious Group Metal (PGM) total loading: 0.2 mg

FY 2011 Accomplishments

- Validated the one-dimensional (1D), 2-phase MEA model with statistical inputs for material, design, and operational deviations within the 95% variability of the experimental data (baseline MEA).
- Developed a molecular-dynamics-based description of the Pt/C/ionomer system.
- Expanded the micro-structural and 1D-MEA Model for 2-phase flow.
- Quantified Pt/C cathode catalyst layer degradation (performance loss and structural changes) as a function

of carbon catalyst support type, ionomer loading, upper potential voltage cycling in the accelerated stress test (AST), and number of AST cycles.

Introduction

Catalyst/catalyst layer degradation has been identified as a substantial contributor to fuel cell performance degradation and this contribution will most likely increase as MEAs are driven to lower Pt loadings in order to meet the cost targets for full-scale commercialization. Over the past few years significant progress has been made in identifying catalyst degradation mechanisms [2,3] and several key parameters that greatly influence the degradation rates, including electrode potentials, potential cycling, temperature, humidity, and reactant gas composition [2,4-6]. Despite these advancements, many gaps with respect to catalyst layer degradation and an understanding of its driving mechanisms still exist. In particular, acceleration of the mechanisms under different fuel cell conditions, due to different structural compositions, and as a function of the drive to lower Pt loadings remains an area not well understood. In order to close these gaps an understanding of the effect of operating conditions and the layer structure and composition on catalyst layer degradation mechanisms and degradation rates is needed.

The project focus is to develop forward predictive models and to conduct systematic cell degradation studies that enable the quantification of the cathode catalyst layer degradation mechanisms and rates, as well as the coupling between mechanisms for key operational and structural stressors.

Approach

Models will be developed at the molecular, micro-structural, and macro-homogeneous scales that include degradation effects related to platinum dissolution, transport and plating, carbon surface oxidation and corrosion, and ionomer thinning/conductivity loss. The models will provide the ability to study the effects of composition, the morphological design, and the operational window on catalyst degradation via simulated ASTs. The design curves generated in each scale of the modeling work will enable the development of mitigation strategies through trade-off analysis.

Accelerated stress testing coupled with ‘state-of-the-art’ in situ/ex situ characterization techniques will be used to correlate MEA performance loss with structural changes measured within the Pt cathode, as well as to develop key operational and catalyst/catalyst layer structural degradation design curves. The experimental results will also serve to provide model validation.

Results

Under the modeling tasks, molecular modeling was used to determine the cohesive energy for the Pt clusters and its interaction with H₂O and O₂, carbon and the ionomer. The Microstructural Catalyst Model has been extended to include 2-phase flow in order to simulate the capillary transport inside the catalyst structure. Furthermore, the model has been used to extract effective properties for the low surface area catalysts used in the project, with the results currently implemented in the Macro MEA model. The Macro MEA model was re-scripted in a manner that separated relevant sections of model functionality into self-contained modules enabling the use of statistical inputs based on component to component and operational variability. Shown in Figure 1(a), the model was validated using experimental data generated with different MEAs and test-stands. The model validates within the 95% variability of the experimental data for current densities up to ~1,000 mA/cm². Beyond this point the experimental and model data diverge, the discrepancy is believed to be due to the formation of liquid water and its interaction statistically with the MEA structure. To improve the validation, a 2-phase flow module was implemented and a repeat of the validation shows the improved mass transport predictions over the entire polarization range, Figure 1(b), such that the model is fully validated within the 95% variability of the experimental data.

The key operational and structural stressors affecting catalyst layer durability were identified and prioritized based on literature and Ballard data. With a focus on the catalyst layer structure and composition, the impact of catalyst carbon support type, catalyst layer ionomer content, and cathode catalyst layer degradation was investigated using ASTs. In addition, selected designs were also investigated for performance degradation and catalyst layer structural changes as a function of AST upper potential and as a function of AST cycle number. The MEAs were in-house catalyst-coated Nafion® membranes with a anode and cathode loading of 0.1/0.4 mg/cm², respectively, and Ballard Material Products’ GDLs. The AST standard conditions are: 80°C, 100% relative humidity (RH), air/H₂, square wave cycle from 0.6 V (30 s) to 1.2 V (60 s) for 4,700 cycles. Comprehensive cell diagnostics and characterization were conducted after 50, 700, 1,400, 2,100, and 4,700 cycles and failure analysis was performed at the end of the stress test (4,700 cycles).

The effect of ionomer loading on Pt dissolution/corrosion was investigated for a range of 12 to 50 wt% Nafion® content using a Pt catalyst supported on a low surface area carbon (LSAC). The MEAs were subjected to AST testing (1.2 V upper potential limit, 4,700 cycles). The key findings were:

- ~30% ionomer loading yields optimal beginning of test (BOT) performance in agreement with literature results [7] and internal model predictions.

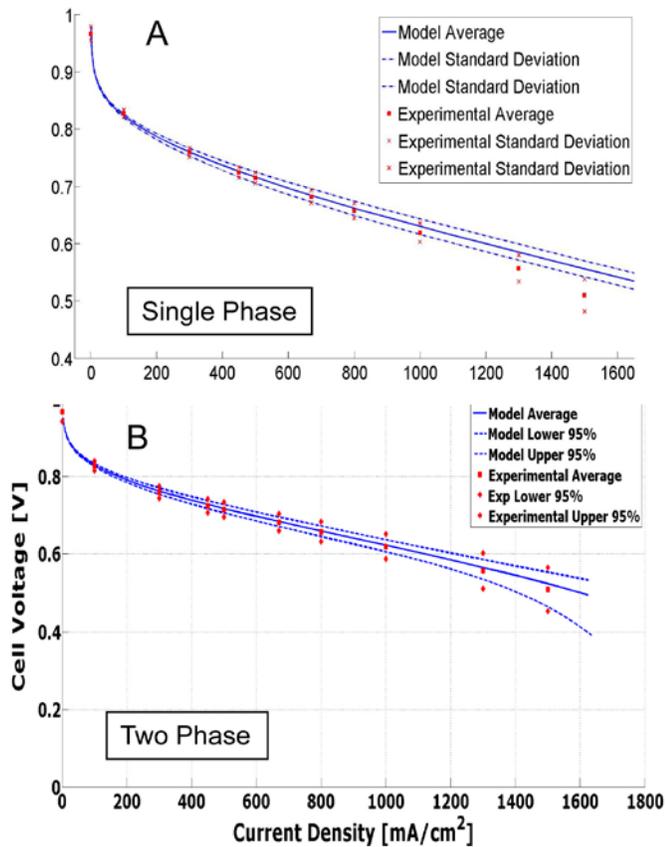

FIGURE 1. 1D MEA Model: Comparison of statistical model predictions with experimental data (a) single phase flow using input parameter uncertainty of 1 standard deviation, (b) 2-phase flow using input parameters confidence level of 95%.

- The ionomer content impacts the BOT catalyst structure: catalyst layer porosity decreases with increasing ionomer loading, Figure 2(a).
- After 4,700 AST cycles end of test (EOT) the highest ECSA loss occurs at an ionomer content of ~30 to 40%, Figure 2(b). The voltage loss is dominated by cathode catalyst layer ionic loss.

The effect of catalyst carbon support type on catalyst performance and degradation was studied using a variety of Pt catalysts supported on different carbons (surface area from $<200 \text{ m}^2/\text{g}$ to $800 \text{ m}^2/\text{g}$) at an upper AST potential of 1.0 and 1.2 V. The catalyst powders and carbon support materials were analyzed for surface species, morphology, and particle distribution.

Transmission electron microscope micrographs revealed a carbon aggregate structure with graphitic walls and amorphous center for the LSAC; the mid-range carbon support (MSAC) and Vulcan (V) also exhibit some graphitic walls that are in general less uniform. One of the high surface area carbons (HSAC1) showed some graphitic centers throughout the aggregates; while a second one

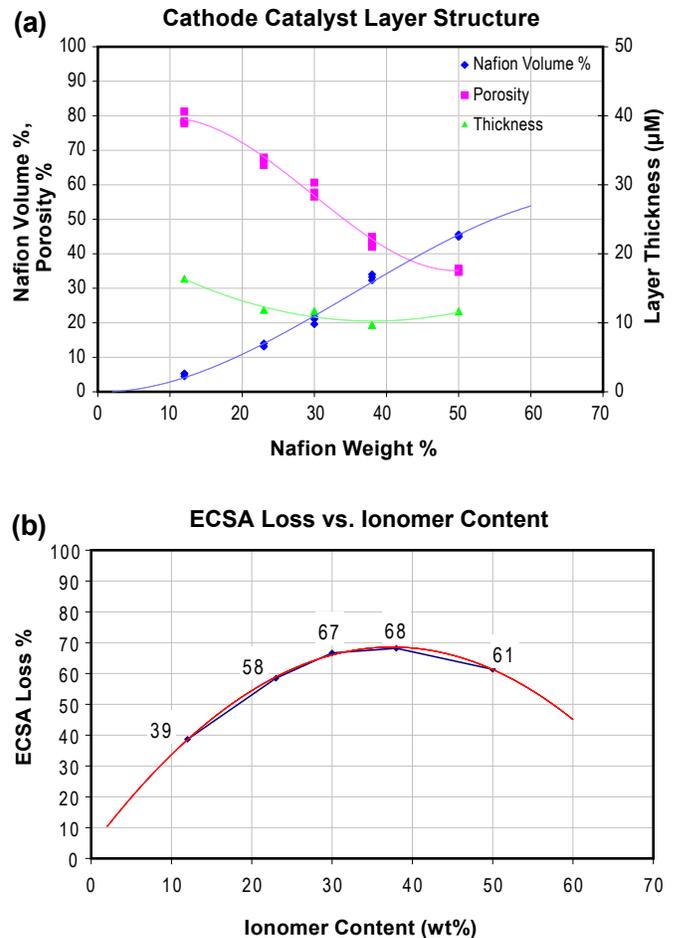

FIGURE 2. Effect of ionomer content in the cathode on (a) catalyst layer structure and (b) cathode ECSA loss after 4,700 AST cycles.

(HSAC2) showed a highly amorphous structure. It was also noticeable that the Pt distribution on the different supports becomes more dispersed with increasing surface area.

In general, Pt catalysts supported on high surface area carbon exhibited higher BOT performance due to higher ECSA; however, the carbon surface structure and surface functionality were found to also have a significant impact on the catalyst layer structure and its resistance to corrosion. The key findings were:

- The BOT performance did not show a clear trend with the carbon support surface area.
- Cycling at 1.0 V upper potential limit (UPL) exhibited similar Pt dissolution and minimal carbon oxidation for all investigated carbons.
- Cycling at 1.2 V UPL showed increased Pt dissolution, Pt agglomeration and Pt in the membrane with increasing carbon surface area due to greater catalyst ECA and Pt dispersion. As expected, greater Pt surface area and distribution enhanced the Pt catalysis of the

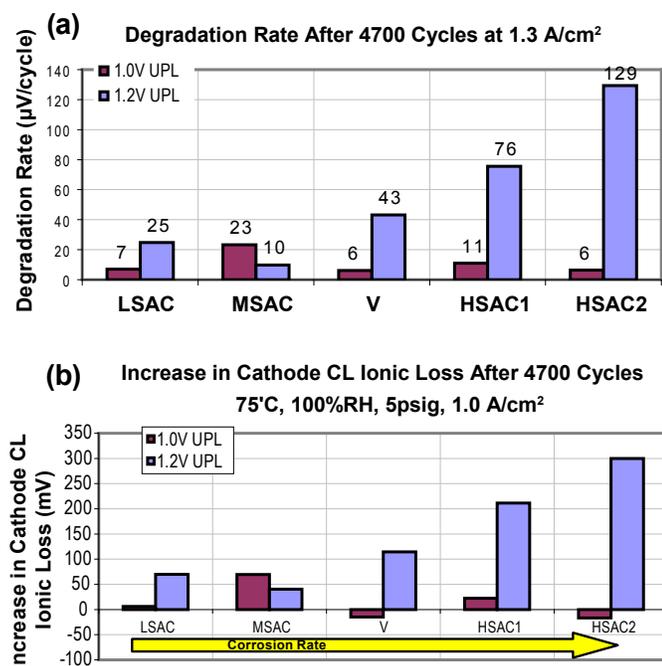

FIGURE 3. (a) Voltage degradation rate and (b) cathode catalyst layer ionic resistance loss after 4,700 AST cycles at an upper potential of 1.0 and 1.2 V for a variety of carbon supports (LSAC - Low, MSAC - Medium, HSAC - High Surface Area Carbon support, V - Vulcan).

carbon support, thus catalyst layer thinning increased with increasing carbon surface area.

- The cathode catalyst layer performance and specifically the ionic resistance were impacted significantly by corrosion, most severely for high surface area carbon supports (Figure 3). The MSAC catalyst was found to be an exception to the trend, likely due to enhanced carbon surface oxidation causing increased cathode catalyst ionic conductivity and consequently higher performance.
- The carbon structure and morphology impacts catalyst layer durability. Pt dissolution (ECSA/kinetic loss) and corrosion (cathode layer ionic/thickness loss) decreased linearly with increasing graphitic content of the carbon support surface.

The effect of upper potential on catalyst layer degradation was studied by subjecting Pt catalysts on MSAC and LSAC supports to AST cycling at upper potentials from 1.0 to 1.4V. The two catalysts exhibit similar platinum dissolution and support corrosion trends with some subtle differences in degradation rates. The LSAC catalyst was found to be slightly more stable at an UPL ≤ 1.3 V; however, it was notably less stable than the MSAC catalyst at a UPL ≥ 1.3 V which may be associated with the collapse of the LSAC aggregates due to severe corrosion of the amorphous centers.

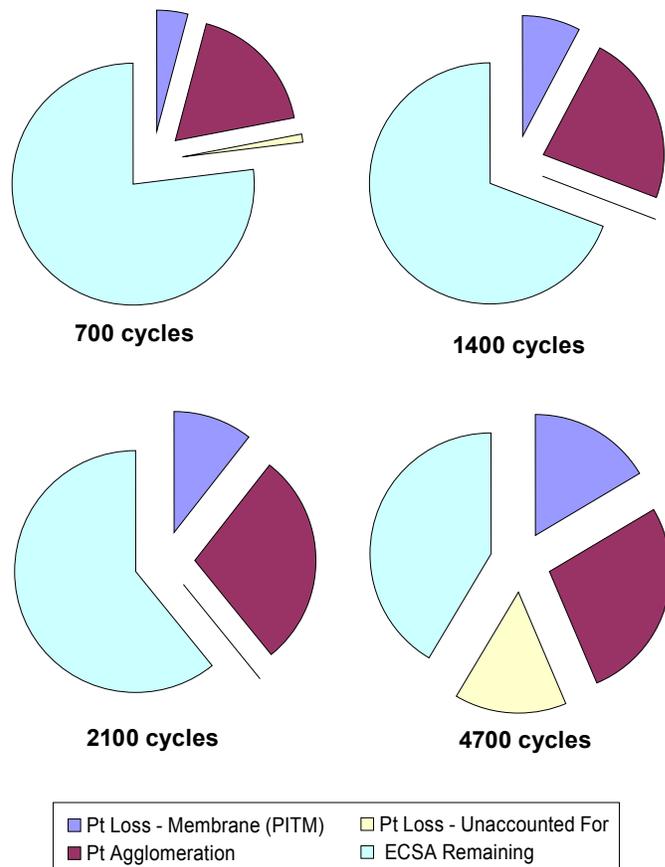

FIGURE 4. Pt loss break-down (Pt agglomeration, Pt in the membrane, and “unaccounted for Pt” at 50, 700, 1,400, 2,100, and 4,700 AST cycles with 1.2 V upper potential.

The impact of AST cycle number on catalyst layer degradation was investigated to quantify changes in degradation mechanisms for the LSAC catalyst with progressive AST cycling. MEAs using the LSAC catalyst were cycled at 1.2 V UPL to different EOT cycle numbers (50, 700, 1,400, 2,100, 4,700 cycles). A significant ECSA loss was observed after only 50 cycles; for $< 2,100$ cycles the kinetic losses were found to dominate (Pt dissolution, agglomeration, Pt in the membrane); while at cycles $\geq 2,100$ the catalyst layer ionic losses became dominant due to the onset of carbon corrosion (catalyst layer thinning). The Pt loss with cycle number with respect to the total initial Pt in the catalyst layer, measured as ECSA, is depicted in the pie chart in Figure 4 as follows: 1) the fraction labeled “ECSA remaining” is still active; 2) the fraction labeled “Pt agglomeration” is ECSA lost due to Pt agglomeration; 3) the fraction labeled “Pt Loss - Membrane (PITM)” is Pt ECSA lost due to dissolved Pt depositing in the membrane; 4) the fraction of initial ECSA lost that can’t be accounted for by Pt agglomeration or the Pt found in the membrane is labeled “Pt loss - Unaccounted For” and is presumed to be due to support corrosion and Pt particle detachment from the support.

Conclusions

The interim conclusions are:

- The 1D MEA Model, with 2-phase flow, has been validated within the 95% variability of the experimental data for the entire current density range (up to 1.5 A/cm²). Additionally, the model has been validated across a range of catalyst compositions and operational conditions.
- The catalyst layer ionomer content affects the catalyst layer structure (porosity). Optimal performance and lowest degradation rate were observed for 30% ionomer content (LSAC catalyst).
- The Pt catalyst carbon support surface area is not the only measure of susceptibility to catalyst support corrosion; the catalyst layer structure and carbon functionality play an important role. The graphitic content of the carbon surface correlates linearly with degradation.
- BOT performance does not show a clear trend with carbon support surface area except for kinetic losses which decrease with increasing surface area. However, catalyst degradation increases with increasing carbon surface area, i.e. higher Pt dissolution (ECSA loss, Pt agglomeration, and Pt in the membrane) and higher corrosion (ionic resistance loss, catalyst layer thickness loss).

Future Directions

- Investigate catalyst degradation rates (Pt dissolution and carbon corrosion) as a function of the Pt/carbon ratio, cathode catalyst loading, and ionomer equivalent weight.
- Correlate degradation with catalyst material properties.
- Model Pt dissolution on the molecular scale.
- Refine two-phase flow implementation and validation for both the micro-structural catalyst and 1D-MEA model (linkage of the two scales).
- Expand the micro catalyst layer and 1D MEA models to transient operation and develop/include degradation mechanisms.
- Integrate electrical contact resistance model with the 1D MEA model.

Contract Number: DE-EE0000469

Subcontractors:

- Los Alamos National Laboratory, Los Alamos, NM
- Argonne National Laboratory, Argonne, IL

Project Start Date: September 1, 2009

Project End Date: August 31, 2013

Fiscal Year (FY) 2011 Objectives

- The objective of this project is to study and identify strategies to assure durability of fuel cells designed to meet DOE 2015 cost targets.
- Develop a practical understanding of the degradation mechanisms impacting durability of fuel cells with low platinum loading (≤ 0.2 mg/cm²) operating at high power density (≥ 1.0 W/cm²).
- Develop approaches for improving the durability of low-loaded, high-power stack designs.

Technical Barriers

This project addresses the following technical barriers from the Fuel Cells section (3.4.4) of the Fuel Cell Technologies Program Multi-Year Research, Development and Demonstration Plan:

- (A) Durability
- (B) Cost

Technical Targets

TABLE 1. Progress towards Meeting Technical Targets for Transportation Fuel Cell Stacks Operating on Direct Hydrogen for the Transportation Applications

Characteristics	Units	2010/2015 Stack Targets	Nuvera 2010 Status
Cost	\$/kWe	25/15	~22 estimated ¹
Durability with Cycling	Hours	5,000	9,000 hrs ² 2,000 hrs in automotive cycle conditions ³
Performance at Rated Power	mW/cm ²	1,000	1,100 ⁴ and 1,200 ⁵

¹ Cost assessment of Nuvera's architecture by Directed Technologies Inc. based on their DOE-sponsored DFMA[®] (Design for Manufacturing and Assembly) model [1] and comparing the results to an updated "Industry" estimate. 0.55 V/cell @2.0 A/cm² was obtained at 0.2 mg/cm² platinum loading on Orion stack by Nuvera.

² Demonstrated under power profile specific-to-fork truck applications in material handling market at total platinum loading of 0.5 mg/cm².

³ Demonstrated in 360-cm² stack by Nuvera in simulated combined city and highway driving cycle at platinum loading of 0.50 mg/cm².

⁴ Demonstrated in 250-cm² Orion stack by Nuvera at platinum loading of 0.2 mg/cm².

⁵ Demonstrated in 50-cm² single cell with open flowfield (SCOF) by Nuvera at platinum loading of 0.2 mg/cm².

FY 2011 Accomplishments

- Two program milestones were completed on schedule. The first milestone comprised the development of the durability model framework by Argonne National Laboratory (ANL). The second milestone was achieved with Nuvera delivery of SCOF hardware to Los Alamos National Laboratory (LANL) for characterization and testing under accelerated stress test (AST) conditions and new stress testing representing combined power cycle (NST) protocols.
- The material sets selected for the project in standard 0.45 mg/cm² (A) and custom 0.2 mg/cm² (B) platinum loadings were delivered by W.L.Gore for various 50 cm² single cells including quad-serpentine, SCOF and General Motors/Rensselaer Institute of Technology architectures, as well as for 250- and 360-cm² cells for short stack testing. The material development scope of the project is completed.
- SCOF hardware was validated at the range of current densities up to 3 A/cm² and demonstrated ohmic, diffusion, and pressure drop benefits over the land-channel cells at Gore and LANL. Catalyst-coated membranes A and B were characterized at the beginning of life (BOL) in Nuvera 50-, 250- and 360-cm² cells and LANL 50-cm² hardware throughout the range of operating conditions.

- The AST campaign in LANL quad-serpentine cell was completed on all selected membrane electrode assemblies (MEAs) and test protocols. The data analysis concluded that the observed cell voltage decays resulted from the increased activation and mass transport overpotentials in the wide range of operating current densities.
- ANL evaluated platinum dissolution in aqueous media using polycrystalline and dispersed platinum on carbon electrodes, completing the ground work for further development of the platinum stability section of the durability model.
- Durability testing in short stacks continued at Nuvera under NST protocols.

Introduction

Understanding and improving the durability of cost-competitive fuel cell stacks is imperative to successful deployment of the technology. Stacks will need to operate well beyond today's state-of-the-art rated power density with very low platinum loading in order to achieve the cost targets set forth by DOE (\$15/kW) and ultimately be competitive with incumbent technologies. Little to no study of durability factors has been carried out in this area of design and operation. The industry today is focusing mostly on reduced platinum loading as it heads for the DOE target point of 0.2 mg/cm² platinum and 1.0 W/cm² power density. As demonstrated through DOE-sponsored cost modeling, this point falls short of the corresponding \$15/kW stack cost target for 2015.

Approach

Nuvera proposes an accelerated cost-reduction path focused on substantially increasing power density to address non-platinum group metals material costs as well as platinum. Understanding the largely unstudied factors affecting stack durability under these high power conditions is the focus of the present project. Of specific interest is the impact of combining low platinum loading with high power density operation, as this offers the best chance of achieving long-term cost targets. The team effort is divided into two activities: modeling and experimentation.

Results

During the past year, two project milestones were completed on schedule. Development of the durability model framework by ANL concluded the first milestone. A durability model is being developed specific to the platinum stability of the selected commercially available material set (cathode 580 and 15-micron membrane M815 by W.L. Gore), independent of the cell architecture. Our

modeling approach starts from platinum aqueous kinetics, defining rates for platinum dissolution and re-deposition as well as oxide coverage and continues at the electrode level for platinum ion transport. The model will utilize inputs from catalyst cycle ASTs, BOL properties of the studied material set, and prescribed use cycles to output cathode electrochemical surface area (ECSA), particle size distribution, overpotentials and cell voltage as a function of cycle time and the current density. The second milestone was achieved by delivery of SCOF hardware to LANL for characterization in ASTs and NSTs.

Development efforts were focused on further SCOF validation for performance at elevated current densities and for stability, comparing to the same diagnostics of full format area cells in Nuvera short stacks. Polarization curves of MEAs A and B in SCOF in Figure 1 showed repeatable results in multiple cell assemblies, proving control and uniformity of compression over the active area. Low resistivity and pressure drop of the open flow fields resulted into measurable performance benefits over the quad serpentine cell. High power densities above the DOE target of 1 W/cm² were demonstrated in both SCOF and open flowfield short stack tests at 2 A/cm², proving the diffusion benefits of open flowfield over the land-channel architecture, tested at Gore and LANL. While the performance of MEA B in land-channel cell was limited below 2 A/cm² at low pressure conditions, 1.2 W/cm² power density was achieved on the same MEA at 2 A/cm² in SCOF.

Over the past year the AST campaign in the quad serpentine cell was completed and currently moved to SCOF. ASTs focused on the electrocatalyst stability under the B1 potential cycle protocol and membrane mechanical stability under the B4 humidity cycle protocol defined by the DOE. In addition, the low platinum cell was subjected to the modified potential cycle test with the lower potential

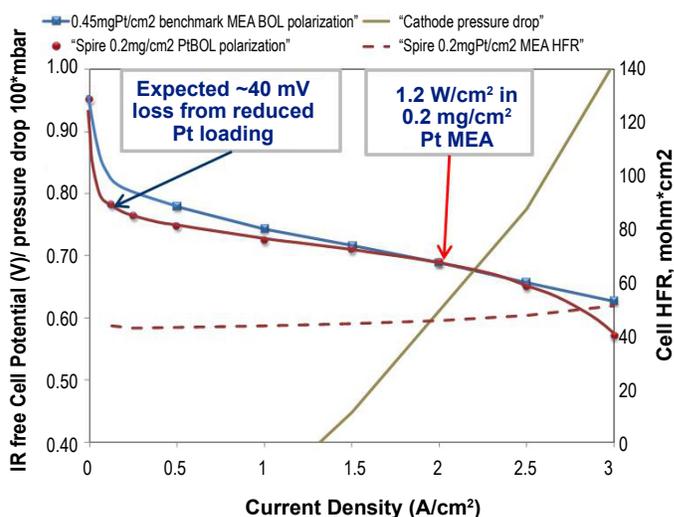

FIGURE 1. Ohmic Resistance-Free Polarization of MEAs A and B in SCOF (Dry cathode, 1.8 bara inlet pressure)

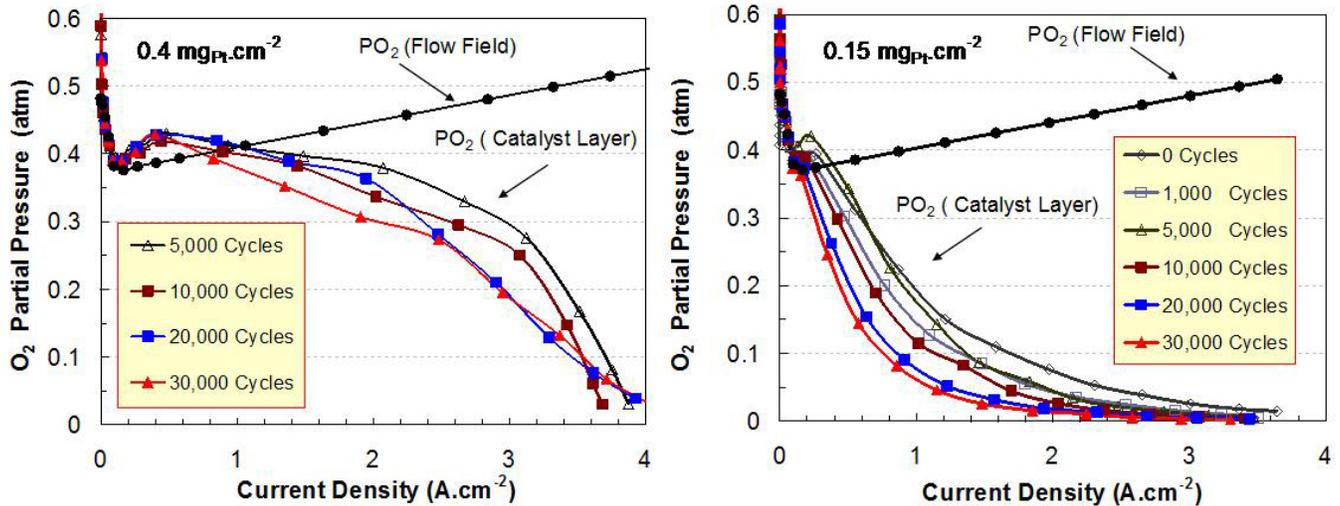

FIGURE 2. Effect of Ageing in B1 AST on the Cathode Oxygen Partial Pressure in MEAs with different Platinum Loading

range of the cycle than in the B1 test. The potentials in the modified cycle protocol correlate with cell voltages achieved in Nuvera large-area cells at 2 A/cm², resulting in significant improvement in cathode ECSA stability and less platinum dissolution into the membrane, confirmed by the post-mortem scanning electron microscopy and energy disperse spectroscopy analyses.

AST data, including polarization, ECSA, and impedance diagnostics from all potential cycles obtained in both normal and low-platinum cell tests were analyzed at low and high pressure conditions to determine the effect of ageing on the kinetics of the oxygen reduction reaction (ORR) and on oxygen mass transport. The model based on the electrochemical impedance spectroscopy data at different current densities was set up to distinguish oxygen mass transport coefficients between the cathode catalyst and gas diffusion layers. Observed cell voltage decays were attributed to the increase of activation and mass transport overpotentials in the ASTs and the respective decay of oxygen partial pressure in cathodes in Figure 2.

Durability testing in short stacks continued under the NST3A-2 protocol, representing a combined city and highway driving cycle designed at 2 A/cm² rated current density and average cell voltage response shown in Figure 3. In this NST the cathode pressure and flow conditions vary with the current density, following the operating map of the air compressor in the automotive system. Data obtained during 1,000-1,600-hour testing of three stacks were processed using ohmic resistance-corrected, polarization data at low current densities to determine the Tafel slope for the ORR kinetics. Our analysis of ECSA loss from voltage-current (V-I) curves showed consistency with direct measurements by cyclic voltammetry and correlated to the increase of average platinum particle diameter by X-ray diffraction analysis as shown in Figure 4. V-I analysis allowed calculating oxygen partial pressures in the cathodes

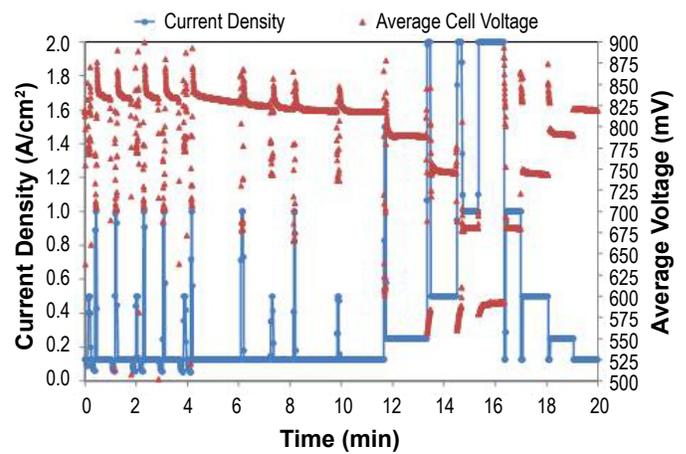

FIGURE 3. Performance of Nuvera Short Stack with MEA A under Simulated Combined City and Highway Drive Load Cycle

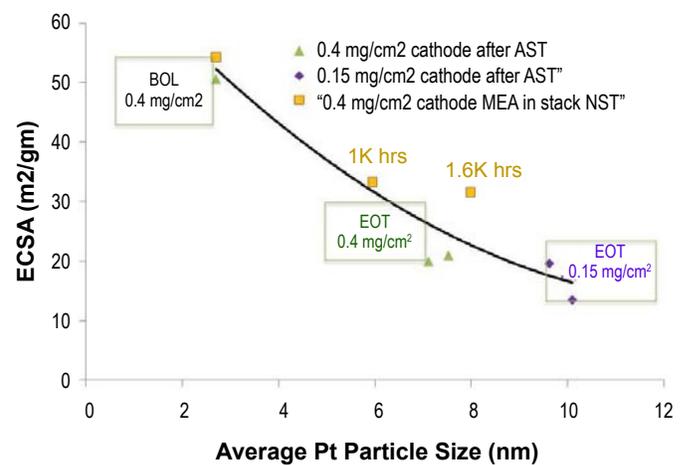

FIGURE 4. Correlation of Cathode ECSA to Average Size of Platinum Particles in ASTs and Stack NSTs

with different loadings at all operating current densities and showed decreasing values from BOL to the end of test.

Conclusions and Future Directions

- Operation at high power densities enabled by the open flowfield architecture and proven at the low platinum loading provided the ground work for accelerated cost-reduction path to the cost targets set by the DOE.
- Two milestones concluded in the reported year served as the basis for experimental and modeling activity started and to be continued in the next year.
- The AST campaign will be moved from serpentine cell to SCOF towards achieving the third project milestone.
- Durability modeling will continue, focused on the platinum stability, and will be synchronized with other durability projects covering different ageing mechanisms with the same partners, extending the current project duration by one year at no cost to the DOE.
- The NST campaign in the large-format cells in short stacks and benchmarking the results between SCOF and large area cells will continue, targeting the Go/No-Go decision.

- Correlation of platinum decay in real-world operation and lab AST complete.
- Lab ASTs for platinum degradation complete.
- Lab ASTs for carbon support corrosion complete.
- Lab ASTs for membrane mechanical degradation complete.
- Lab ASTs for membrane chemical degradation complete.
- Accelerated life test (ALT) complete.

Approach

UTC will lead a top-tier team of industry and national laboratory participants to update and improve DOE's ASTs for hydrogen fuel cells. This in-depth investigation will focus on critical fuel cell components (e.g. membrane electrode assemblies [MEAs]) whose durability represents barriers for widespread commercialization of hydrogen fuel cell technology. UTC has access to MEA materials that have accrued significant load time under real-world conditions in PureMotion® 120 power plants used in transit buses. These materials are referred to as end-of-life (EOL) components in the rest of this document. Advanced characterization techniques are used to evaluate degradation mode progress using these critical cell components extracted from both bus power plants and corresponding materials tested using the DOE ASTs. These techniques will also be applied to samples at beginning of life (BOL) to serve as a baseline. These comparisons will advise the progress of the various failure modes that these critical components are subjected to, such as membrane degradation, catalyst support corrosion, platinum group metal dissolution, and others. Gaps in the existing ASTs to predict the degradation observed in the field in terms of these modes will be outlined. Using these gaps, new ASTs will be recommended and tested to better reflect the degradation modes seen in field operation. Also, BOL components will be degraded in a test vehicle at UTC designed to accelerate the bus field operation.

Results

Task 1 - Fleet Data Analysis

Fleet data analysis has been completed and has been reported previously.

Task 2 - Lab-World Degradation

UTC has facilitated the development of a test vehicle for accelerated evaluation of stack components under

Fiscal Year (FY) 2011 Objectives

- Correlate real-world operating conditions to cell degradation.
- Correlate existing DOE accelerated stress tests (ASTs) to degradation.
- Assess degradation modes between real-world operating conditions and existing DOE ASTs.
- Recommend modified ASTs that more accurately gauge in situ component behavior.
- Identify life-limiting mechanisms not addressed by current DOE ASTs and recommend new ASTs.

Technical Barriers

- > 5,000 hours stack durability (including cycling and all materials, e.g. membrane, seals).
- < 10% overall performance decay (including start/stop and transient operation).
- Current DOE ASTs not calibrated with real-world degradation.

FY 2011 Accomplishments

- Fleet performance and operating cycle analyses complete.

this project. The main motivation for this exercise results from the relatively slow rate of load-hour accrual for buses in the field. Because UTC Power is currently targeting >18,000 hours stack durability for bus fleet applications, a more rapid test vehicle is necessary to increase product maturity on new stack configurations. The test vehicle for accelerated stack component evaluation is termed the ALT. This small power plant has the identical piping and instrumentation configuration as the bus power plant, but operates on a 5-kW short stack. The key operating modes of the bus that have been linked to stack component degradation have been reflected in the protocol. The implementation of the ALT vehicle has been complete. Testing of the unit has been completed. The results are described in the following paragraphs.

Figure 1 shows the UTC bus fleet durability data. The 2006 fleet leader failed after 1,000 hours due to carbon corrosion of the cathode gas diffusion layer (GDL). A carbon corrosion AST was developed to evaluate resistance of cathode GDLs to oxidizing conditions. The protocol for this AST is summarized in Table 1. The acceleration factor

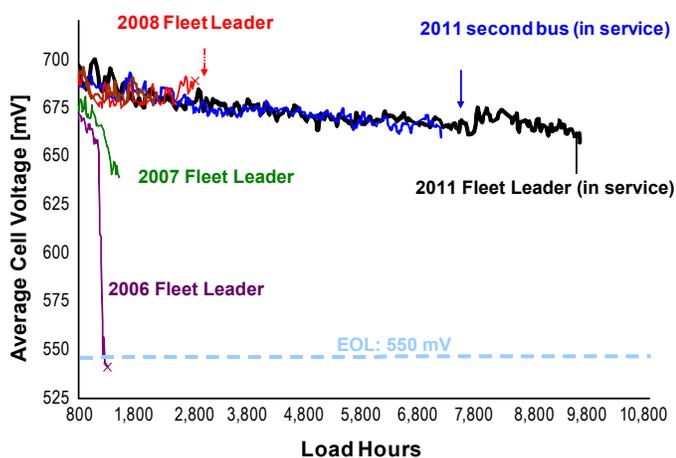

FIGURE 1. UTC Fleet Durability Data

TABLE 1. AST Protocol for Air-Air Cycling Test

Coolant inlet temperature (°C)	65°C		
Percent Relative Humidity	100		
Cell Current	0 Amps		
Reactant flow cycle	Time	Anode Reactant	Cathode Reactant
	5 minutes	H ₂	H ₂
	5 minutes	N ₂	N ₂
	1 hour	Air	Air
	5 minutes	N ₂	N ₂
Applied external resistance	<0.2 mOhm (to avoid potential difference between anode and cathode)		

for the GDL corrosion based on this test was approximately 10X of the fleet data. Using the AST for carbon corrosion, a new cathode GDL was implemented into the 2008 fleet leader. As shown in Figure 2, the new GDL showed at least a 5X improvement in durability over the 2006 fleet leader GDL at 0.55 V. This enabled the fleet durability to increase from 1,000-1,500 hours to 2,800 hours, at which point the 2008 fleet leader failed due to membrane failure. The failure was caused by mechanical fatigue due to hydration strain cycling at the air inlet. A membrane AST protocol, shown in Table 2, was developed to evaluate membrane resistance to hydration strain cycling. Scanning electron microscope images, shown in Figure 3, of the MEA returned from the field and the MEA tested using the lab AST protocol show that the failure mode was consistent. Figure 4 shows the open circuit voltage (OCV) pressure response with time as a function of temperature, load profile, and membrane type. The MEA in the 2011 fleet leader shows a >16X improvement in lifetime over the 2008 fleet leader MEA in the membrane AST protocol. As shown in

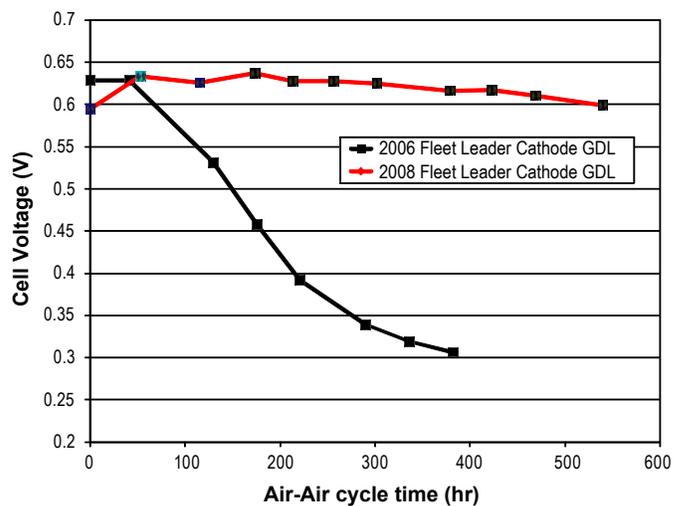

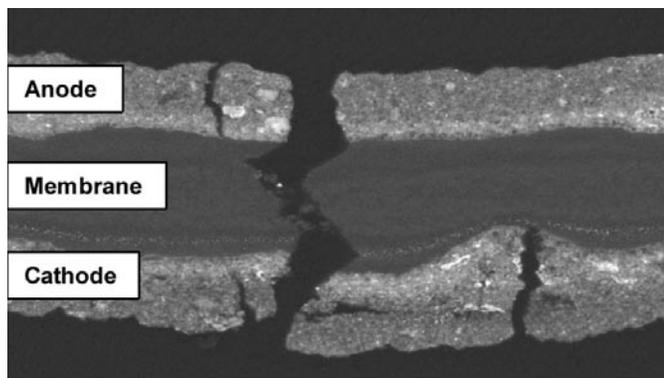

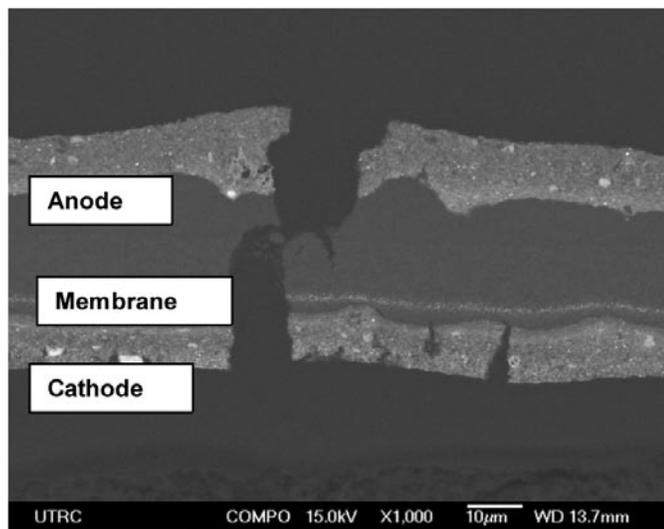

FIGURE 2. Effect of Cathode GDL on Performance Decay in Carbon Corrosion AST

Lab AST

FIGURE 3. Comparison of Microscopy Results for MEAs Run in the Field and in Lab ASTs

Figure 1, implementation of this MEA in the field resulted in an increase in field durability from 2,800 hours to over 9,600 hours, or 3.4 times higher. Based on the acceleration

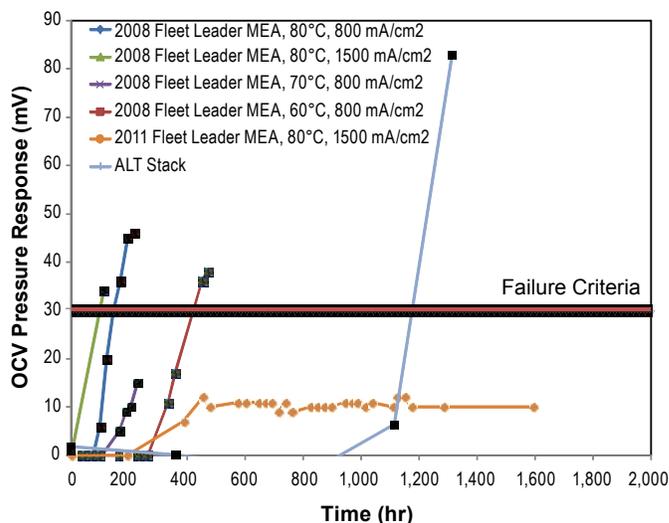

FIGURE 4. Summary of Open Circuit Voltage (OCV) Pressure Response for Single-Cell And Short Stack Membrane AST

factor measured in the lab AST, the MEA in the 2011 fleet leader is projected to last over 40,000 hours, if mechanical fatigue is still the controlling failure mode.

The effect of temperature and current density was also investigated. As shown in Figure 4, increasing the temperature from 60°C to 80°C decreased the lifetime by a factor of 4. Increasing the current density from 800 to 1,500 mA/cm² decreased the lifetime by about 20%. The ALT rig ran at 70°C, with a load cycling profile that mimics the fleet cycle. The ALT failed at 1,400 hours whereas the single cell, running at the same temperature, failed at 250 hours. The ALT cycle is much faster than the single-cell AST protocol. The membrane stress is lower in the ALT cycle because the rapid cycling does not allow the membrane water content to reach equilibrium. This is also apparent between the single cell run at 60°C and the field unit, which also runs at 60°C. The field unit lasted 2,800 hours, or seven times longer than the single cell, which only lasted 400 hours. These results indicate that the load cycle profile is as important to membrane durability, if not more, as the operating temperature. Table 3 summarizes the membrane AST results and membrane lifetime predictions.

TABLE 3. Summary of Membrane AST Data and Membrane Life Predictions

Membrane	Cyclic Protocol	Temperature	Estimated Time to Failure (hr)	Actual Time to Failure (hr)
2008 Fleet leader	Membrane AST	60°C	Not Applicable	425
2008 Fleet leader	Membrane AST	70°C	Not Applicable	~250
2008 Fleet leader	Membrane AST	80°C	Not Applicable	120
2011 Fleet leader	Membrane AST	80°C	Not Applicable	> 1,600
2008 Fleet leader	Field (ALT)	70°C	Not Applicable	1,400
2008 Fleet leader	Field	60°C	2,975	2,800
2011 Fleet leader	Field	60°C	45,000	> 9,500 (still running)

Conclusions and Future Directions

- Fleet/Real-World: UTC fleet performance and operating cycle analyses have been completed and reported. Teardown analyses of the real-world degraded components have been completed and reported.
- Lab-World: ASTs for platinum group metal decay, carbon support corrosion, membrane mechanical decay, and membrane chemical decay have been completed. Teardown analyses of the lab-world degraded components have been completed and reported.
- ALT: Testing has been completed.
- Next Step: Correlate real-world degradation to lab tested degradation for carbon corrosion of GDLs. Develop ex situ aging method for GDLs to isolate GDL oxidation effects from catalyst layer oxidation effects.

Project Start Date: October 2009
Project End Date: 2013

Fiscal Year (FY) 2011 Objectives

- Correlation of the component lifetimes measured in an accelerated stress test (AST) to “real-world” behavior of that component.
- Validation of existing component-specific ASTs for electrocatalysts, catalyst supports and membranes (mechanical and chemical degradation).
- Development of new ASTs for gas diffusion layers (GDLs) and bipolar plates.
- Coordinate effort with Fuel Cell Tech Team, Durability Working Group and US Fuel Cell Council (USFCC) Taskforce on Durability.

Technical Barriers

This project addresses the following technical barriers from the Fuel Cells section (3.4) of the Fuel Cell Technologies Program Multi-Year Research, Development and Demonstration Plan:

- (A) Durability
- (B) Cost

Technical Targets

Cost and durability are the major challenges to fuel cell commercialization. ASTs enable the rapid screening of fuel cell materials and are critical in meeting the long life times required for stationary and automotive environments. Moreover these ASTs can also help predict the lifetime of the various components in “real-world” applications.

Transportation Durability: 5,000 hours (with cycling)

- Estimated start/stop cycles: 17,000
- Estimated frozen cycles: 1,650
- Estimated load cycles: 1,200,000

Stationary Durability: 40,000 hours

- Survivability: Stationary -35°C to 40°C

Cost (\$25/kWe)

FY 2011 Accomplishments

- Performed all four DOE Fuel Cell Tech Team recommended ASTs on two different Ballard membrane electrode assemblies (MEAs) that were used in bus stacks.
- Failure analysis of MEAs and correlation between AST and real world data initiated.
- Initial breakdown analysis of two different types of bus stacks completed by Ballard.
- Modeling of voltage loss breakdown completed by LBNL.
- LANL validates the performance of Ion Power MEAs using different Tanaka catalysts and DuPont XL membranes.

Introduction

The durability of polymer electrolyte membrane (PEM) fuel cells is a major barrier to the commercialization of these systems for stationary and transportation power applications [1]. Commercial viability depends on improving the durability of fuel cell components to increase the system reliability and to reduce system lifetime costs by reducing the stack replacement frequency. The need for ASTs can be quickly understood given the target lives for fuel cell systems: 5,000 hours (~7 months) for automotive, and 40,000 hours (~4.6 years) for stationary systems. Thus testing methods that enable more rapid screening of individual components to determine their durability characteristics, such as off-line environmental testing, are needed for evaluating new

component durability in a reasonable turn-around time. This allows proposed improvements in a component to be evaluated rapidly and independently, subsequently allowing rapid advancement in PEM fuel cell durability. These tests are also crucial to developers in order to make sure that they do not sacrifice durability while making improvements in costs (e.g. lower platinum group metal [PGM] loading) and performance (e.g. thinner membrane or a GDL with better water management properties).

DOE has suggested AST protocols for use in evaluating materials, but only for the catalyst layer (electrocatalyst and support), and for the membrane [2,3]. The USFCC has also suggested AST protocols for the same materials [4]. While these protocols have concentrated on the catalyst, catalyst support and membrane materials, to date, no accelerated degradation protocols have been suggested for GDL materials or microporous layers (MPLs), bipolar plates or seals. In spite of recent advances in AST development, a main portion, which is deficient, is the quantitative correlation between the results of a given fuel cell AST, and the degradation rate or life in an operating fuel cell.

Approach

A main desired outcome of this task is the correlation of the component lifetimes measured in an AST to in situ behavior of that component in “real-world” situations. This requires testing of components via ASTs and in operating fuel cells, and delineating the various component contributions to the overall cell degradation. This will primarily be performed by using a simplified one-dimensional model that takes into account the different component contributions like membrane ionic conductivity, cathode catalyst layer kinetic losses and mass transport losses (catalyst layer and GDL) to the overall losses observed in operating cells [5]. This project will then attempt to correlate the performance losses observed due to a particular component in “real-world” situations with the degradation in AST metrics of that component. The correlation between AST and life data, if state-of-the-art materials are used, in essence gives one data point. Thus, for a reasonable correlation to be made, materials with different life spans will be utilized. This relies on the expertise of the suppliers as partners in the proposal. This work is also being coordinated with other funded projects examining durability through a DOE Durability Working Group, and through a USFCC task force on durability.

Results

The DOE Fuel Cell Technical Team recommended ASTs [6] were performed on two different MEA types (viz. P5 and HD6); that were used in buses operated in Hamburg (Germany), and in a bus module operated in the laboratory on an Orange Country Transit Authority cycle, respectively. The results from the potential cycling and high potential hold ASTs are illustrated in Figure 1a and b, respectively.

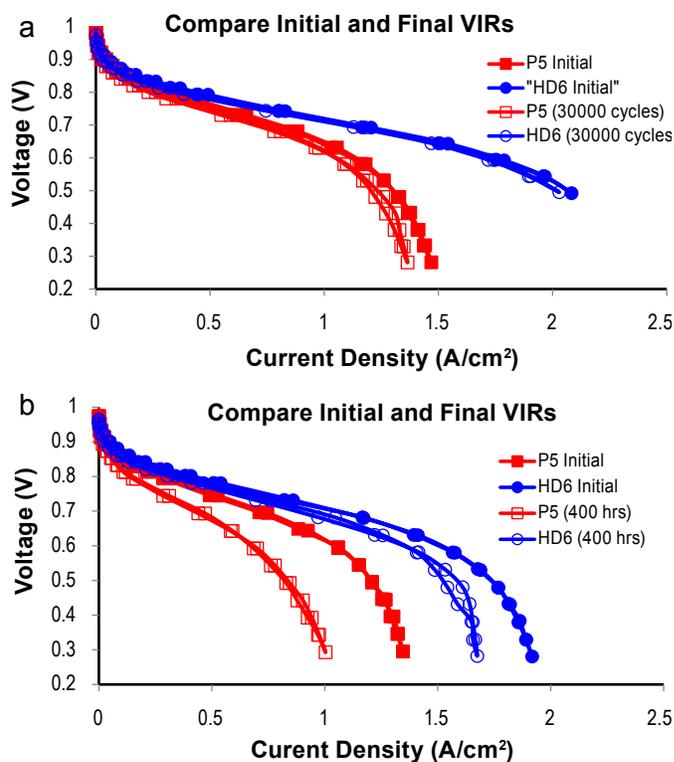

FIGURE 1. Performance of P5 and HD6 MEAs: a) before and after potential cycling and b) before and after high potential hold.

It is seen that the performance of the HD6 (circa 2007) MEA is significantly better than the performance of the P5 (circa 2002) MEA, especially in the mass transport region. Both these MEAs showed excellent durability of the Pt electrocatalyst as illustrated in Figure 1a by little performance loss after 30,000 potential cycles from 0.6 V to 1 V. Both MEAs met all performance targets including electrochemical surface area (ECSA) (<40% loss), mass activity (<40% loss) and voltage loss @ 0.8 A/cm² (<30 mV loss). On the other hand, the high potential hold AST resulted in significant degradation due to carbon corrosion especially in the P5 MEA (Figure 1b). While the P5 MEA failed to meet any of the DOE targets, the HD6 MEA met both the ECSA (<40% loss) and mass activity (<60% loss) targets, but failed to meet the voltage loss (@ 1.5 A/cm²) target (30 mV loss occurs at 175 hours while the target is 400 hours). This illustrates the fact that carbon corrosion leads to significant mass transport losses in addition to kinetic losses, and the voltage loss target is more relevant than the ECSA and mass activity targets for this particular AST.

The voltage loss breakdown in these cells as a function of ageing time was extracted by using a simple one-dimensional model to fit the polarization curves and impedance response of the single cells. This is illustrated in Figures 2a and b, for the potential cycling AST and high potential hold AST, respectively. During the potential cycling AST (Figure 2a) there is a small (<15 mV) increase in the voltage loss in the kinetic region while the

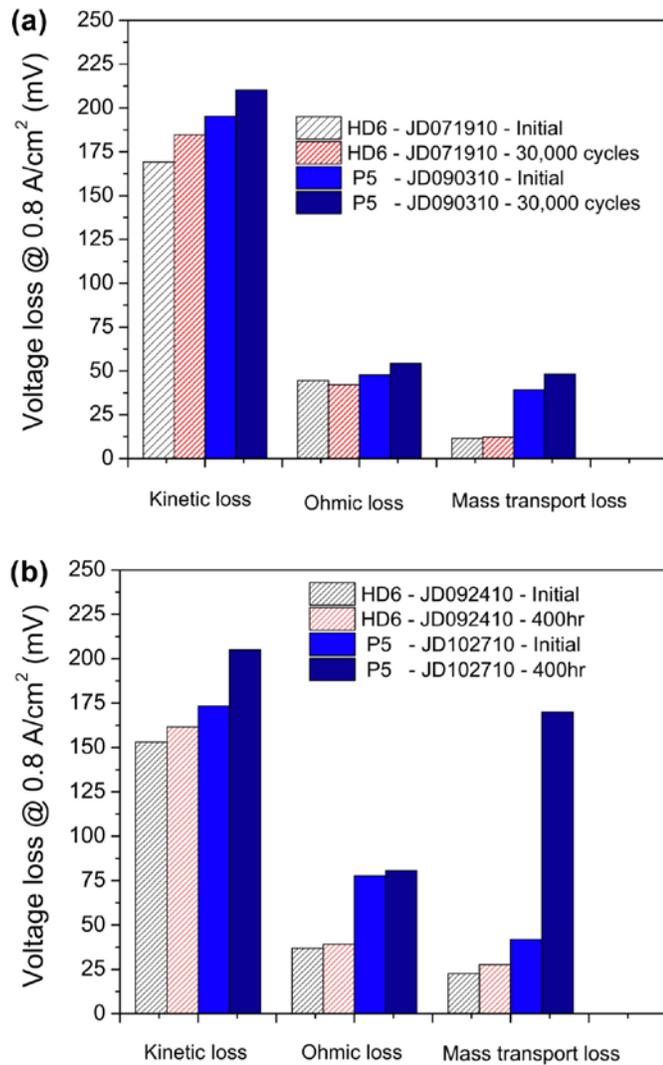

FIGURE 2. Voltage loss breakdown of the P5 and HD6 cells at 0.8 A/cm² obtained using a one-dimensional model: a) before and after potential cycling and b) before and after high potential hold.

ohmic and mass transport contributions remain virtually unchanged. This is consistent with the approx. 30% loss in ECSA observed for the two cells. During the 400 hours of high potential hold AST (Figure 2b) there is a much greater increase in both the kinetic (>25 mV loss) and mass transport losses (>125 mV loss) of the P5 cell when compared to the HD6 cell (<20 mV) at a constant current density of 0.8 A/cm². This is consistent with the more corrosion-resistant carbon used in the HD6 MEA. Failure analysis of these MEAs has been initiated and the Pt particle sizes and catalyst layer thicknesses will be measured and used to validate these ASTs with real world data from the bus fleets.

The performance of three P5 bus stacks operated in Hamburg (Germany) is illustrated in Figure 3a where all three stacks show a degradation rate of ≈30 μV/cell/hour. This is despite the fact that these stacks were exposed to

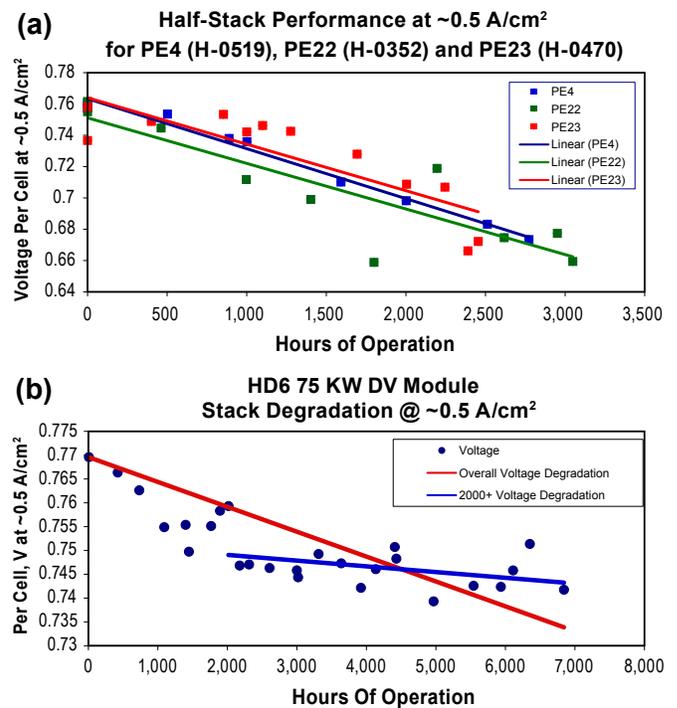

FIGURE 3. Voltage degradation observed in a) three P5 bus stacks operated in the field and b) one HD6 module operated under the Orange County Transit Authority drive cycle.

different stressors including temperature, relative humidity, voltages and air/air starts. The only tangible difference in the stressors was the lower number of air/air starts (263) in the PE23 stack which was associated with the lowest voltage degradation rate of 26.3 μV/cell/hour. The HD6 stack was operated in a laboratory under drive cycle conditions and showed an average degradation rate of 5.2 μV/cell/hour (Figure 3b). The data quality from this stack is better than the field data and clearly shows two different degradation rates with the 2,000 to 7,000 hour data showing only a degradation rate of 1.2 μV/cell/hour. The failure analysis from these stacks will be utilized to compare the field data with the AST data.

The open circuit voltage and fluorine emission rate in the effluent water during the membrane chemical degradation AST [6] test of the P5 and HD6 MEAs is shown in Figure 4a. Although the P5 MEA was 50 μm thick while the HD6 MEA was only 25 μm thick, the OCV of the P5 MEA degraded slightly faster than that of the HD6 MEA. It is also seen that the P5 MEA has a much larger fluorine emission rate than the HD6 cell, which is consistent with its worse performance in the field. This is illustrated in Figure 4b where the three P5 stacks all failed due to transfer leaks in <3,400 hours while the HD6 showed an increase in transfer leak rates only after 5,500 hours. The results of the AST test and field data will be modeling in the future and will be validated with the failure analysis from both the AST and bus stack MEAs.

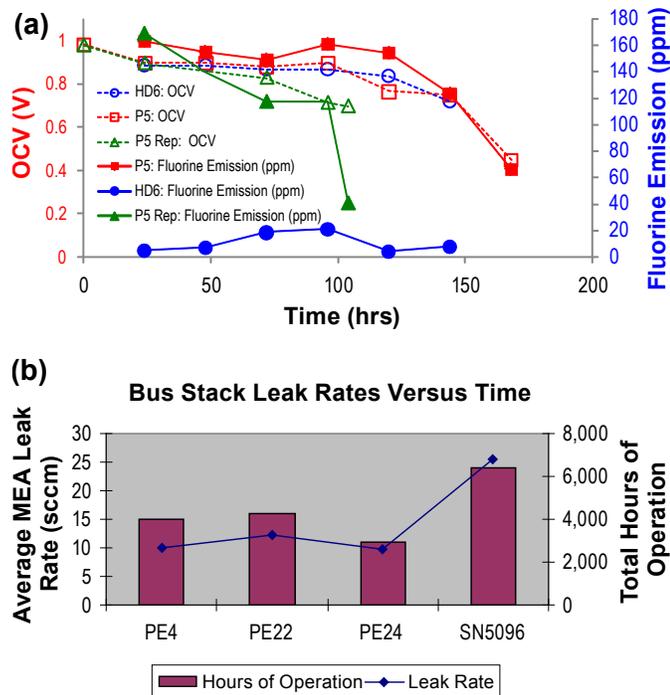

FIGURE 4. a) Fluorine content of the outlet water during an OCV AST test and b) transfer leak rates observed in P5 and HD6 stacks operated in buses.

Conclusions and Future Directions

The results from the P5 and HD6 AST tests are consistent with their performance observed in the field. While the potential cycling AST and relative humidity cycling ASTs showed little difference between the P5 and HD6 samples, the high potential and OCV hold ASTs highlighted the better performance of the HD6 MEAs. This will be correlated with the better performance in the field; both lower voltage degradation rates and delayed membrane transfer leaks. The field data is noisy due to recoverable performance losses and highly varying current demand imposed by the bus drive cycle. Moreover the effect of various stressors including temperature, voltage, relative humidity and air/air cycling complicates interpretation of field data. Failure analysis and voltage loss modeling work have been initiated and are expected to help correlate the AST data with the field data. The following specific work will be carried out in the coming years of this project in order to validate existing ASTs and recommend new ASTs.

AST Testing

- Perform ASTs on materials with differing durability supplied by Ion Power.
- Develop ASTs for ORNL-supplied bipolar plate materials and SGL-supplied GDLs/MPLs.

“Real-World” Testing

- Perform simulated automotive drive cycle testing on selected materials with differing durability.
- Study effect of operating conditions (Stressors) like temperature, pressure and relative humidity on drive cycle testing.

Characterization of Materials

- Ex situ characterization of catalyst particle size distribution, layer thickness, membrane thickness, and GDL hydrophobicity as a function of AST and “real-world” testing.

Correlation of AST to “Real-world” Data

- Statistical correlation of performance degradation with physical properties in both AST and “real-world” data.

Project Start Date: June 1, 2007

Project End Date: November 30, 2011

Fiscal Year (FY) 2011 Objectives

- Develop advanced physical models for water transport and generation, and conduct material and cell characterization experiments.
- Improve understanding of the effect of various cell component properties and structure on the gas and water transport in a proton exchange membrane (PEM) fuel cell.
- Encapsulate the developed models in a modeling and analysis tool for cell design and future application.
- Demonstrate improvements in water management in cells and short stacks.

Technical Barriers

This project addresses the following technical barriers from the Fuel Cells section of the Fuel Cell Technologies

Program Multi-Year Research, Development and Demonstration Plan:

- (A) Durability
- (D) Water Transport within Stack
- (E) System Thermal and Water Management
- (G) Start-up and Shut-down Time and Energy/Transient Operation

Technical Targets

This project addresses fundamental issues in water transport within the fuel cell stack. The resulting understanding will be applied toward the design of stack components and operating strategies that enable meeting the 2015 targets for transportation fuel cell stacks operating on direct hydrogen:

- Stack power density: 2,000 W/L
- Cold start-up time to 50% rated power @ 20°C: 5 secs
- Unassisted start from low temperature: -40°C

FY 2011 Accomplishments

- Predicted design and operating condition sensitivity observed in experimental measurements of wet pressure drop for two-phase flows in channels and gas diffusion layers (GDLs). Applied models to screen channel and cell design for effective water management.
- Integrated membrane water transport models with the computational fluid dynamics (CFD) two-phase cell scale models. Demonstrated improved agreement with measured current density profiles and qualitative agreement with trends in measured liquid water distribution.
- Developed a technique for reproducible, controllable hydrophobic treatment of GDL media that results in less water retention and fewer transport limitations than the treatments applied to commercially available materials.

Introduction

Water management in PEM fuel cells is challenging because of the inherent conflicts between: supplying adequate water to establish and maintain the membrane electrical conductivity, removing the water produced by the electrochemical reactions at the cathode, and uniformly distributing the gaseous reactants at catalyst surfaces near the membrane to effectively utilize these

costly catalysts. As power density of the cells increases, more water will be generated within the same cell volume. Therefore, increasing power density requirements will drive a greater need for design tools incorporating an improved understanding of how liquid water is transported within fuel cells. An additional barrier to widespread use of fuel cells for automotive power is the performance degradation caused when liquid water freezes within the cells. Optimizing water management to influence where the liquid water remains at shutdown is a promising path to improving cold starting capabilities and freeze-thaw reliability.

This project is intended to improve fundamental understanding of water transport within a PEM fuel cell, and capture that knowledge in design tools capable of assisting the industry to meet targets for increased power densities and improved cold-start performance. To achieve these objectives, the project is focused on developing predictive models for water transport in GDL materials, characterizing materials for model inputs and verification, implementing the resulting understanding in engineering design tools, and validating the resulting design tools against fuel cell performance data and in situ diagnostics of water distribution within operating fuel cells.

Approach

To meet the high level objectives of improving the fundamental understanding of water transport in PEMFCs and demonstrating improved performance, the team will integrate experimental characterization with model development and application. The initial focus of the experimental characterization was on measuring relevant physical and transport properties of the GDL materials typically placed between the catalyst and reactant flow channels. Diagnostic and characterization studies have transitioned to water and two-phase (water and air) fluid transport properties of GDL materials and analysis of water transport across material interfaces and in fuel cell channels. The related modeling studies follow a similar progression, with initial emphasis on microscale simulations of single fluid and two-phase transport within GDL materials. The simulations allow us to analyze key effects such as the impact of the microstructure and surface treatment of the solids within porous GDL materials on the two-phase water and gas transport. The knowledge gained from the materials characterization and microscale simulations is being used to develop models suitable for incorporation into an engineering design tool for fuel cell scale analysis of reactant and water transport coupled with power generation. The verification of these models and the resulting design tool will be accomplished by comparing predicted and measured effects of material and operating conditions on cell performance and water distribution within the cell. Applying our models to screen and improve water management strategies, then testing the resulting concepts in prototype fuel cells, will further demonstrate our improved fundamental understanding and validate the resulting design tools.

Results

In this fourth year of research, the emphasis has been on validation of the developed simulation tools and models for fuel cell performance and water transport during operation, application of the modeling tools to evaluate water management and related effects for varying designs and operating conditions, and further development and testing of approaches to improve water management.

The model solution approaches for two-phase flow of liquid water and gases were improved to better address flow across the interfaces between the porous GDLs and the gas channels. CFDRRC then simulated two-phase pressure drop experimental studies performed at Ballard, in order to evaluate the current status of the models. This study was intended to gauge the impact of improvements in both the fluid dynamics algorithms, and better understanding of appropriate model setup and property values. The model setup was improved by slightly refining the computational grid, improving the grid node distribution for more uniform computational cell aspect ratios and smoother transitions from fine to coarse regions. Model implementation and solution algorithm improvements for the energy equation could also affect these results, since the Ideal Gas Law was used for gas phase density and the energy equation solution and convergence affect the gas phase density and fluid dynamics. The model was tested against measured pressure drops in the Generation 2 experimental fixture at Ballard, which is more repeatable than the original apparatus due to better sealing. In these experiments, water was injected into a GDL at a constant flow rate mimicking liquid water formation and transport into the channels during cell operation. The air flow rate through the channel was fixed, and pressure drops were measured as a function of time and flow rates. The models predicted the trends in wet pressure drop with operating conditions, Figure 1a, which we were able to capture with earlier models. These models also demonstrated the correct trend for the wet pressure drop response to design variations, particularly changing the channel aspect ratio, Figure 1b, unlike the earlier models.

Ballard has continued to evaluate and apply the simulation tools for a number of cell designs. The numerical stability and accuracy improvements over the last year have enabled an increasing use of computational studies of liquid water effects in non-operational single cells and stacks. The single-channel studies at Ballard demonstrated that the models can accumulate sufficient water in channels to reproduce experimentally observed wet pressure drops. Ballard has also applied the models to two-phase flow in fuel cell stacks, investigating manifold design and flow mal-distribution among as many as 28 parallel channels. The qualitative trends observed in the stack studies are also consistent with experimental observation, particularly the excess air flow required to prevent liquid water from affecting performance. In both the models and experimental stack characterization, it is air stoichiometry and performance in 'end' channels that typically suffer

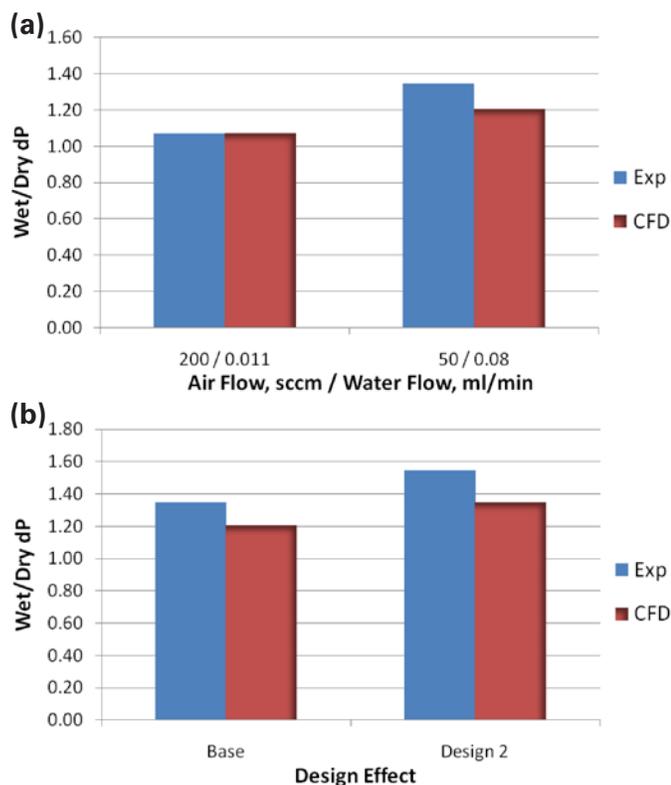

FIGURE 1. Comparison of Predicted and Measured Two-Phase Pressure Drops in Base Channel Design (a) as a Function of Operating Conditions, and (b) at Low Stoichiometry (50/0.08 Flows) Conditions as Function of Channel Design

the greatest reduction in air flow when liquid water in the channels affects performance.

The improvement and evaluation of the two-phase models integrated with electrochemistry, heat transfer, phase change, and water sorption and transport within the membrane has continued. One key model improvement over the past year is improved coupling with the widely used Springer model for transport of water within the membrane [1]. The example experimental data and simulation results presented here are for a three-dimensional model of an operational Ballard MK902 cell, with the simulations including the Springer model. Although this cell has been used previously for model evaluation because of the detailed diagnostic data and past modeling results available for comparison, in this case the experiments were performed at Ballard during the past year. The base operating conditions were cathode stoichiometry 1.8, anode stoichiometry 1.6; relative humidities of the inlet streams cathode 87%, anode 46%; cathode oxidant inlet temperature 65°C, fuel inlet temperature 75°C; and pressure 3 atmospheres in both channels. Model input properties were primarily from historical analysis and fitting at Ballard and CFDRC, with GDL properties updated based on our earlier characterization and a modified capillary pressure function extracted from the measurements of Sole [2]. A residual

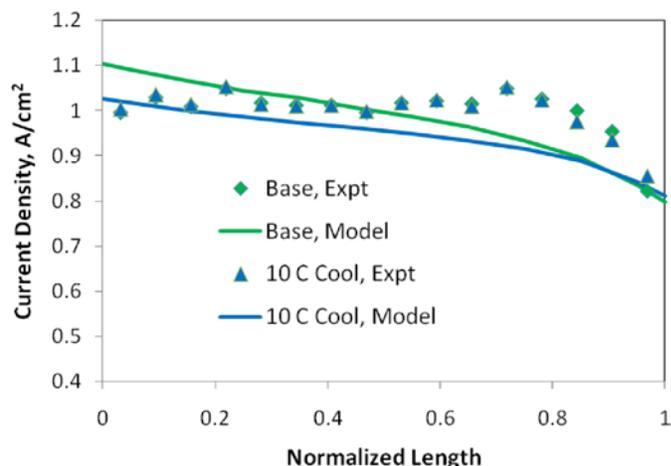

FIGURE 2. Comparison of Predicted and Measured Current Density Profiles for Base and 10°C Cooler Operating Conditions at 1 A/cm²

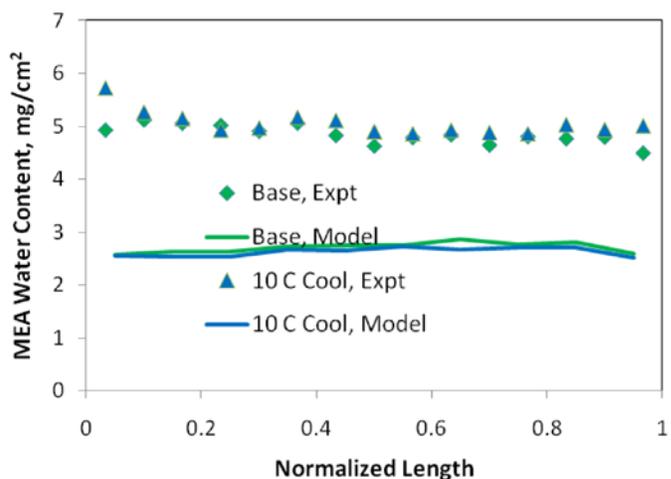

FIGURE 3. Comparison of Predicted and Measured MEA Water Content Profiles for Base and 10°C Cooler Operating Conditions at 1 A/cm²

saturation of 0.2 was used to obtain the normalized liquid water saturation. Comparison of the predicted and measured current density profiles for the base operating conditions and for 10°C cooler operation, expected to result in additional liquid water, is shown in Figure 2. The experimental data has a large constant current density region along the length of the cell, as opposed to the model results which indicate decreasing current density in the direction of cathode gas flow. The membrane electrode assembly (MEA) water content profiles are more uniform with position in the cell, as shown in Figure 3. Although the prediction is approximately half the measured water mass, the model is capturing the trend of a relatively uniform distribution and little variation of water content between the two operating conditions.

Techverse developed an electrophoresis-based approach for impregnating GDL materials with Teflon[®]. Various forms

of this treatment are widely used to make the materials hydrophobic, i.e. non-wetting. The samples prepared with the electrophoresis technique consistently have a higher breakthrough pressure than commercially available papers with equivalent Teflon® loading. The materials treated by the developed electrophoresis approach also consistently have a lower residual saturation, indicating a smaller amount of water trapped inside the media. The air permeability of partially saturated samples tends to show greater permeability and less water saturation for a given air flow rate in the Techverse samples. All of these characterization results are consistent with the microscopic imaging analysis, Figure 4, which shows a more uniform Teflon® distribution over the fibers of the GDL in the Techverse samples generated by electrophoresis than in the samples generated by typical commercial production techniques. BCS Fuel Cells prepared fuel cells from the Techverse treated GDLs and measured cell performance. Although the initial tests demonstrated slightly higher electrical contact resistance between the GDL and landings than the control materials, performance improved relative to the control samples

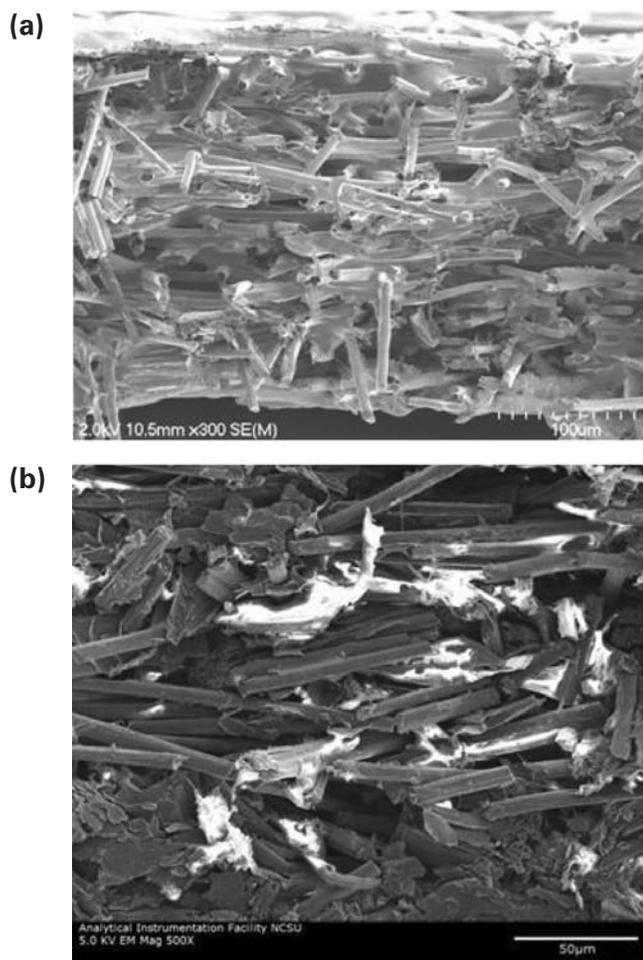

FIGURE 4. Micrographs of (a) Electrophoresis Process Teflonated GDL Material, and (b) Commercially Available Teflonated GDL Material

as current density was increased. A method for adding a micro-porous layer to the GDLs must be developed to more thoroughly evaluate the Techverse materials, and that process is currently under development.

Conclusions and Future Directions

During the past year, we have demonstrated prediction of liquid water effects for two-phase flows in fuel cell microchannels and begun application to water management issues in cell and stack level component design. A promising materials modification has been developed, increasing the hydrophobicity of GDL materials to reduce water retention and related decreases in cell performance. Specific accomplishments for the past year include:

- Predicted design and operating condition sensitivity observed in experimental measurements of wet pressure drop for two-phase flows in channels and GDLs, applied models to screen channel and cell design for effective water management.
- Integrated membrane water transport models with the CFD two-phase cell scale models, demonstrated improved agreement with measured current density profiles and qualitative agreement with trends in measured liquid water distribution.
- Developed a technique for reproducible, controllable hydrophobic treatment of GDL media that results in less water retention and fewer transport limitations than the treatments applied to commercially available materials.

The key activities planned for the balance of the project are to complete validation of the water transport models based on data gathered during optimization studies, and to make recommendations for water management improvement including operating strategies and GDL materials modifications.

Project Start Date: October 2009
Project End Date: September 2012

Objectives

- Develop and validate a two-phase, three-dimensional (3-D) transport model for simulating proton exchange membrane fuel cell (PEMFC) performance under a wide range of operating conditions.
- Apply the validated PEMFC model to improve fundamental understanding of key phenomena involved and to identify performance-limiting processes and develop recommendations for improvements.

Technical Barriers

This project addresses the following technical barriers from the Fuel Cells section of the Fuel Cell Technologies Program Multi-Year Research, Development and Demonstration Plan:

- (C) Performance
- (D) Water Transport within the Stack

Technical Targets

Since the validated PEMFC model developed in this project can be employed to improve and optimize the design and operation of PEMFCs, insights gained from applying the model will help meet the following technical targets:

- Performance: 650 W/L or 50% energy efficiency for automotive applications; 40% electrical energy efficiency for stationary applications.
- Cost: \$30/kW for automotive applications and \$750/kW for stationary applications.

Fiscal Year (FY) 2011 Accomplishments

- Developed a 3-D, fully two-phase, single-cell model and completed the Year 2 model-development milestone, “Develop a 3-D, fully two-phase, single-cell PEM fuel cell model”.
- Demonstrated the capabilities of the present fully two-phase single-cell model in case studies, including simulating a PEMFC with a complex Chevron flowfield.
- Made significant progress in model validation using polarization and current distribution data obtained by LANL using a 10x10 segmented cell.
- Developed and demonstrated a non-isothermal pore-network model for simulating water and thermal transport at the pore level.
- Performed 3-D computational fluid dynamics (CFD) simulation to verify the analytical droplet-detachment model developed previously.
- Carried out simplified calculations to estimate water flux at the gas diffusion layer (GDL)/channel interface.
- Investigated effect of cell segmenting on current-distribution measurements and developed guidelines on how a cell should be segmented to minimize the side effect of cell segmenting.
- Obtained current distribution maps experimentally using LANL’s 10x10 segmented cell, and completed Year 2 experimental milestone, “Measure 10x10 current distribution performance data for model validation for four different operating conditions (relative humidity [RH] =25%, 50%, 75%, 100%)”.
- “Polarization areas” with upper and lower bounds were obtained experimentally. Simultaneous current and temperature measurements were also obtained using mapping tool.

Introduction

As PEMFC technology matures and enters the stage of commercialization such that the industry strives to achieve desired performance and durability and reduce costs, process design and optimization become increasingly important and indeed critical. Modeling and simulation can provide guidance in PEMFC design and optimization and thus help accelerate the commercialization of PEMFC technology. Despite tremendous research efforts and a large number of models published in the literature (see Chen et al. [1] and references therein), a comprehensive, multi-physics computer model suitable for practical use by PEMFC engineers and designers, particularly in transportation and stationary applications, is still lacking.

The objectives of this project are twofold: 1) to develop and validate a two-phase, 3-D transport model for simulating PEMFC performance under a wide range of operating conditions; and 2) to apply the validated PEMFC model to identify performance-limiting phenomena or processes and develop recommendations for improvements so as to accelerate the commercialization of fuel cell technology. To achieve these two objectives, a multi-institutional and interdisciplinary team with significant experience in modeling PEMFCs and in measuring model-input parameters and model-validation data has been assembled. This team is led by SNL; it includes two other national laboratories (LANL and LBNL), a university (PSU), and two PEMFC manufacturers (Nissan and Ballard). In addition to developing and validating a two-phase, 3-D PEMFC model, we are also coupling the PEMFC model with DAKOTA [2] (a software toolkit for design, optimization, and uncertainty quantification developed by SNL) in order to create a computational capability that can be employed for PEMFC design and optimization. This report documents technical progress made in the project during FY 2011.

Approach

Our approach is both computational and experimental. We first develop a two-phase, 3-D, transport model for simulating PEMFC performance under a wide range of operating conditions by integrating the detailed component sub-models; FLUENT (a commercial CFD code) is employed as the basic computational platform. We then validate our PEMFC model in a staged approach using experimental data available from the literature and those generated by team members. Lastly, we plan to apply the validated PEMFC model to identify performance-limiting phenomena or processes and develop recommendations for improvements. As mentioned previously, we have assembled a team of leading experts in PEMFC modeling as well as in physical, electrochemical and transport property characterization, and cell diagnostics via segmented cell measurements and neutron imaging – this means that our project team is highly qualified and in an excellent position to carry out the project.

Results

Due to space limitation, only sample results are provided here. Figure 1 compares the partially two-phase model (in which flow in the channels is considered as single phase) with the fully two-phase model (in which flow in the channels is treated as two phase) by displaying along-channel contours computed by the two different models. Operating parameters are listed in Table 1, and detailed cell geometry and material (transport and physical) properties are provided in Table 1 of reference [1]. As expected, the partially two-phase model is not capable of capturing the two-phase behavior in the channels but the fully two-phase model does. Near the outlet of the cathode channel, liquid water is seen to be transported first from the channel to the GDL and then to the anode side due to drier anode inlet (note: counter flow is employed in the present work). In addition, the single-phase channel model predicts a dry-wet-dry transition pattern in the GDL-catalyst layer region whereas such wet-dry transition does not appear with the fully two-phase model since it predicts much more water in the channel.

Figure 2 shows liquid-saturation contours at the GFC (gas flow channel)/GDL interface as computed by the fully two-phase model for three anode/cathode inlet RH values: 42.5%, 66.4%, and 91.6%. Operating parameters are listed

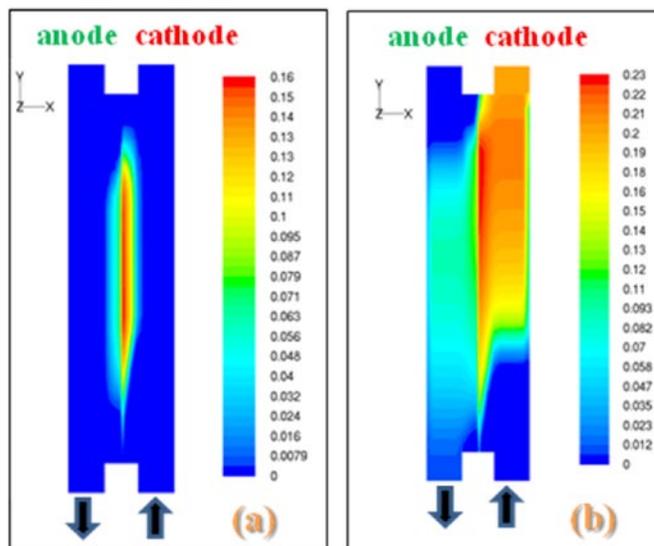

FIGURE 1. Partially two-phase model vs. fully two-phase model – computed liquid saturation contours on the symmetric plane: (a) partially two-phase model; and (b) fully two-phase model.

TABLE 1. Operating Conditions for the Base Case

Current density	0.8 A/cm ²	Anode stoichiometric flow ratio	1.8
Cell temperature	80°C	Cathode stoichiometric flow ratio	2.0
Anode/cathode back pressure	200 kPa	Anode/cathode RH	66.4%

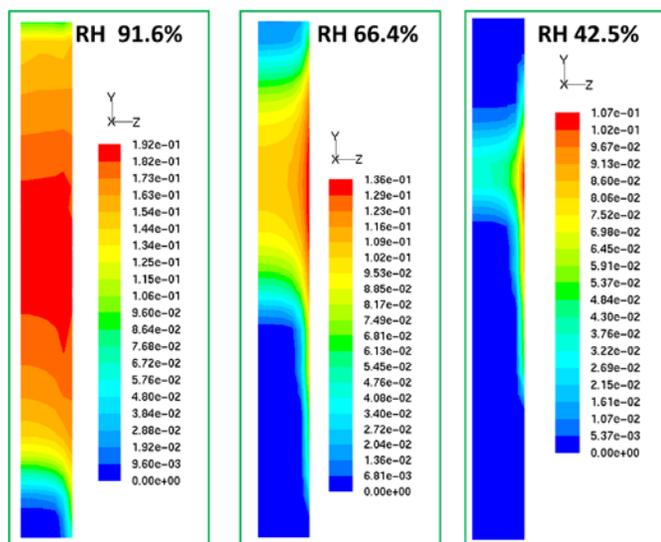

FIGURE 2. Computed liquid-saturation contours at the cathode GFC/GDL interface by the fully two-phase model – effect of inlet RH.

in Table 1. Clearly, more liquid water is accumulated in the cathode gas flow channel (GFC) as anode/cathode inlet RH is raised. Moreover, liquid saturation near the cathode outlet increases with increasing inlet RH, indicating that water transport from cathode to anode decreases.

Figure 3 displays computed liquid-saturation contours at the GFC/GDL interface for two current densities: 0.2 A/cm² and 1.5 A/cm². Operating parameters are listed in Table 1. It can be seen from Figure 3 that cathode GFC has more liquid water at low current densities than at high current densities – this most likely is due to that sufficiently large drag force is required to remove liquid water from the GFC. Of the four cases (0.1, 0.2, 1.0, and 1.5 A/cm²) studied, cathode GFC has the most liquid water at current density of 0.2 A/cm². Lastly, as current density is reduced, it was found that the wet region in the cathode GFC enlarges gradually in both downstream and upstream, due to the smaller drag force of gas flow.

In Table 2, the current-density distribution computed using the fully two-phase model are compared with that measured using LANL’s 10x10 segmented cell. The operating conditions are: 80°C, 50% RH, and 0.4 A/cm², and detailed cell geometry and material (transport and physical) properties are provided in Table 1 of reference [1]. From the numbers presented in Table 2, we can conclude that the agreement between computed and measured current density distribution is good with the root-mean-square error being less than 11.3% .

Lastly, a comparison between measured and computed polarization curves is presented in Figure 4, which shows good agreement. Geometric parameters, material (transport and physical) properties, and operating conditions for this study are presented in Table 1 of reference [1]. Further details on this model validation study is provided by Carnes et al. [3].

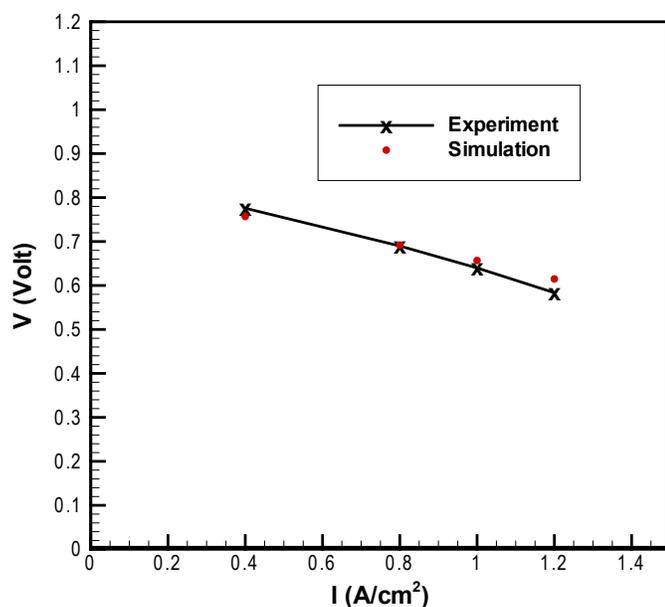

FIGURE 4. Model validation: comparison of measured and computed polarization curves.

Summary and Conclusions

- A 3-D, fully two-phase, single-cell model for simulating PEMFC performance was developed and the milestone of developing a 3-D, fully two-phase, single-cell model was met.
- Significant progress has been made in model validation using polarization and current distribution data obtained by LANL using a 10×10 segmented cell.
- Current distribution maps were obtained experimentally using LANL's 10×10 segmented cell, and the Year 2 experimental milestone, "Measure 10×10 current distribution performance data for model validation for four different operating conditions (RH = 25%, 50%, 75%, 100%) was met.

Future Directions

- Complete model validation in the single-phase and partially two-phase regimes using LANL current-distribution data from segmented cell experiments, and test data from Ballard and Nissan.
- Complete sub-model and algorithm development, and numerical implementation.
- Develop a 3-D, two-phase, short-stack PEMFC model.
- Obtain water profiles in the through-plane using neutron radiography setup at the National Institute of Standard and Technology (NIST).
- Perform model validation in the fully two-phase regimes using neutron imaging data obtained by LANL at NIST, and test data from Nissan and Ballard.

- University of South Carolina (USC), Columbia, SC

Project Start Date: October 5, 2009

Project End Date: October 4, 2012

Fiscal Year (FY) 2011 Objectives

- Design of fuel cell components targeting specific transport properties:
 - Synthesis of block copolymers.
 - Design of flow fields and gas diffusion layers (GDLs).
- Determination of bulk membrane properties:
 - Water uptake and diffusivity.
 - Gas permeability.
 - Electro-osmotic drag.
- Transient, three-dimensional modeling of fuel cell operation.

Technical Barriers

This project addresses the following technical barriers from the Fuel Cells section of the Fuel Cell Technologies Program Multi-Year Research, Development and Demonstration Plan:

- (C) Performance
- (D) Water Transport within the Stack
- (E) System Thermal and Water Management
- (G) Start-up and Shut-down Time and Energy/Transient Operation

Technical Targets

The goals of this project are not to reach specific technical targets put forth by the DOE (i.e., target catalyst loading, target cost per kilowatt). Instead, this project aims to develop fuel cell components (i.e., membranes, GDLs, bipolar plates and flow fields) that possess specific properties (i.e., water transport and conductivity). A computational fluid dynamics model will then be developed to elucidate the effect of certain parameters on these specific properties (i.e., the effect of membrane type and thickness on membrane water transport). Ultimately, the model will be used to determine sensitivity of fuel cell performance to component properties to determine limiting components and guide research.

FY 2011 Accomplishments

- Developed a second system to measure dynamic water uptake and diffusivity of membranes in addition to previously developed static diffusivity apparatus. Water isotherms and diffusivities of various membranes including Nafion® 112, Nafion® 1110 and NRE 212 have been obtained using both systems. We conclusively have shown that membrane interfacial resistance to water transport is negligible.
- Designed segmented cells to quantify fuel cell voltage vs. current at different points along the active area and tested the concept in common 50 cm² hardware with negligible change in performance.
- Characterized customized GDLs in terms of scanning electron microscopy (SEM) microstructure and fuel cell performance and correlated them to various pore structure, tortuosity and hydrophobicity.
- Developed the second iteration of fuel cell flow fields with thin metallic sheets to better correlate with automotive cells. Have also developed segmented cells for these plates.
- Modeled the effect of altering polymer electrolyte membrane (PEM) diffusivity to 6x and 1/6x that of PFSA membranes on fuel cell performance and water distribution.

- Synthesized block polysulfone ether polymers-bi phenyl sulfone (BPSH-BPS) multiblock copolymers with higher block lengths and self-assembled nanostructures, which provide designing guidelines for PEMs and will be used for model tests.

Introduction

Many fuel cell component properties that influence water transport and thermal management are not well-understood [1,2]. A better understanding of how water transport and thermal management can be controlled would represent a significant step forward in meeting the DOE's stated 2015 targets. This project aims for a better understanding of water transport and thermal management by tailoring fuel cell components to exhibit specific transport properties. These transport properties will then be modeled, which will enable the prediction of the effect of changing component parameters on transport properties.

Approach

This project seeks to develop fuel cell components possessing specific transport properties. Membranes will be developed to achieve different ratios of water transport and conductivity. Bulk membrane properties (i.e., diffusivity, water uptake, conductivity) will be evaluated and modeled. GDLs and bipolar plates and flow fields will be developed, and also tailored to achieve specific differences in porosity, tortuosity and hydrophobicity. The fuel cell performance will be evaluated using these components. The model will be used to predict the effect changing component parameters (i.e., changing membrane type and thickness, changing flow field configuration) will have on component transport properties and fuel cell performance.

Results

Membrane Synthesis and Nano-Scale Properties

A dynamic water uptake and diffusivity measurement apparatus was developed. This is a further advancement beyond the static water uptake system made in fiscal year 2010. Dynamic water uptake is of interest for it determines rate of water transport in a changing water activity environment. When the relative humidity (RH) changes in the fuel cell, the water content of the membrane changes, and subsequently the membrane must swell or shrink to accommodate this change. There is debate amongst the fuel cell community if this necessary mechanical work (for expanding a membrane to increase water content) slows water transport compared to a static gradient, where water content is not changing across the membrane thickness. For the dynamic system, a small chamber with a membrane strip (2.2 cm × 0.5 cm) is placed in line with an ante-chamber.

Both chambers are evacuated. The ante-chamber is then filled with water vapor to a selected RH. A valve between the membrane and ante-chamber is then opened. The two chambers equilibrate immediately, then the pressure begins to drop as the membrane absorbs water. By measuring the kinetics of this pressure drop we can determine the diffusivity of the membrane under those conditions. The pressure in the ante-chamber is then increased and the experiment is repeated to determine diffusivity at the next RH level. Similarly the experiment can be performed for desorption. Finally, by knowing the volume of both chambers, the absolute amount of water absorbed can be determined to obtain the water vapor isotherm.

The diffusion coefficients for NRE 212 at 80°C were measured over a range of membrane water contents by absorption and desorption experiments. These dynamically-measured diffusion coefficients are plotted against the diffusion coefficients measured via steady-state analysis in Figure 1, where the lines on the data points represent the 95% confidence intervals. The diffusion coefficients are nearly identical, regardless of the type of experiment performed (i.e., absorption, desorption or steady-state). The inserted figure shows water uptake isotherms for the Nafion[®] 1110 and NRE 212 membrane. The solid curve in the figure is the previously-reported water uptake isotherm described by an empirical equation in the reference [3], which is compared with the dotted line obtained by measuring the weight change of the membrane in contact with water vapor. These two isotherms are very nearly identical, indicating that the dynamic uptake experiments are an alternative valid approach to measuring steady-state water uptake.

To determine the current distribution, a current distribution plate made of a thin copper layer attached to a Kapton film was developed as shown in Figure 2. The plate rests between the flow field and the diffusion media and

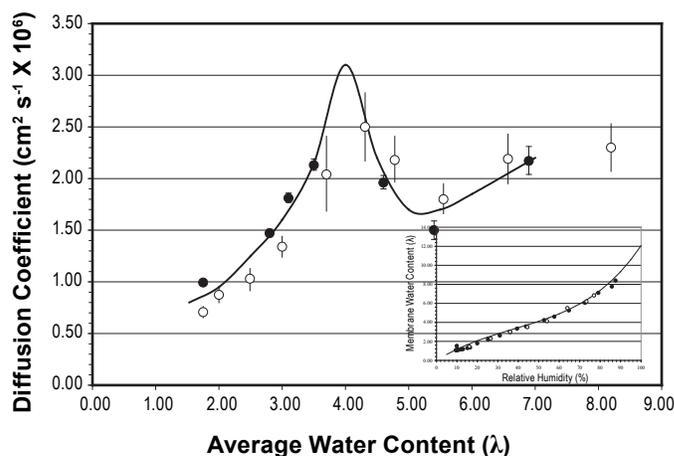

FIGURE 1. Diffusion coefficients measured from (—) steady-state data; (●) dynamic water uptake; (○) dynamic water desorption by Nafion[®] 212 at 80°C. The inserted figure shows water uptake isotherms for the Nafion[®] 1110 and NRE 212 membrane.

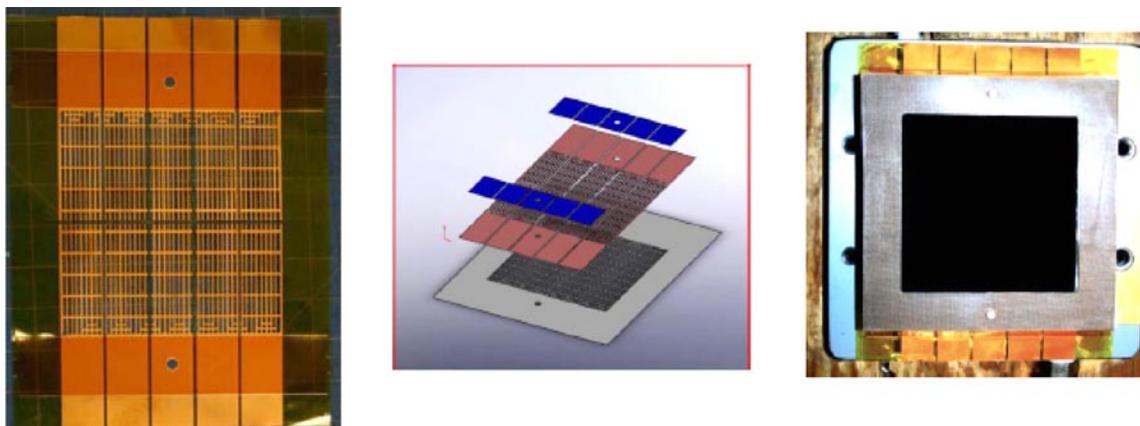

FIGURE 2. A current distribution plate made of Kapton film attached with a thin copper layer. The plate rests between the flow field and the diffusion media and the concept was tested in 50 cm² regular fuel cell hardware.

the concept was tested in 50 cm² regular fuel cell hardware. The current distribution board adds only 7.5 mOhms-cm². The performance discrepancy before and after the current distribution plate addition is negligible. A new flow field with thin metallic sheets was designed and fabricated since heat transport and fluid cooled plates can have a large impact on the current distribution. This thin plate design with central cooling is being used by automotive manufacturers for fuel cell plates and it is essential to mimic the diffusion media/flow field interface as closely as possible.

GDLs with various pore structure, tortuosity and hydrophobicity were custom fabricated by BASF and Ballard Materials. The matrix of GDLs is shown Table 1. They were characterized in terms of microstructure, pore size distribution, and fuel cell performance. The fibers constitute the bare substrate when there is no wet proofing. In contrast, materials fill in between fibers in the GDLs with 10% or 40% wet proofing. For the GDLs with 10% and 40% microporous layer (MPL), SEM images reveal a merge between the substrate and the MPL instead of a well defined and a clear boundary. The effect of wet proofing, MPL and porosity on the MacMullin Number (ratio of transport resistance with the diffusion media compared to without) was investigated. Increasing the wet proofing decreases the porosity of the substrate layer. Consequently, a higher flow resistance is expected as porosity decreases and tortuosity increases. However, the addition of the

TABLE 1. Matrix for Customized GDLs

GD	Layers & % Hydrophobicity	Image #	Avg. Porosity
1	Substrate Only (No wet proofing)	a	0.80
2	Substrate Only (10%)	b, d	0.78
3	Substrate (10%) + MPL (10%)	c	0.75
4	Substrate (10%) + MPL (40%)	f	0.74
5	Substrate Only (40%)	c, g	0.69
6	Substrate (40%) + MPL (10%)	h	0.68
7	Substrate (40%) + MPL (40%)	i	0.69

MPL decreases the MacMullin number. This effect could be related to the different wet proofing treatments of the substrate and the MPL, which can cause an additional driving force in the liquid through the pores during the experiments. Even when the treated surfaces have the same wet proofing percentage the actual contact angle in each surface could be different.

PEM diffusivity in the model was altered to 6x and 1/6x that of PFSA membranes to investigate the effect of diffusivity on performance. Figure 3 shows simulated current density distribution on the MEA surface at three water diffusivities and average current density of 0.6 A/cm² with (a) 75%/25% RH and (b) 25%/25% RH (anode/cathode, co-flow). It is interesting that for both anode humidity conditions, increasing diffusivity gives the most uniformity in current density distribution and 1/6 Dw shows the most non-uniformity in distribution. Also, increasing diffusivity leads to the largest improvement in the dry anode case. This is not surprising as the water needs to diffuse to the anode to counter electro-osmotic drag. The block copolymers being developed are expected to have a very different diffusivity than Nafion[®], and will be used to confirm these predictions.

BPSH-BPS multiblock copolymers with higher block lengths and self assembled nanostructures have been synthesized, which provide designing guidelines for PEMs in term of structure, chemistry and phase separation and will be used for model tests. A cluster of multi-block copolymers comprised of hydrophilic telechelic BPS-100 oligomers and 6FPAEB oligomers, both of which vary in molecular weights (i.e., 7k-7k, 14k-14k, 15k-15k, 10k-18k) have been prepared. They clearly demonstrate different nano-phase separated structures based on transmission electron microscope images. Beyond chemistry and block length, thermal history also influences the PEM properties. Figure 4 shows measured conductivities of 6FPAEB-BPSH100 14k-14k at different annealing temperatures as a comparison to Nafion[®] 212 membrane. It can be seen that annealing at

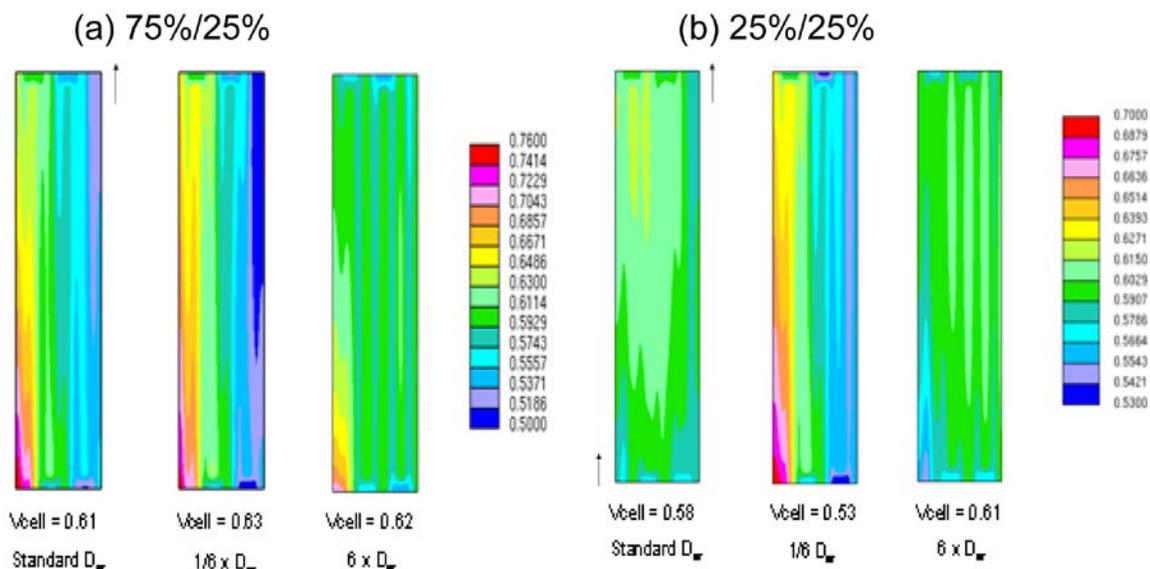

FIGURE 3. Simulated current density distribution on MEA surface at three water diffusivities and average current density of 0.6 A/cm^2 : (a) 75%/25% RH and (b) 25%/25%RH, anode/cathode for a co-flow configuration.

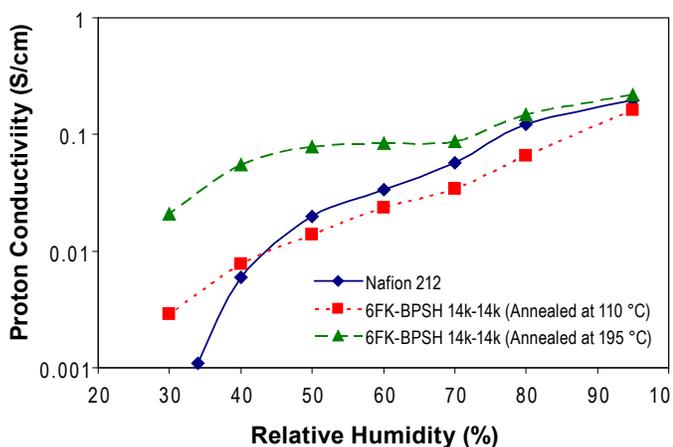

FIGURE 4. Measured conductivities of 6FPAEB-BPSH100 14k-14k at different annealing temperatures as a comparison with Nafion® 212 membrane.

195°C tremendously improves the membrane conductivity in contrast to that at 110°C.

Conclusions and Future Directions

- Many new analytical techniques were developed for characterizing water transport:
 - No interfacial resistance found for Nafion®
 - Static and dynamic diffusivity found to be the same
 - Techniques will be made widely available to the fuel cell research community
- Widely varied PEMs and diffusion media will allow us to model the important parameters of each.

- A base model has been developed and used to describe various performance results with different diffusion media.
- In FY 2012, we plan to: Extend characterizations to alternative materials.
- Extend testing to more realistic automotive platform.
- Down-select alternative polymers and generate larger, consistent materials.
- Confirm model with performance, current distribution and water collection results.
- Use model to determine performance sensitivity to build materials, suggest focus areas.

Project Start Date: June 1, 2010

Project End Date: May 31, 2013

Fiscal Year (FY) 2011 Objectives

- Characterize saturated relationships in state-of-the-art fuel cell materials.
- Obtain a comprehensive down-the-channel validation data set for a baseline and auto-competitive material set.
- Optimize component models to output bulk and interfacial transport resistances.
- Demonstrate integrated transport resistances with a one plus one-dimension (1+1D) fuel cell model solved along a straight gas flow path.
- Identify critical parameters for low-cost material development.

Technical Barriers

This project addresses the following technical barriers from the Fuel Cells section of the Fuel Cell Technologies

Program Multi-Year Research, Development and Demonstration Plan:

- (B) Cost
- (C) Performance
- (D) Water Transport within the Stack

Technical Targets

This project supports fundamental studies of fluid, proton and electron transport with focus on saturated operating conditions. Insights gained from these studies are being used to develop modeling tools that capture fundamental transport physics under single and two-phase conditions. This project addresses the expected outcomes from Topic 4a as follows:

- Validated transport model including all component physical and chemical properties:
 - Down-the-channel pseudo-two-dimension (2D) model will be refined and validated with data generated in the project.
- Public dissemination of the model and instructions for exercise of the model:
 - Project website to include all data, statistics, observations, model code and detailed instructions.
- Compilation of the data generated in the course of model development and validation:
 - Reduced data used to guide model physics to be published and described on project website.
- Identification of rate-limiting steps and recommendations for improvements to the plate-to-plate fuel cell package:
 - Model validation with baseline and auto-competitive material sets will provide key performance limiting parameters.

FY 2011 Accomplishments

- Generated distributed down-the-channel current, ohmic resistance, temperature and liquid water validation data for a baseline material set.
- Developed new characterization methods to measure transport relationships as a function of saturation.
- Generated characterization data for bulk and interfacial transport in bulk membrane, thin ionomer films, dispersed catalyst layers, gas diffusion layers and gas delivery channels.
- Developed wet model framework.

- Published validation and characterization data to a project website at: www.pemfcdata.org.

Introduction

The transport physics associated with fuel cell operation is widely debated amongst researchers because comprehensive micro/nano-scale process validation is very difficult. Furthermore, fuel cell operation has a strong interdependence between components making it difficult to separate the key relationships required for predictive models with *ex situ* methods. Generally, a validated model that predicts operation based on known design parameters for fuel cell hardware and materials is highly desired by developers. Such a model has been proposed by many research groups for dry (less than 100% relative humidity [RH] exhaust) operation with moderate success, however these modelers unanimously assert that their ability to predict wet operation is limited by two-phase component-level understanding of transport processes. Additionally, as two-phase models continue to be refined; benchmarking progress is difficult due to incomplete validation datasets.

In the current work, our team is developing characterization tools for saturated relationships based on the evolution of a dry 1+1D model for accurate wet prediction [1]. To complement this work we are also developing a comprehensive validation dataset based on a wide proton exchange membrane fuel cell (PEMFC) operating space. As data and modeling reach a final form, these are uploaded to a project website at www.pemfcdata.org. All characterization and validation work is conducted with a common material set.

Approach

This project is organized around baseline and next-generation material sets. These materials define parametric bounds for component and integrated down-the-channel modeling efforts. The baseline material set was chosen based on the commercial state of the art that exists today. The next-generation material set consists of transport impacting parametric changes that are in-line with the DOE 2015 targets for reduced cost while improving durability and performance. For characterization and validation experiments, a standard protocol was also developed to enable the team to conduct experiments with the same boundary conditions.

The first phase of this project was experimentally focused on characterization work that is organized by transport domain, comprising thin film ionomers, bulk membranes, porous electrodes, gas diffusion layers and flow distribution channels. More specifically, the key relationships being investigated are outlined as follows:

- Ionomer Characterization
 - Membrane water uptake, water diffusivity and hydraulic permeability.
 - Oxygen and water transport as a function of ionomer layer thickness.
 - Evidence of nanophase/water morphological changes vs. film thickness.
- Diffusion Layer Characterization
 - Microporous layer thermal conductivity and D/D_{eff} as a function of saturation.
 - Catalyst layer liquid water pressure as a function of saturation, pore size, and hydrophobicity.
 - Substrate thermal conductivity (wet and dry) and D/D_{eff} as a function of saturation.
 - Through-plane saturation and wet region boundary as a function of dT and operating temperature.
- Channel Characterization
 - Carbon fiber paper (CFP) to channel interfacial transport resistance as a function of channel saturation.
 - Channel dP as a function of saturation, temperature, flow, and current density.
 - Manifold dP as a function of saturation, temperature, and flow.

These relationships are required to develop component models that output bulk and interfacial transport resistances to the project 1+1D down-the-channel model. In anticipation of this integrated model, a validation data set is being collected in parallel with small scale hardware specifically designed to include automotive stack constraints [2].

Results

Project Website

The project website was made available to the public at www.pemfcdata.org. This information tool is designed for sharing project data and modeling with the broader fuel cell research community to provide a common validation tool that generates dialog about fundamental transport physics in PEMFCs. A navigational map of the current website is given in Figure 1.

This website contains a 'Home' and 'Project' page that describes the funding, participants, news, approach, deliverables, standard materials and testing protocol. The 'Macro' page contains the down-the-channel validation data for the baseline material set and the next-generation material set will be uploaded in the next phase of the project. The 'Micro' page is continuously being updated with characterization data as it becomes available. The list of model parameters is posted to the 'Parameters' page. This list is currently posted for the dry-based model only, which is available on the 'Modeling' page (the wet model is currently being developed and will be posted in the second phase

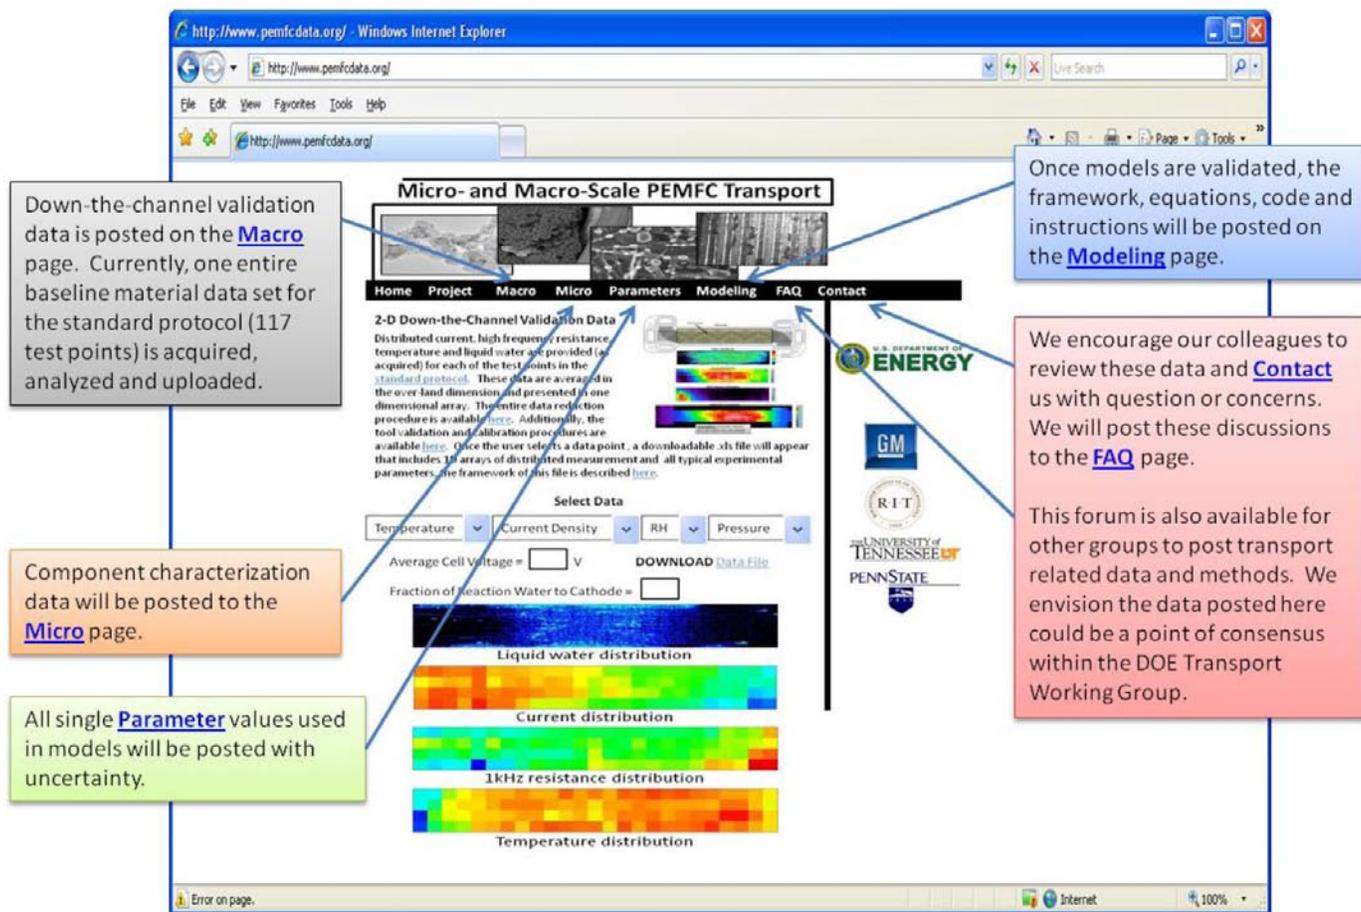

FIGURE 1. Project Website Navigational Map

of the project). Finally, the ‘Contact’ and ‘FAQ’ pages are intended to initiate dialog regarding our data and approach.

Baseline Validation Data

Experimental variability was carefully examined prior to collecting the baseline material set data for the 117 point standard protocol. With regard to the controlled test parameters, temperature control with cartridge heaters was found to have the most significant impact on test variation. RH fluctuations within the cell result from temperature variations as heaters cycle, and this impacts all aspects of transport within the cell. Liquid coolant with flow and temperature control was used to mitigate this experimental variability, which was confirmed with our temperature distribution tool by comparing the temperature distributions with and without coolant. This comparison showed a constant temperature profile is achieved with liquid coolant. Moreover, the temperature distribution is more representative of a commercial fuel cell system with coolant, as the temperature gradient should increase toward the coolant outlet side. For this reason, most 50 cm² validation experiments will utilize liquid coolant during the course of the project.

The validation data set includes distributed liquid water, current, high frequency resistance and temperature measured across the active area. Additionally, anode vs. cathode water balance based on condensed outlet water was collected for each test point. A tool (shown in Figure 1) was developed to navigate this database such that our team and other interested researchers can select a test point from the standard protocol to download the raw and processed data. Currently the validation dataset is fully populated for the baseline material set.

Transport in Thin Ionomer Films

Ellipsometric, microbalance, and fluorescence measurements on thin Nafion[®] films have been performed on model surfaces. These characterization techniques on ionomer films with thicknesses between 30 and 600 nm are designed to probe the transport and swelling properties of the thin ionomer films in the catalyst layers. Ellipsometry and microbalance measurements can give us highly accurate measurements of the water content and swelling of these films as a function of RH. The fluorescence measurements shed light on the dynamics of the film, which governs the

water self-diffusion and transport properties. Fluorescence measurements probe the dynamics in the aqueous domains and we have also used grazing incidence small-angle X-ray scattering to probe their structure. Both the water uptake or hydration number (λ) and self-diffusion of water within the film determines its oxygen and proton transport properties as these species move through the aqueous domains of the material. Select microbalance and fluorescence are presented herein to demonstrate the sensitivities being observed in thin films.

Microbalance results shown in Figure 2a indicate that water content for different film thicknesses was similar for Nafion[®] films on gold thicker than 500 nm [3]. At lower thicknesses, slightly lower water contents were observed, especially at high vapor water activities. The origin of the observed depression in water content is still unclear. Interaction of the ionomer with the Au substrate could constrain the film from swelling, which is essential for water sorption. It is also conceivable that a water impermeable layer (disordering of water channels) at the gas/ionomer interface may contribute to the observation. Fluorescence intensity measurements of 9-([E]-2-carboxy-2-cyanovinyl)julolidine (CCVJ) in thin Nafion[®] films given in Figure 2b show that the fluorescence response is a function of thickness. Higher I/I₀ response indicates stiffening of the film upon water uptake which is not observed for the membrane, but has been reported for other thin films [4]. Since the CCVJ fluorescence signal is controlled by the local viscosity or mobility of the sample, it can be used to measure water diffusion in polymers [5]. The I/I₀ signal will be related to the self-diffusion coefficient of water in the next phase of this work. These measurements indicate different water dynamics in thin and thick films and provide fundamental information on potential differences in proton conductivity and other transport properties as a function of film thickness.

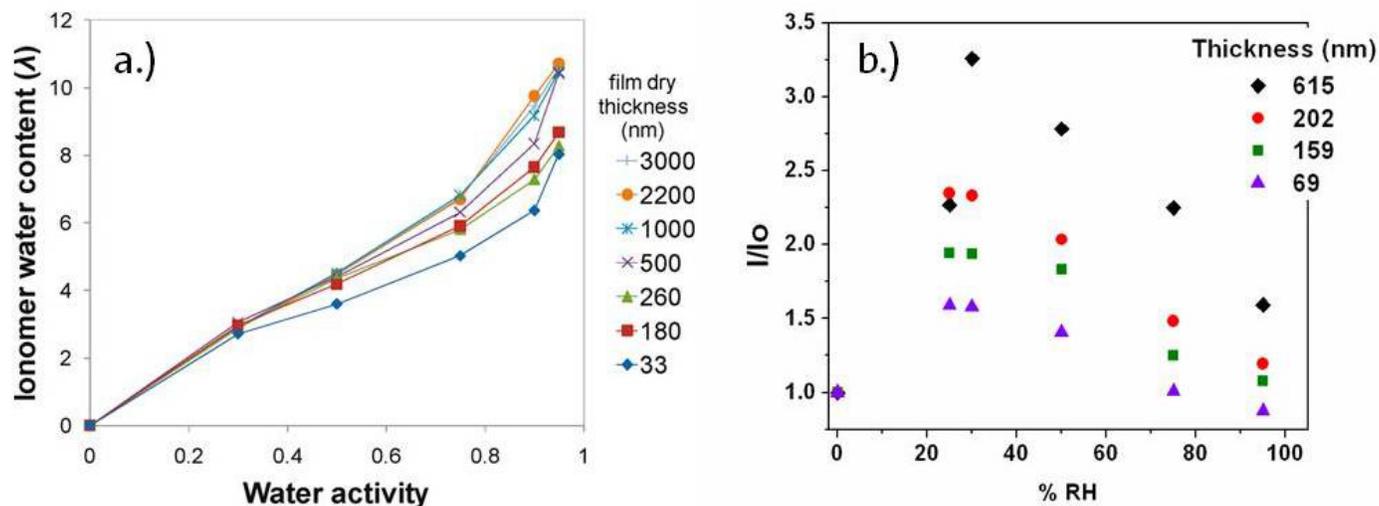

FIGURE 2. Water interaction with varying thicknesses of thin Nafion[®] films as a function of water activity: a) water uptake at 80°C, b) CCVJ fluorescence response at 25°C.

Transport in Diffusion Materials

Several in situ and ex situ measurements are being used to measure transport in the porous components that include the electrode, microporous layer and carbon fiber macroporous substrate. In situ neutron imaging, infrared imaging and acoustic microscopy are being used to map through-plane liquid water distributions within the anode vs. cathode diffusion layers. Ex situ work is focused on thermal conductivity and mass diffusivity as a function of water saturation, and capillary pressure relationships for the baseline diffusion media and catalyst layer are underway. Unique test cells and methodology capable of controlling saturation have been developed to complete this testing.

One characteristic result from the standard protocol has been selected for presentation in this paper and the complete reduced data set has also been made public at the website. Measured with high resolution neutron imaging, Figure 3a shows the effect of anode vs. cathode outlet pressure differentials on water saturation. The operating temperature is 40°C, anode/cathode RH is 95/95% and the current density is 0.8 A/cm². It is evident from the plot how the higher pressure on the cathode side shifts the saturation towards the anode and vice versa. These data provide insight into the complex water balance to be modeled. The corresponding voltages have also been recorded in the plot. Polarization curves obtained with fast scans after each operating condition (Figure 3b) demonstrate the effect of the pressure differential on performance. The false color images in Figure 3c show the regions of water accumulation relative to the land/channel geometry for the specific operating conditions. These data also indicate how sensitive anode gas diffusion layer (GDL) saturation is, and this is not typically considered in two-phase models to this point.

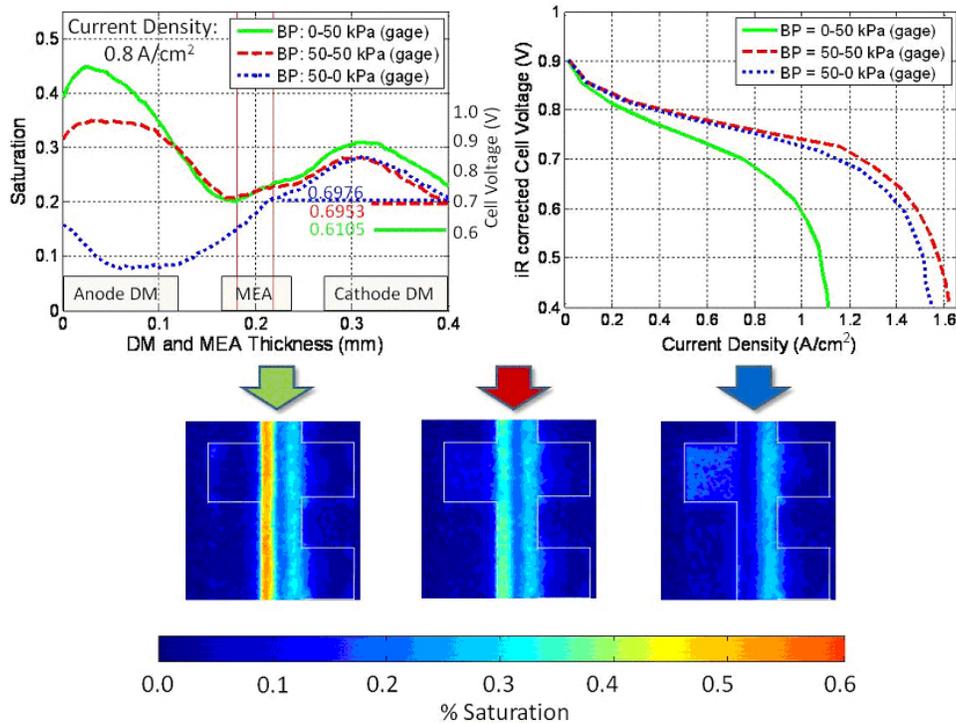

FIGURE 3. Impact of varied outlet pressure: a) GDL water saturation and through-plane, b) polarization curves, c) false color images showing saturation.

Transport in Flow Distributor Channels

Two key components of the down-the-channel model are the relationships between channel water saturation and both CFP to channel interfacial transport resistances, and the channel pressure drop. Therefore, it is critical to establish a well-defined channel water saturation metric. A technique has been developed to quantify the in situ channel water saturation through the combined utilization of high speed videos of the flow field channels during operation and digital image processing [6]. The image processing algorithm automatically detects static and dynamic liquid water, and also characterizes the flow structure of each water object. The water coverage ratio parameter along with channel pressure drop as a function of saturation are providing crucial information pertaining to transport resistance associated with liquid water accumulation in the flow field channels. Sample images showing pre- and post-processed flow field channels and the resulting water detection are shown in Figure 4. In addition to this characterization of water adjacent to the CFP in the active area, experiments are underway to characterize the resistance of liquid water transitioning from the bipolar plate micro-channels in the gas manifolds of a fuel cell stack. Here the combination of low gas shear and contact line pinning has been found to cause water stagnation at the plate edge. This results in additional plate-to-plate flow variations that must be captured in a true two-phase fuel cell model.

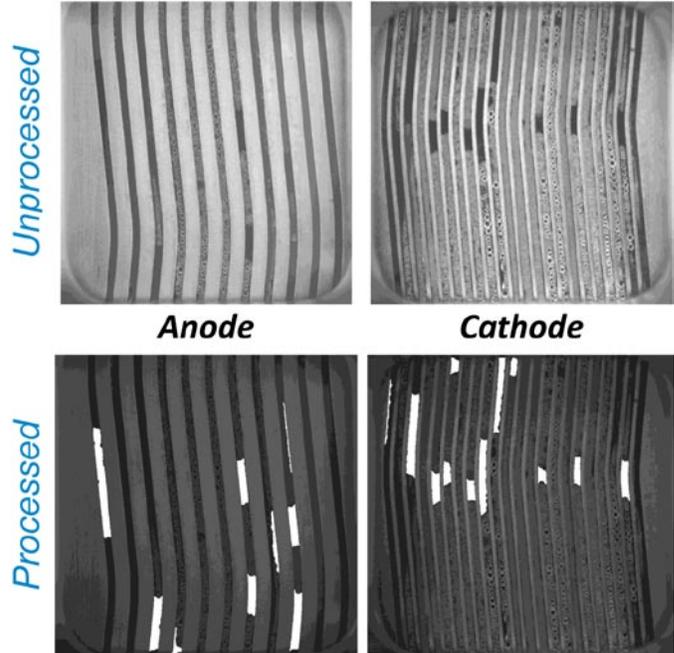

FIGURE 4. Representative unprocessed and processed high speed images of liquid water distribution in both anode and cathode channels. The processed images can provide quantified information of local and overall water coverage ratio.

To optimize the channel design for better water management, the effects of channel surface wettability, cross-sectional geometry and orientation on the two-phase flow in parallel gas channels were investigated. It was found that hydrophilic channels are advantageous over uncoated or slightly hydrophobic channels in terms of uniform water and gas flow distribution and promoting film flow. Stamped metal geometry channels favor film flow when compared to a rectangular geometry. Vertical channel orientation is advantageous over horizontal orientation because it is less prone to slug flow, and facilitates more uniform liquid water distribution and stable operation.

Conclusions and Future Directions

A well organized characterization, modeling and validation framework was developed early in this project. The first phase of execution was largely focused on experimental development with key accomplishments outlined as follows:

- Project is standardized by materials and operating space:
 - Baseline and auto-competitive material sets chosen based on parametric variations that consider degradation and cost vs. performance trade-offs.
- Key relationships required for a wet 1+1D model and characterization methods are defined:
 - Subject matter experts are developing and executing characterization methods to generate physical understanding of fundamental processes.
 - Component models describing processes are being generated and will be used to output bulk and interfacial transport resistances.
 - Modeling framework for 1+1D model is defined.
- Down-the-channel baseline material validation data set complete:
 - Additional repeat experiments being executed to define uncertainty.
- Database on the website for dissemination of data and modeling:
 - Visit www.pemfcdata.org (development will continue throughout the project).

The next phase of this project is focused on refining the component and down-the-channel models in parallel while repeating characterization and validation work for the next-generation material set. This work will support the key deliverable for next year: a validated 1+1D model capable of predicting performance and water balance under saturated conditions with baseline material parameters.

Contract Number: DE-EE0000473

Subcontractor:
Ballard Power Systems, Burnaby, British Columbia, Canada

Project Start Date: June 1, 2009
Project End Date: November 15, 2011

Technical Barriers

This project addresses the following technical barriers from the Fuel Cells section of the Fuel Cell Technologies Program Multi-Year Research, Development and Demonstration Plan:

- (A) Durability (with respect to start-up, freezing and low relative humidity operation)
- (B) Cost (with respect to stack and balance of plant [BOP] trade-off)
- (C) Performance (with respect to voltage degradation, low relative humidity and sub-zero performance)

Technical Targets

- Stack/system concept that is suitable for sub-zero operation down to -30°C.
- Durability for an air-cooled fuel cell stack $\geq 5,000$ hours operating under material handling conditions including start-stop cycles; a 2x improvement over baseline testing.
- GenDrive™ product cost reduction of 25% or greater using air-cooled stack design over baseline liquid-cooled GenDrive™ product.

FY 2011 Accomplishments

- Conducted screening tests on 27 membrane electrode assembly (MEA) technologies, stack durability tests on five MEA technologies and system compatible testing on three MEA technologies.
- Built a system test bench to test all system interactions, especially the fuel cell and battery, before final packaged design solution was complete. Prior testing was performed on three stack module test benches where the system interactions are managed within an analytical model.
- Completed testing of advanced system operating strategies for the FCvelocity™ 1020ACS air-cooled stack with over 6,000 hours of operation using two advanced operating strategies. These operating strategies focus on reducing cathode catalyst dissolution and corrosion and chemical and mechanical stress on the membrane. System operating strategies provide a 2x extension in durability compared to previous tests.
- Built a prototype system and performed system level high and low ambient temperature testing. Test results demonstrate an air-cooled stack system can operate continuously at both high and low ambient temperature conditions however system improvements are required to optimize performance to ensure long life.

Fiscal Year (FY) 2011 Objectives

- Advance the state of the art in technology for air-cooled proton exchange membrane (PEM) fuel cell stacks and related GenDrive™ material handling application fuel cell systems.
- Demonstrate FCvelocity™ 1020ACS stack durability of 5,000 hours (2.5x nominal durability) through enhanced system operational strategies or utilization of advanced fuel cell stack materials.
- Determine a stack/system concept that is suitable for sub-zero operation down to -30°C.
- Determine a stack/system concept that achieves a total cost that is competitive with incumbent materials handling fuel cell technology solutions.
- Develop, evaluate and trade-off the stack and system to meet materials handling requirements for freeze and cost.
- Develop an understanding around integrating air-cooled stack technology into a dynamic materials handling system.
- Perform life-cycle cost analyses for freeze tolerance strategies.

- The project Go/No-Go review was held with the DOE in December 2010. The project cost metric was met and the DOE approved the recommendation to continue the project and advance to Phase 2.

Introduction

Plug Power's objective is to advance the state-of-the-art fork-lift technology by using air-cooled fuel cell stacks and improving related GenDrive™ material handling systems to improve function and reduce cost. This will be accomplished through a collaborative work plan to reduce overall system cost by simplifying the system BOP through the use of an air-cooled stack as well as improve freeze tolerance and mitigate freeze-thaw failure modes through innovative fuel cell system design.

The fuel cell system, derived from Plug Power's commercially available GenDrive™ platforms, is providing battery replacement for equipment in the material handling industry. The fuel cell stacks are Ballard's commercially available FCvelocity™ 9SSL (9SSL) liquid-cooled PEM fuel cell stack and FCvelocity™ 1020ACS air-cooled PEM fuel cell stack. Stack modifications to the FCvelocity™ 1020ACS will be explored through this project. Plug Power will lead design-build-test and design-of-experiment efforts for GenDrive™ systems with support from Ballard Power Systems for the fuel cell stack and stack integration.

Approach

In this project the fuel cell stack, system and fuel cell stack operation will be designed together in order to trade off stack durability and freeze function with overall stack-system cost. Both stack and system level mitigation of freeze failure modes will be explored. The project will develop an understanding of market needs, system requirements, stack-system limitations, historical data, models and small-scale testing to define stack/system operating strategies that achieve required freeze function and durability.

Multiple design, build, test cycles will be employed to increase learning through iteration. Analytical models for durability and freeze will be developed and verified on stacks and system modules. Accelerated testing will be used where possible to reduce testing time. Stacks and systems will be operated under material handling freezer conditions, failure analysis will be performed to understand the root cause of failures, stacks and systems will be designed to mitigate the failure modes, then built and tested. Trade-off analysis will be used to determine the design solutions that are built and tested.

Results

The FCvelocity™ 1020ACS (ACS) stack must first demonstrate performance and durability targets to

be considered a viable GenDrive™ product solution. Specifically, the ACS must demonstrate 5,000 hours running a representative load profile including start-stop cycles. The self-humidifying ACS stack is an "open cathode" design where cooling and reactants are supplied by a single fan. This offers system simplicity by eliminating the liquid cooling system, humidifiers, air compressor and on-board water management; providing a significant cost reduction compared to a liquid-cooled, closed cathode stack. As a result the MEA operates very dry, all start-ups are air-air start-ups and, under freeze conditions, the cooling power of the air stream is high making low current density operation difficult. All of these conditions increase the stack degradation and make function under freezing conditions a challenge.

Based on stack/MEA failure modes, two advanced system level operating strategies were developed to mitigate the known failure mechanisms:

- Air-air starts degrade the catalyst and cause voltage degradation.
- Time at open-circuit voltage (OCV) degrades the membrane and causes transfer leaks.
- High currents and stack temperatures stress the membrane.
- Mixed potentials (at start-up and shutdown) degrade the catalyst.

Figure 1 shows stack module bench test results of two system tests for average cell voltage, cumulative number of air-air starts and transfer leak rate versus operating hours; one operating strategy focused on reducing membrane degradation (time at high cell potential) while the other focused on reducing voltage degradation (number of air-air starts). The system strategy to reduce the number of air-air starts demonstrates a lower degradation rate compared to the system strategy that reduces the time at OCV. In the approach to reduce the number of air-air starts, hydrogen is kept on the anode for long periods; the result is more time spent at high cell potentials (or OCV) which has the side effect of increasing the membrane stress. To reduce membrane stress, time at high potentials can be minimized with a possible side effect of increasing the number of air-air starts. A trade-off is required between the two cases because in most cases reducing the number of starts and reducing the time at OCV are linked. The strategy to reduce OCV inherently has more air-air starts and as a result has a higher voltage degradation rate. Less time spent at OCV can increase the time for the MEA to develop a leak because there is less time spent in a state that is damaging to the membrane. Figure 1 also illustrates that although the reduced OCV strategy has the highest voltage degradation rate, it went over 6,000 hours without any indication of a transfer leak. By comparison the reduced starts operating strategy shows signs that a transfer leak was initiated after 5,000 hours due to the time spent at high cell potentials. In this system the end of life criteria is more related to voltage

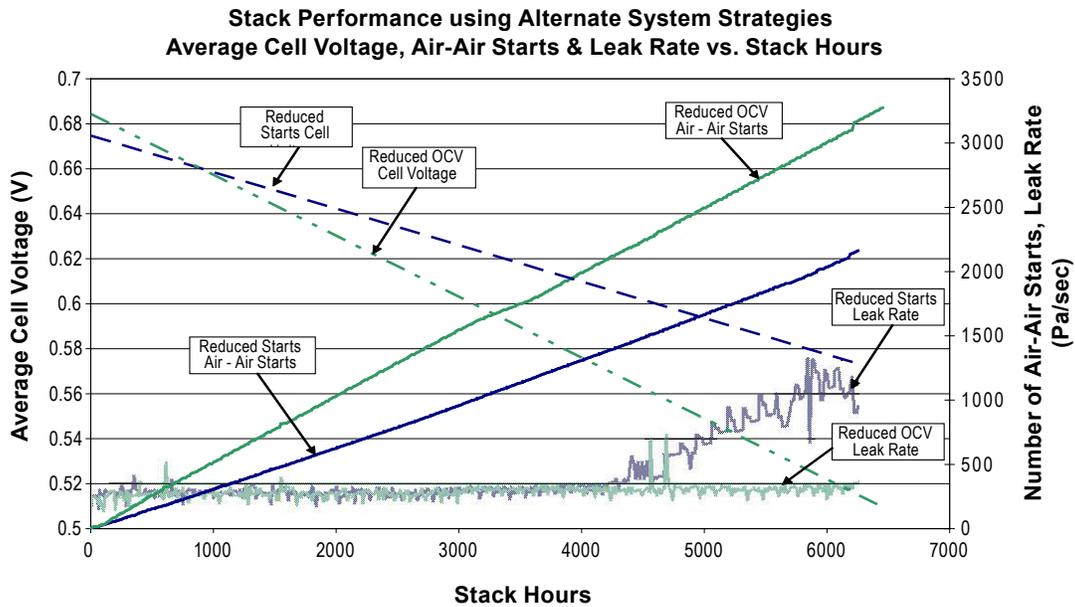

FIGURE 1. Stack Life Test Results

so managing low levels of hydrogen leaks will be accepted in order to extend life.

A prototype system using an air-cooled stack was built and instrumented for purposes of evaluating an air-cooled stack operating at low ambient temperature conditions. All development needed to build a prototype system was undertaken so that a proper system level evaluation could be made. This included activities such as battery hybrid integration, high pressure hydrogen storage integration and controls software development.

Multiple system features for low ambient temperature operation were designed into the prototype system in order to evaluate how each influences performance. A high ambient temperature test was performed first to evaluate any negative effects of system design features intended to allow low ambient temperature operation. The initial high ambient temperature testing indicated excessive pressure drop across the inlet air filter selected for the prototype design. Initially, the stack temperature exceeded the set point even with the fan at maximum speed. Removal of the filter during the test demonstrated the optimal stack temperature could be achieved with the fan operating below 60% capacity. An inlet air filter with lower pressure drop will need to be designed for the next level of tests.

The ambient temperature was then reduced to -30°C while operating a low load profile, reference Figure 2. Although stack temperature is near optimum under freezer conditions, the asymmetry of the air recirculation path produces a non-optimal gradient in stack inlet air temperature (T1, T2 and T3 are different inlet locations). Also discovered during the -30°C testing was ice formation in the air recirculation stream. As the warm exhaust air entered the cold air inlet chamber some of the moisture

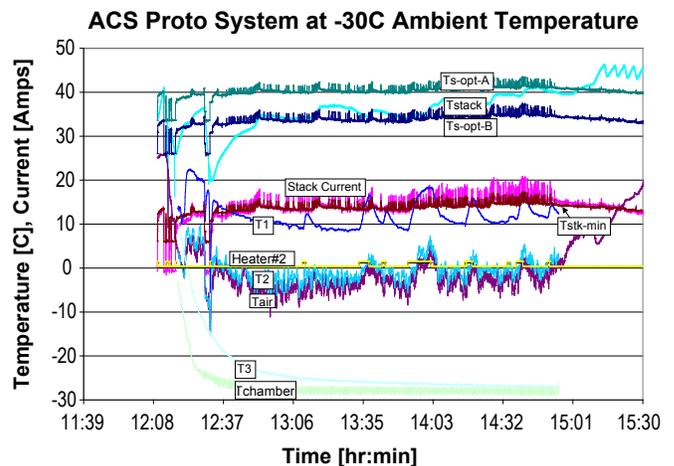

FIGURE 2. Low Ambient Temperature System Test Results

would condense then freeze. Uniform air temperatures across the stack inlet and control of the condensing moisture are critical for sustained -30°C operation. These issues are slated to be addressed during the design mitigation phase of the project.

The project Go/No-Go is based on a cost metric of a product utilizing the air-cooled stack technology. Inherent in developing the product cost is that the air-cooled fuel cell stack solution must meet minimum performance and durability requirements to even be considered for a commercial product. The metric states that a GenDrive™ product cost reduction must be 25% or greater using air-cooled stack design over baseline liquid-cooled GenDrive™ product. A comparison of initial product cost and lifecycle cost is shown in Figure 3. Several product comparisons

are made using the 2009 liquid-cooled (9SSL Technology) GenDrive™ product as the baseline. Cost reductions for the 9SSL in 2010 are primarily from supply chain initiatives. An additional 9SSL cost reduction is projected based on continued supply chain initiatives plus concept system architecture.

The first air-cooled stack comparison is made with Ballard Power System’s ACS second generation MEA with 5,000 hour durability. The product cost was estimated using both a top down and bottom up approach; both estimates resulted in very similar (<4% difference) cost estimates. The top down approach started with the existing liquid-cooled product and subtracted and added component differences. The bottom up approach assumed a clean sheet design and cost estimates were applied to each subsystem based on the system process and instrumentation diagram and the actual prototype system. The second air-cooled stack comparison was made with Ballard Power Systems Advanced ACS MEA.

As can be seen, reductions in initial product cost utilizing liquid-cooled technology are starting to level out whereas product cost projections utilizing the air-cooled stack technology indicate a possible step change for the order picker product. All costs are shown normalized to the baseline. A Go/No-Go review was held with the DOE and the project was approved to advance to the next phase of design mitigation to issues uncovered during freeze testing.

One of the major issues uncovered during freeze testing was a non-uniform stack inlet air temperature gradient. Warm exhaust air is re-circulated to the stack inlet and mixed with the cold inlet air to reduce the effects of freezing air on the cathode. Computation fluid dynamics was used extensively to optimize the stack inlet air velocity and temperature gradients in the freezer (-30°C ambient

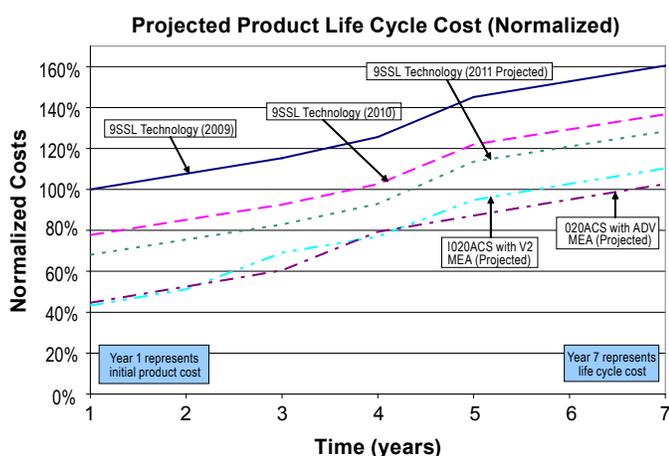

FIGURE 3. Life Cycle Cost Analysis

temperature) environment. The initial air recirculation duct work had decent velocity gradients but large temperature gradients at the stack inlet. The air recirculation duct work was then evaluated and re-designed to reduce the air temperature gradients. Figure 4 shows the temperature profile after refinements were made to the air recirculation. The velocity profile is now very uniform; however there is still an area of the stack inlet that has a lower temperature than the rest of the stack. Some additional refinement is still required to reduce the stack inlet air temperature gradient while operating in the freezer.

Conclusions and Future Directions

- Ballard’s FCvelocity™ 1020ACS can meet the durability and cost requirements of the order picker GenDrive™ with modified system operating strategies designed to reduce the number of air-air starts.
- With Ballard’s FCvelocity™ 1020ACS, the order picker GenDrive™ cost is lower than the liquid-cooled solution even with system strategies to handle freeze condition.
- Complete the design mitigation strategies for issues discovered during the low and high ambient temperature testing.
- Build prototype systems with mitigation strategies.
- Test prototype systems with mitigation strategies at low and high ambient temperatures.

- Pennsylvania State University, State College, PA
- University of Tennessee at Knoxville, Knoxville, TN

Project Start Date: September 1, 2009

Project End Date: August 31, 2012

- (C) Performance
- (E) System Thermal and Water Management

Technical Targets

This project is primarily focused on reducing stack cost and improving efficiency by modeling and optimizing transport properties of the membrane electrode assembly (MEA). Stack cost is reduced through a combination of increased power density and decreased noble metal content. The performance target of 7.5 W/mg-Pt @ 500 mV was selected, based on cost modeling results, as the performance required to achieve the 2015 DOE cost target of \$15/kW_e. Efficiency (electric potential at rated current) of the stack technology will be optimized with the ultimate goal of approaching the 2015 DOE efficiency targets:

- Stack efficiency @ rated power: 55%
- Stack efficiency @ 25% of rated: 65%

FY 2011 Accomplishments

- A new gradient preserving single-cell fixture capable of high power density operation was delivered to University of Tennessee, Knoxville (UTK)/Penn State University (PSU), and Johnson Matthey Fuel Cells (JM).
- Single-cell testing was conducted on two flowfield architectures, and the results suggest that the performance advantage of open flowfield is the result of improved oxygen diffusion to the cathode reaction sites.
- A two-dimension (2D)+1 mathematical model capable of predicting high current density operation in different architectures was developed and refined, and the accuracy of the model was partially validated with experimental testing.
- MEAs with low Pt loading electrodes, thin membranes, and low equivalent weight (EW) ionomer in the electrodes were developed and optimized for performance at ultra-high current densities.
- The Go/No-Go milestone was satisfied by demonstrating >1 W/cm² @ 0.2 mg-Pt/cm² on a full-format stack.

Fiscal Year (FY) 2011 Objectives

- Develop and publish a predictive transport model that enables efficiency maximization at conditions that meet DOE cost targets.
- Demonstrate stable and repeatable high performance on a full-format fuel cell stack, namely 7.5 W/mg-Pt.
- Optimize the efficiency (electric potential at rated current) of a stack technology that meets DOE cost targets.

Technical Barriers

This project addresses the following technical barriers from the Fuel Cells section of the Fuel Cell Technologies Program Multi-Year Research, Development and Demonstration Plan:

- (B) Cost

Introduction

Hydrogen fuel cells are recognized as one of the most viable solutions for mobility in the 21st century; however, there are technical challenges that must be addressed before the technology can become available for mass production. One of the most demanding aspects is the costs of present-

day fuel cells which are prohibitively high for the majority of envisioned markets. The fuel cell community recognizes two major drivers to an effective cost reduction: (1) decreasing the noble metals content, and (2) increasing the power density in order to reduce the number of cells needed to achieve a specified power level. Nuvera's technology exhibits great promise for increasing power density on account of its proven ability to operate stably at high current densities ($>1.5 \text{ A/cm}^2$). However doing so compromises efficiency, increases the heat rejection duty, and is thus more demanding on the cooling system. These competing aspects are being assessed in order to identify the proper trade offs, and ensure the modeling and experimental activities of the AURORA Program respect system-level constraints for automotive applications. This project will develop a predictive transport model to identify and help us reduce losses and increase efficiency for high current density operation.

Approach

Nuvera structured the activities in the scope of the project to orbit around a focal point consisting of the fuel cell predictive model. Cost and system analyses were performed in order to define the boundaries of the design space that the model should represent. This analytical work will inform the experimental tests on a new single cell fixture to illuminate the physics and the parameters composing the backbone of the fuel cell model. The predictions generated by the model drive both the process of optimization of the fuel cell operating conditions and the material development. The combined results of these two activities are verified on single cell fixtures as well as on full active area hardware, and the experimental data obtained is used to validate and calibrate the model through multiple iterations.

Results

In FY 2011 Nuvera delivered a new gradient preserving single-cell open flowfield (SCOF) cell to partners UTK/PSU and JM. A new single-cell test station was also received and commissioned to facilitate SCOF testing at Nuvera. A number of test station issues were resolved with hardware upgrades, and the test station is now fully verified, and SCOF testing has begun.

UTK/PSU tested both a conventional land/channel cell and the Nuvera SCOF cell in order to compare the two architectures. The results highlight a significant advantage of the SCOF cell to operate at ultra-high current densities without suffering from diminishing return of power density. As shown in Figures 1 and 2, the conventional land/channel cell exhibits significantly lower performance with air than with heliox while the Nuvera SCOF cell exhibits almost the same performance with both oxidants. The SCOF cell operating with air also exhibited similar performance to the conventional land/channel cell operating with heliox. These results suggest that the performance advantage of the SCOF is the result of improved oxygen diffusion to the cathode reaction sites.

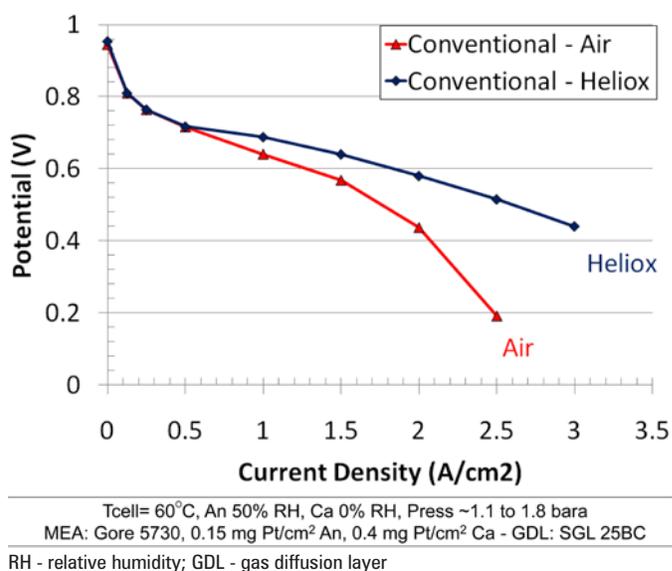

FIGURE 1. Air vs. Heliox Performance Comparison of Conventional Land/Channel Architecture

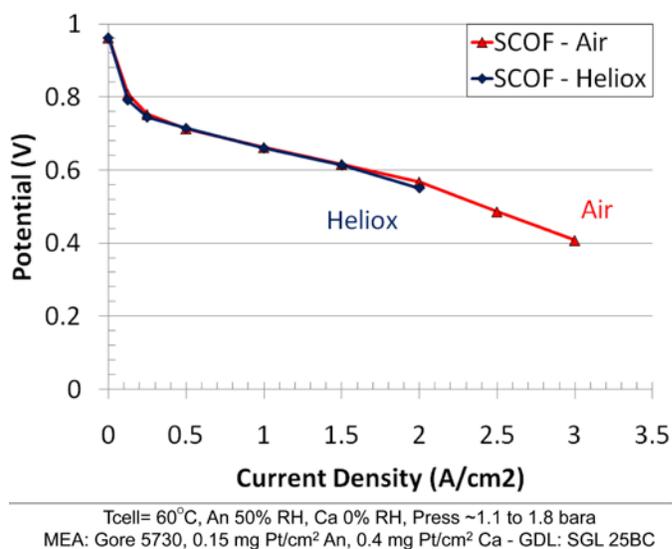

FIGURE 2. Air vs. Heliox Performance Comparison of SCOF Cell With Open Architecture

UTK/PSU also developed and refined a 2D+1 mathematical model capable of predicting high current density operation for different flowfield architectures. The physics and electrochemistry of a previously implemented 2D model was used to create a new 2D+1 "AURORA model" capable of simulating both the conventional land/channel and Nuvera open flowfield architectures. Significant additional physics were added to the model formulation in order to more accurately predict water, gas, and heat transport, and an advanced agglomerate electrode model from Lawrence Berkeley National Laboratory (LBNL) was integrated into the model in order to provide

a more accurate account for cathode kinetic loss. The accuracy of this model has been partially validated with simultaneous in situ experimental testing in terms of performance, high frequency resistance (HFR) and net water drag coefficient. The predictions from the 2D+1 model are compared with experimental results in Figure 3 in terms of performance and HFR with close agreement. Consistent with experimental results, the computational model predicts that the HFR increases with current density, which signifies the onset of the possible membrane dry-out in the ultra-high current density regime. The experimental and modeling investigation found that for the open flow field architecture, gas phase mass transport is not the limiting factor even in the ultra-high current regime.

JM developed low Pt loading MEAs optimized for performance at ultra-high current densities. JM produced and tested a number of MEA design iterations in order to develop an MEA with low Pt loading electrodes, a thin low resistivity membrane, and low EW ionomer in the electrodes. First, a low loading (0.2 mg/cm^2) electrode design was optimized with a thin membrane to achieve a performance improvement of $50 \text{ mV @ } 2 \text{ A/cm}^2$ over the baseline which had higher Pt loadings (0.5 mg/cm^2) and a thicker membrane. This optimized MEA was produced and delivered to Nuvera for testing. The performance of the MEA was then improved even more by using a low EW ionomer (between 750 and 850) in the electrode. Initial versions of the MEA with low EW ionomer exhibited performance lower than expected as a result of significant electrode flooding. The electrode was then optimized for water management, and the final version was able to achieve a performance improvement of $40 \text{ mV @ } 2 \text{ A/cm}^2$ in the JM single cell. This new MEA design was also produced and delivered to Nuvera for testing. Development work has started for anode electrodes with very low Pt loading (0.02 mg/cm^2). Initial results show promise at low current

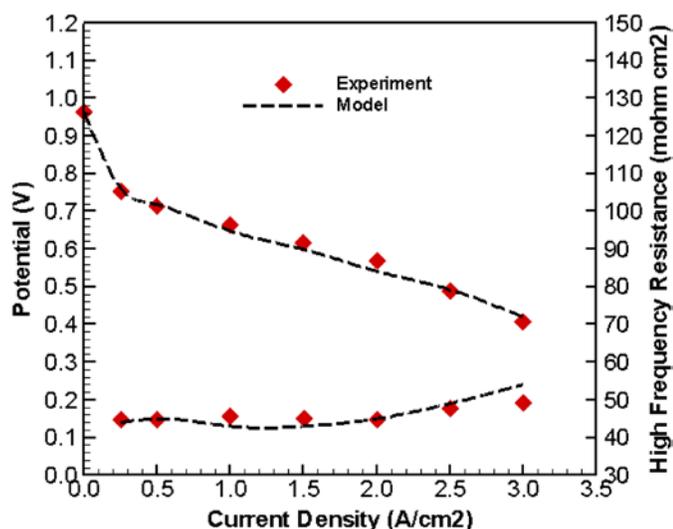

FIGURE 3. Comparison of Voltage and HFR between Experiment and Model

densities, however water management has been an issue at high current densities thus far.

Nuvera tested various developmental MEAs from JM on full format automotive stacks. Figure 4 shows performance of two optimized MEA designs, MEA 23 (blue) has a thin membrane with high Pt loadings (0.5 mg/cm^2), and MEA 25 (red) has the same thin membrane with low Pt loadings (0.2 mg/cm^2). As expected, the low Pt loading MEA exhibits lower performance in the low current density Tafel region ($30 \text{ mV lower @ } 0.2 \text{ A/cm}^2$) due to lower electrochemical surface area; however, the ohmic losses of this MEA are lower and the performance approaches that of the high loading MEA at high current density (2 A/cm^2). The high performance demonstrated by the low loading MEA of $0.548 \text{ V @ } 2 \text{ A/cm}^2$ exceeded the $1 \text{ W @ } 0.2 \text{ mg-Pt/cm}^2$ target and satisfied the Go/No-Go milestone for the project.

Conclusions and Future Directions

Nuvera has demonstrated high performance (5.57 W/mg-Pt), satisfying the Go/No-Go milestone, and Nuvera will continue evaluating JM development materials with the goal of demonstrating stable and repeatable high power performance of 7.5 W/mg-Pt on a full format fuel cell stack.

JM has achieved significant Pt reduction and performance improvements at high current density and will continue executing the materials development plan investigating reduced loading anode electrodes, graded Pt cathode electrodes, and novel MEA architectures.

UTK/PSU has developed, refined, and partially validated a predictive 2D+1 mathematical model using feedback from simultaneous in situ experimental testing. UTK/PSU will continue tuning and validating the model, in

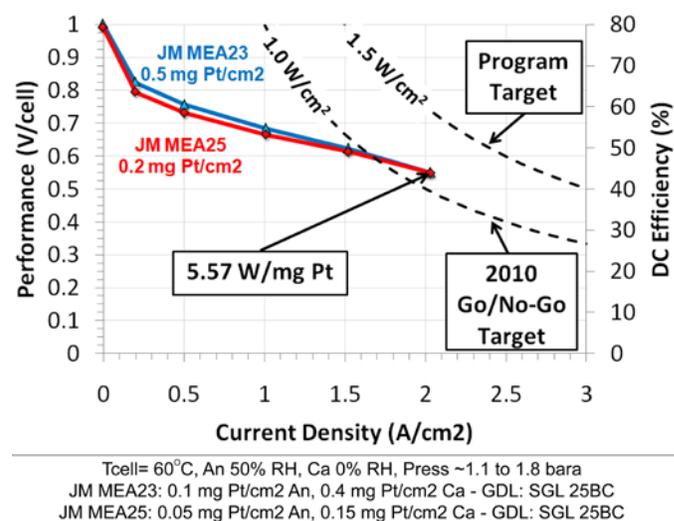

FIGURE 4. Performance Curves of Standard and Low Loading JM MEAs with Thin Membranes

terms of performance, HFR, and net water drag coefficient, with the goal of publishing a fully validated predictive model at the end of the project.

Project Start Date: September 21, 2009

Project End Date: September 30, 2013

Technical Targets

This project is conducting fundamental investigations into fuel cell operation at low and subzero temperatures. The knowledge gained will enable various metrics to be met or exceeded. These include those related to durability, performance, and cost. Specifically,

- Durability
 - 5,000 hr (automotive) and 40,000 hr (stationary).
 - Thermal cycling ability with liquid water.
- Performance
 - Unassisted start from -40°C.
 - Cold start to 50% power in 30 seconds and with 5 MJ or less energy.
 - Efficiency of 65% and 55% for 25% and 100% rated power, respectively.
 - Stack power density of 2 kW/kg.
 - Platinum group metal (PGM) loading of 0.2 g/kW.
- Cost: \$15/kW_e

Fiscal Year (FY) 2011 Objectives

- Fundamentally understand transport phenomena and water and thermal management at low and subzero temperatures.
- Examine water (liquid and ice) management with nano-structured thin-film (NSTF) catalyst layers.
- Enable operational and material optimization strategies to be developed to overcome observed performance bottlenecks.
- Characterize and measure critical transport properties for operation with liquid water.
- Elucidate the associated degradation mechanisms due to subzero operation and enable mitigation strategies to be developed.

Technical Barriers

This project addresses the following technical barriers from the Fuel Cells section of the Fuel Cell Technologies Program Multi-Year Research, Development and Demonstration Plan:

- (C) Performance
- (A) Durability
- (D) Water Transport within the Stack
- (E) System Thermal and Water Management
- (G) Start-Up and Shut-Down Time and Energy/Transient Operation

FY 2011 Accomplishments

- Completed cold-start model and demonstrated that proton limitations may exist during isothermal cold starts as ice lenses build up near the membrane interface.
- Determined impact of membrane thickness, catalyst-layer thickness, and ionomer-to-carbon ratio on isothermal cold-start behavior.
- Developed capabilities and experimental protocols for measuring capillary-pressure-saturation relationships for both gas diffusion layers (GDLs) and microporous layers (MPLs). Demonstrated that this relationship is critical and can be used to explain water transport throughout the material. Also designed a test fixture for measuring water distributions using X-ray tomography.
- Developed rate expression from theory and fit to experimental data showing kinetic freezing phenomena inside GDLs.
- Measured water properties in a traditional catalyst layer including ionomer water uptake and capillary-pressure saturation relationship.

Introduction

Polymer electrolyte fuel cells experience a range of different operating conditions. As part of that range, they are expected to be able to survive and start at low and subzero temperatures. Under these conditions, there is

a large amount of liquid and perhaps frozen water due to the low vapor pressure of water. Thus, water and thermal management become critical to understanding and eventually optimizing operation at these conditions. Similarly, durability aspects due to freezing and low temperatures are somewhat unknown and need further study in order to identify mechanisms and mitigation strategies. In addition, it is known that thin-film catalyst layers such as the NSTF developed by 3M have issues with large amounts of liquid water due to their thinness. These layers provide routes towards meeting the DOE cost targets due to their high catalytic activities. This project directly focuses on the above aspects with the goal that improved understanding will allow for the DOE targets to be met with regard to cold start, survivability, performance, and cost.

Approach

The overall approach is to use a synergistic combination of cell, stack, and component diagnostic studies with advanced mathematical modeling at various locations (national laboratories, industry, and academia). Ex situ diagnostics will be used to quantify transport properties and to delineate phenomena that are used in the modeling. The multiscale modeling will account for stack position through boundary conditions that are fed to a pseudo three-dimensional or one plus two-dimensional cell model. This model will be used during shutdown to predict the water profile during the subsequent cold start. The model will be validated by comparison of measured in situ cell performance in both stacks and single cells. Durability will be probed by doing cycling and other stress tests as well as taking failed cells from the in situ testing and duplicating their failure ex situ. To understand controlling phenomena and the impact of various layers, a systematic investigation at the component scale will be accomplished. After initial baseline cell assemblies have been tested and explored, various components will be switched to understand the impact of each one on both performance and durability.

Results

When fuel cells operate at low and subzero temperatures, liquid water and water management become more important. Thus, there is a need to study properties of the porous fuel cell layers in the presence of liquid water. As noted last year, the capillary pressure–saturation relationship is critical in understanding the two-phase properties of fuel cell layers. This year, we used this technique to examine the properties of a catalyst layer. For this study, an extra thick (about 30 microns) catalyst layer was made using the tradition ink painting process. This layer was then tested using our capillary pressure apparatus [1], and the results are shown in Figure 1a. As can be seen, the layer is about 60% hydrophilic, which is much different than the results of a GDL, which shows hydrophobic behavior on imbibition and a mixed wettability response. Similarly, we tested the water uptake of these catalyst layers using dynamic vapor sorption

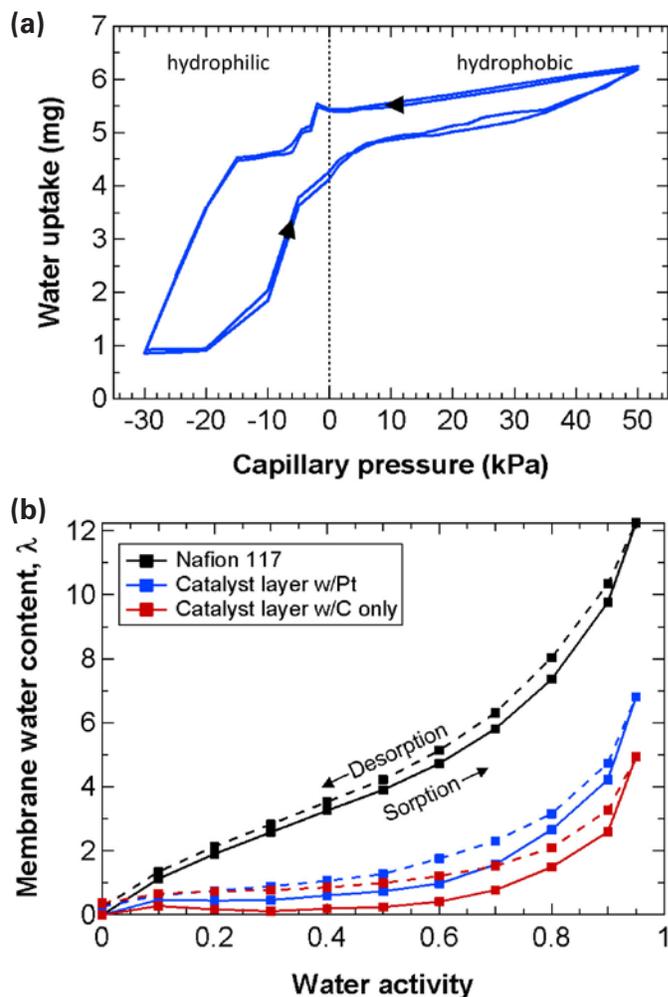

FIGURE 1. (a) Capillary pressure–saturation relationship for a traditional Pt/C catalyst layer. (b) Membrane water content for a Pt/C and C only catalyst layer as a function of humidity (bulk Nafion® is shown as a reference).

apparatus (SMS Instruments). As Figure 1b demonstrates, the water uptake of the ionomer in the catalyst layer is less than that of a bulk ionomer, thereby suggesting a depression of its transport properties as well. Interestingly, samples with Pt/C and not just C show increased water uptake which may be due to the fact that the sulfonic acid sites bind to the Pt (in agreement with results from Oak Ridge National Laboratory), which opens up the membrane morphology to accept more water.

Other diagnostics are aimed at determining what happens when water freezes in the various fuel cell layers. Using nucleation theory and dynamic scanning calorimetry, we were able to develop a rate expression for water freezing inside of a GDL. This expression was used to predict the onset of freezing under different subcoolings as shown in Figure 2. It is interesting to note that ice will not form in GDLs until substantial subcooling has occurred, even over long periods of time. However, that is not to say that freezing will not occur in other components, especially flow fields.

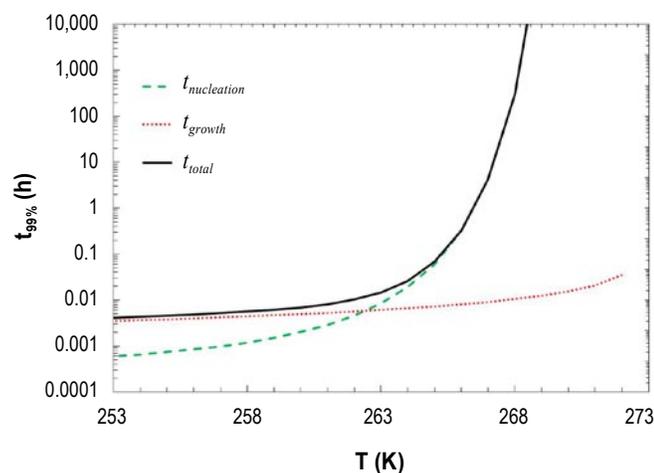

FIGURE 2. Prediction of time to freeze in a GDL as a function of subcooling using experimentally fit and theoretically derived rate expression.

To understand ice formation as a function of MEA properties, isothermal cold-start experiments were undergone. The main variables altered were the catalyst-layer thickness, membrane thickness, and ionomer to carbon ratio. Figure 3a shows the results of changing the membrane thickness, where thicker membranes allow for more water production as long as the temperature is high enough. The reason is that at lower temperatures, there is not a sufficient diffusion flux for water to get into the membrane and saturate it. Figure 3b shows the impact of catalyst-layer thickness, where thinner catalyst layers do not seem to have enough storage capacity to allow for more water generation before failure. This could be critical for NSTF and is something being investigated for next year. Finally, Figure 3c shows the impact of ionomer to carbon ratio. At low values, there is not enough ionomer to provide good proton conductivity and thus the water production before failure is low. However, at high ionomer-to-carbon-ratio contents, the ionomer begins to fill in the pore space of the catalyst layer, thereby limiting oxygen transport and storage capacity of the produced water.

Mathematical modeling was used to understand both isothermal and nonisothermal cold start. The nonisothermal cases demonstrate that starting either at lower voltages or with drier membranes lead to better performance. For isothermal cold start, the simulations demonstrate that the entire pore capacity of the catalyst layer may not be used during the start, especially at high current densities. The reason for this is that an ice front forms and propagates from the membrane interface towards the interface with the GDL as shown in Figure 4. The ice-front propagation is driven by the nonuniform reaction-rate distribution that occurs at high current densities, which is why it is not seen in the case of lower current densities which have a more uniform reaction-rate distribution. The end result of the ice front is that at higher current densities, the cell becomes ohmically limited

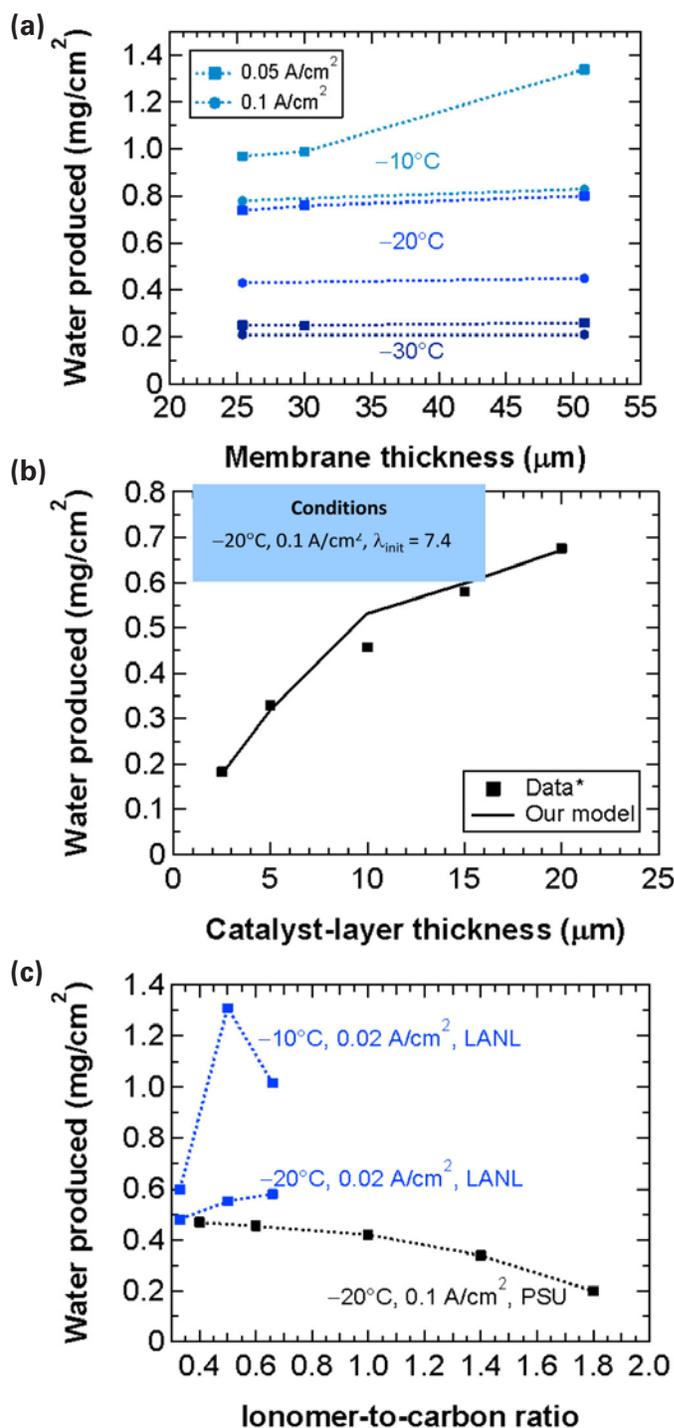

FIGURE 3. Isothermal cold-start data showing water produced before zero volts as a function of (a) membrane thickness, (b) catalyst-layer thickness, and (c) ionomer-to-carbon ratio.

since the protons cannot reach the reaction site as it goes further from the membrane. Thus, the zero cell voltage is not due to a true limiting current and zero oxygen concentration, but due to proton conduction limitations. Understanding these interplays and phenomena will allow for optimum

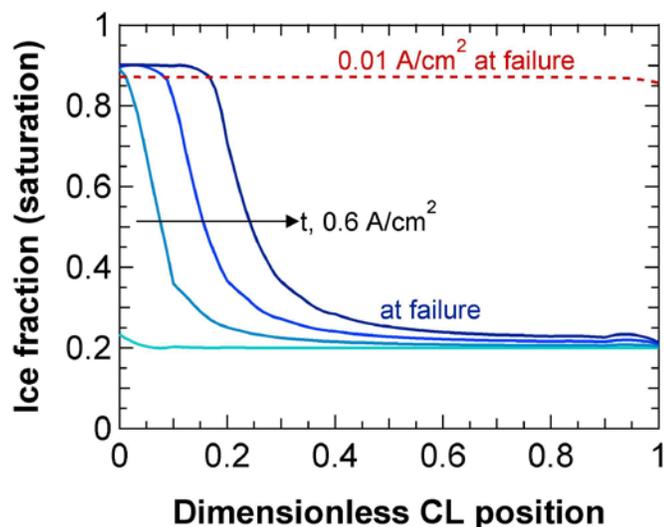

FIGURE 4. Isothermal cold-start simulation results showing ice-fraction profile as a function of time for two current densities.

starting conditions and material properties to be determined such that DOE targets for cold start can be met.

Conclusions and Future Directions

The project focus this year was on exploring liquid and ice formation in traditional catalyst layers and GDLs. The experiments demonstrated the hydrophilicity of the catalyst layer although some hydrophobic character remains; reduced water uptake in catalyst-layer ionomer; the need to subcool GDLs to induce freezing; and that thicker catalyst layers with around 0.4 ionomer-to-carbon ratio provide the best chance to cold start due to their increased water capacity and sufficient ionic conductivity. In addition, the cold-start model was finished, with results helping to explain experimental observations with both isothermal and nonisothermal cold starts including the fact that ohmic and not oxygen mass-transfer limitations can become limiting during cold start at higher current densities. In terms of future work, this can be summarized as:

- Cell Performance
 - Testing of non-baseline assemblies.
 - Isothermal and adiabatic starts including cycling studies for tracking durability.
 - Provide model-validation data.
- Component Characterization
 - Catalyst layers
 - More data on water-related properties.
 - Examine ice generation and form using infrared thermography and X-ray tomography.
 - Diffusion media
 - Capillary pressure – saturation relationships.

Impact of flowrate, temperature, injection sites (MPL analogs), materials.

- Measure effective gas-diffusion coefficient as a function of saturation.
- Modeling of Cold Start
 - Examine interplay between water storage and movement for transient and startup.
 - Develop three-dimensional to two-dimensional downscaling correlations.
 - Model the low-anode-pressure and alternative-GDL results that 3M has obtained.
- Stack studies for temperature distribution and performance characterization.
- Understand and increase the operating window with thin-film catalyst layers.

Project Start Date: July 20, 2009

Project End Date: September 30, 2011

- (A) Durability
- (B) Cost
- (C) Performance

Technical Targets

This project aims to improve the catalytic activity and durability of PtRu for the MOR via optimized catalyst-support interactions. Insights gained from these studies will be applied toward the development and demonstration of DMFC anode catalyst systems that meet or exceed the following DOE 2010 Consumer Electronics targets:

- Cost: \$3/W
- Specific power: 100 W/kg
- Power density: 100 W/L
- Lifetime: 5,000 hours

FY 2011 Accomplishments

- Established the effect of nitrogen dosage and nitrogen functionalities on catalyst durability using the model HOPG system.
- Determined that the dopant type (N_2^- , N_2/H_2 - CF_4 , O_2^- and I_2 -doped HOPG) affects MOR activity and durability.
- Developed a tool and process for effective ion implantation and sputter deposition processes applicable to high surface area carbon materials.
- Developed and optimized PtRu sputter deposition methods from a single composition PtRu alloy target to produce highly dispersed PtRu nanoparticles of a desired catalyst composition and metal loading on high surface area carbon supports.
- Demonstrated that in-house magnetron sputter deposited PtRu/N-doped Vulcan carbon catalysts are more durable than both the undoped in-house catalysts and commercial PtRu/C catalysts.
- Demonstrated that in-house sputter deposited PtRu/C catalyst outperforms a commercial catalyst in a DMFC.

Fiscal Year (FY) 2011 Objectives

Our primary objective is to improve the catalytic activity and durability of PtRu for the methanol oxidation reaction (MOR) via optimized catalyst-support interactions.

- Determine the effect of ion implantation of highly oriented pyrolytic graphite (HOPG) on the catalyst activity and stability of PtRu catalyst nanoparticles deposited by vapor or solution phase processes.
- Determine the effect of doping level and type of dopants (e.g., n or p) on the catalytic activity and durability of the PtRu/HOPG model catalyst system.
- Apply the understanding established from the dopant-engineering approach of the model HOPG planar materials to high surface area carbon supports. The goal is to improve catalyst utilization, activity, and durability for membrane electrode assemblies (MEAs).

Technical Barriers

This project addresses the following technical barriers from the consumer electronics section of the Fuel Cell Technologies Program Multi-Year Research, Development and Demonstration Plan (section 3.4.4):

Introduction

High material cost and insufficient catalytic activity and durability are key barriers to the commercial deployment of DMFCs—the most advanced fuel cell technology for consumer electronics application. DMFCs are attractive for portable commercial and military applications because they offer extremely high theoretical energy density.

To accelerate the commercialization of DMFCs for consumer electronics applications, next generation materials based on leap-frog technology are needed. In DMFCs, the MOR on the anode limits the performance and durability. Breakthroughs in DMFC anode catalysis with respect to performance, cost and durability will help enable and accelerate the commercialization of DMFCs.

Approach

This project focuses on improving the catalytic performance and long-term durability of the anode catalyst for the MOR. Our approach is to modify and optimize catalyst-support interactions in order to substantially increase activity, selectivity, and durability of PtRu catalytic systems. The team systematically investigated the effects of ion-implantation on HOPG, as a model support analogue as demonstrated by a series of recent publications [1-6] on PtRu catalysts. These well-defined systems allow us to assess dopant effects and provide a test-bed for exploring new dopant/catalyst combinations. These undoped and doped, via ion implantation, carbon substrates are decorated with PtRu using both aqueous solution and physical vapor methods. The catalysts are characterized with various techniques such as microscopy, Raman spectroscopy, X-ray diffraction (XRD), X-ray photoelectron spectroscopy (XPS)

and electrochemistry to determine the catalyst particle size, dispersion, composition, structure, degree of alloying, MOR activity and electrochemical durability. The catalyst synthesis process and materials are down-selected based on performance and transferred to high surface area carbon studies for further study. The highest performing materials are used in DMFC testing.

Results

We demonstrated that nitrogen implantation on HOPG has a beneficial effect of improved methanol oxidation catalytic activity and durability. XRD results showed no difference in the PtRu composition, structure, or crystallite size for PtRu on N-doped HOPG, Ar-HOPG or undoped HOPG. However, the methanol oxidation activity was higher for PtRu on N-HOPG. Nitrogen doping resulted in an inherent chemical effect and an improved stability as was predicted by theory [2-3].

We also established the role of nitrogen in the durability of PtRu/HOPG catalyst via microscopy and XPS analysis. Figure 1 shows PtRu nanoparticles on N-doped HOPG samples before and after 300 cycles between 0 and 1.1 V vs. Ag/AgCl, at 250 mV/s in 1 M H₂SO₄, for different levels of N-doping. Before cycling, the transmission electron microscope (TEM) images show that PtRu coverage and

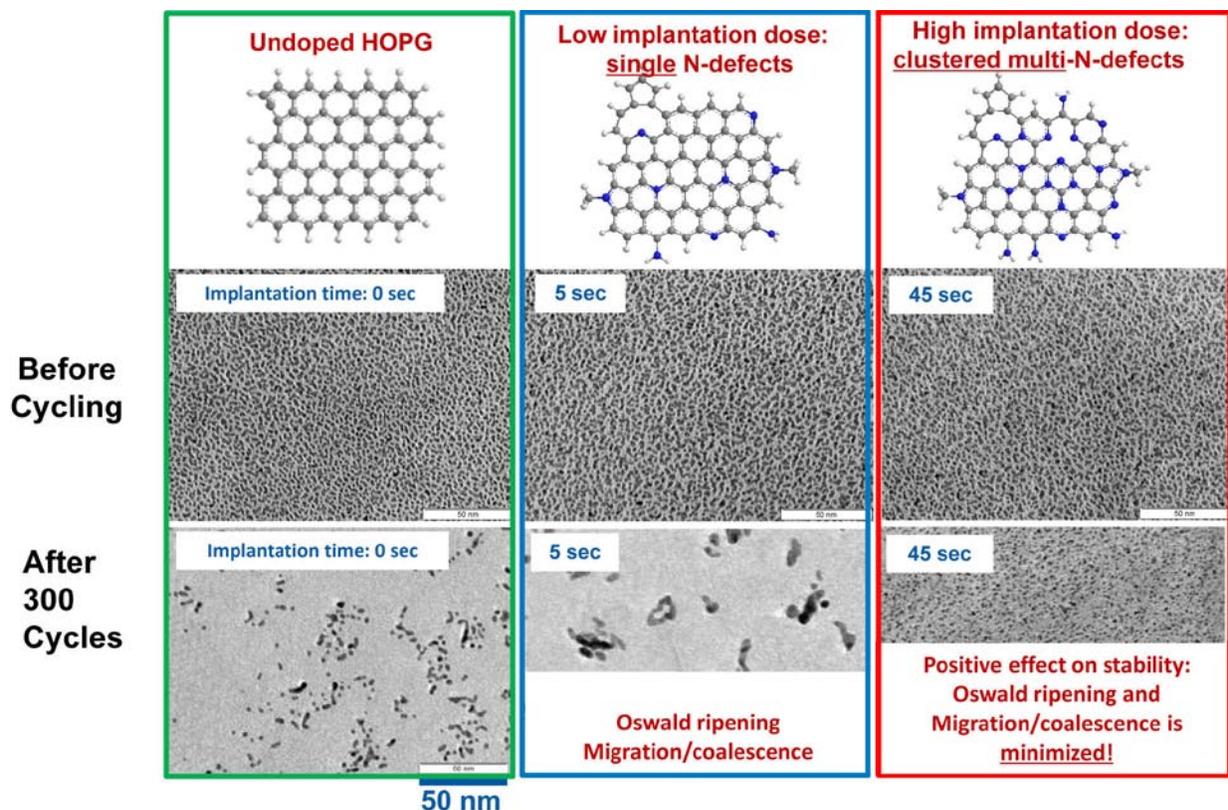

FIGURE 1. TEM images showing the effect of N-dosage on catalyst durability following potential cycling. High N-dosage results in clustered multi-N-defects, which have a positive effect on the stability of PtRu nanoparticles on N-doped HOPG.

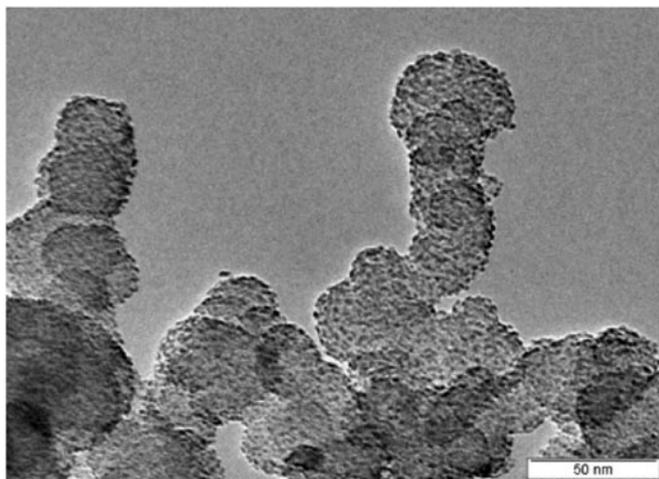

FIGURE 2. Representative TEM sputter-deposited PtRu/Vulcan carbon materials.

composition are independent of the amount of nitrogen present. After cycling to 1.1 V, low implantation dose (5-15 s) resulted in poor stability while high implantation dose (45, 100s) seemed to have greatly increased particle stability. The results indicate that a high amount of N is needed to form clustered multi-N-defects, which appears to minimize coalescence/migration of the PtRu catalyst. Density functional theory (DFT) was used to infer the effect of specific N functionalities on the stability of PtRu. DFT calculations show that N-defects such as pyrrolic and pyridinic N enhances the stability of Pt in PtRu and that pyrrolic N improves the stability of PtRu by stabilizing both Pt and Ru. Hence, a balance between pyrrolic and pyridinic N is needed to stabilize PtRu catalyst.

We established an entirely vapor-phase process for PtRu catalyst material development. By controlling specific, yet interdependent, sputter deposition parameters, we were able to generate high performing and highly dispersed PtRu nanoparticles (Figure 2) of a desired composition, particle size and electroactive surface area on Vulcan carbon support. Table 1 compares the half-cell MOR specific and mass activity of in-house catalysts and a commercial catalyst of a similar metal loading (30 wt%) and PtRu composition (1:1 atomic%). Our in-house sputtered PtRu/C catalysts consistently showed 20%–30% improvement in MOR activity as compared to commercial catalyst of comparable composition. Furthermore, the NREL in-house PtRu

on N-doped carbon catalyst proved more durable than the undoped catalyst and commercial catalyst. Further optimization is needed to improve the MOR activity for the in-house N-doped catalysts.

Table 1 compares the electrochemical surface area (ECA), the MOR specific and mass activity, and durability of two in-house and one commercial 30 wt% PtRu/C catalysts. JM5000 is a commercial catalyst purchased from Johnson Matthey. PtRu/N-C is a catalyst that has about 5% N-incorporated in the Vulcan carbon via implantation, followed by sputter deposition of PtRu. The ECA was obtained from CO stripping voltammetry. The MOR activity was measured in a half-cell set up in 1 mol/L methanol + 1 mol/L H₂SO₄. The durability test was done by cycling between 0.23 and 0.80 V vs. reference hydrogen electrode at 20 mV/s in 1 M H₂SO₄. All measurements were carried out at room temperature.

TABLE 1. Half-Cell Catalyst Performance and Durability Comparison

Catalyst	ECA (m ² /g)	Specific Activity @ 0.4 V (μA/cm ² _{metal})	Mass Activity @ 0.4 V (A/mg _{metal}) X 10 ³	% of ECA after 100x Durability cycles	% of ECA after 5,000x Durability cycles
30 wt% PtRu/C (sputter)	73	33	24	51	10
28 wt% PtRu/N-C (sputter not optimized)	55	30	17	60	40
30 wt% PtRu/C JM5000	69	29	20	48	17

The non-solution process was scaled up to generate a sufficient amount of the best performing in-house catalyst for DMFC testing. Table 2 shows that the in-house sputter 30 wt% PtRu/C outperforms the DMFC commercial catalyst JM5000. MEA preparation method needs to be optimized to improve the DMFC performance further.

Table 2 shows that in-house sputtered PtRu/C catalyst outperforms the commercial JM5000 catalyst of the same catalyst loading (1 mg/cm²). DMFC testing was carried out at 50°C using a 5 cm² MEA, 1 mol/L methanol and humidified air. Anode polarization was carried out using 1 mol/L methanol on the anode and hydrogen on the cathode. ECA was measured using CO stripping voltammetry.

TABLE 2. Catalyst DMFC Performance Comparison

Catalyst	PtRu ECA (m ² /g)	DMFC Current Density @ 0.4 V			Anode Polarization @ 0.4 V	
		(mA/cm ²) Geometric Surface Area	(μA/cm ² _{metal})	(mA/mg)	(μA/cm ² _{metal})	(mA/mg)
JM500	55	25	45	25	48	26
Sputtered PtRu/C	41	30	73	30	83	34

Conclusions and Future Direction

- We demonstrated that nitrogen implantation has an inherent beneficial effect on MOR activity and durability and that nitrogen dosage and functionalities play a role on these effects.
- We established an entirely non-solution, scalable process that produced highly dispersed PtRu/C catalyst that outperformed commercial catalysts in both MOR specific and mass activity.
- We demonstrated that PtRu on N-doped Vulcan carbon catalysts are more durable than PtRu on undoped carbon and commercial catalysts.
- We screened several different chemical dopants and determined that dopant level of interaction with carbon matrix affects MOR activity and durability.
- We will continue to optimize catalyst utilization through sputter-implantation parameter control.
- We will evaluate the DMFC performance and durability of PtRu/implanted carbon catalyst materials.
- We will establish catalyst degradation mechanisms, e.g., extent of ruthenium dissolution and catalyst coarsening.
- We will perform soft X-ray and hard X-ray scattering studies in situ during electrochemical analysis to determine the sites for PtRu attachment and study the degradation of PtRu during cycling (at the SLAC National Accelerator Laboratory).

Contract Number: DE-EE0000474

Subcontractors:

- QuantumSphere Inc. (QSI), Santa Ana, CA
- Illinois Institute of Technology (IIT), Chicago, IL

Project Start Date: July 1, 2010

Project End Date: June 30, 2013

Objectives

- Develop ultra-thin membranes having extremely low methanol crossover, high conductivity, durability, and low cost.
- Develop cathode catalysts that can operate with considerably reduced platinum loading and improved methanol tolerance.
- Produce a membrane electrode assembly (MEA) combining these two innovations that has a performance of at least 150 mW/cm² at 0.4 V and a cost of less than \$0.80/W for the membrane and cathode catalyst.

Technical Barriers

This project addresses the following technical barriers from the Fuel Cells section of the Fuel Cell Technologies Program Multi-Year Research, Development and Demonstration Plan for portable power devices:

- Durability
- Cost
- Performance

Technical Targets

This project is conducting focused research on next generation membrane and cathode catalyst materials for direct methanol fuel cells. Insights gained from these studies will be applied toward the design of an MEA for portable power applications that meet the DOE 2010 targets:

- Performance: specific power (100 W/kg), power density (100 W/l), and energy density (1,000 Wh/L)
- Cost: \$3/W
- Lifetime: 5,000 hours

In translating DOE-published targets, we have defined the following goals for the membrane, cathode catalyst, and MEA performance based on our modeling efforts (Table 1).

TABLE 1. Progress towards Meeting the Project Technical Targets for Portable Power Applications

Characteristic ¹	Units	Industry Benchmark	Project Target	Status
Methanol Permeability	cm ² /s	1-3x10 ⁻⁶	5x10 ⁻⁸	1.5x10 ⁻⁷
Areal Resistance, 70°C	Ωcm ²	0.120 (7 mil PFSA ³)	0.080	0.080
Cathode Catalyst Specific Power (rotating disk electrode, RDE) ²	mW/mg Platinum Group Metal (PGM)	25	>50	>100
MEA Cathode Catalyst Loading	mg/cm ² PGM	2.5	2	In progress
MEA Current-Voltage Cell Performance (0.4 V)	mW/cm ²	90	150	120 ⁴
MEA Lifetime	hours	>3,000	5,000	In progress

¹ Targets based on a methanol concentration of 1M

² Conditions at 0.45 V vs. standard hydrogen electrode and 70°C

³ Perfluorinated sulfonic acid

⁴ Measured with commercial gas diffusion electrode (GDE) with 1.5 mg/cm² Pt on the cathode and 4.5 mg/cm² Pt and Ru on the anode. This is intended to be a reference for MEA development work.

Fiscal Year (FY) 2011 Accomplishments

- Identified 15 high potential membrane candidates with the required areal resistance and a methanol permeation coefficient $\leq 3 \times 10^{-7}$ cm²/s. One candidate has a permeation coefficient of 1.5x10⁻⁷ cm²/s, slightly above the milestone target methanol permeation of 1x10⁻⁷ cm²/s.
- Successfully prepared composite membranes with a sulfonated silica additive with no visual indications of large-scale phase separation.

- Demonstrated a power of 120 mW/cm² from an MEA with an Arkema membrane and a commercial GDE.
- Successfully synthesized unsupported palladium and palladium-based nanocatalysts having a surface in excess of 90 m²/g (3-10 nm), both as admixtures and alloys.
- Initiated scale up of Pd catalyst production with an output of 1.2 kg/month at 60% recycling efficiency.
- Achieved a mass activity of 133 mW/mg_{PGM} at 0.45 V for Mn-promoted Pt/C + Pd, which fulfills the target for specific power. This includes an additional 20% reduction in PGM content. Corresponding cost of power is \$0.71/W, a 57% catalyst cost savings compared to commercial Pt/C.

Introduction

There is a tremendous need for small, efficient portable power sources. The explosive growth of the lithium-ion batteries market is fueled by the ever-growing demand for portable power used in consumer electronics. For the direct methanol fuel cell industry to emerge as an alternative to batteries, very difficult technical hurdles have to be overcome in terms of drastically reduced methanol cross-over in the membrane and improved anode and cathode catalyst efficiencies.

Approach

Arkema and IIT are developing a new generation of membranes with very low methanol cross-over and high conductivity. The membranes are formed from blends of poly(vinylidene fluoride) (PVDF) with a variety of highly sulfonated polyelectrolytes, technology that was developed in DE-FC36-04GO14051 and DE-FC36-07GO17008. A number of variables can be easily adjusted in the blending process to tailor the membrane properties, such as conductivity and methanol permeation. The key to obtaining the desired properties resides in control of composition, architecture, and morphology of the membrane components. These are controlled on a practical level through polyelectrolyte chemistry, processing, and use of inorganic materials, which are being systematically investigated and correlated with properties.

QSI is developing a new series of cathode catalysts with improved mass activity obtained by suppressing methanol oxidation. The QSI catalyst has demonstrated higher specific activity for oxygen reduction in the presence of methanol compared to commercially used Pt/C. The scope of work in the first year included development of the synthesis and electrochemical characterization of nanoscale Pd-based catalysts, methods to increase catalyst production yield, and basic MEA testing in anticipation of extensive MEA development and testing for the rest of the project.

Results

Membrane Development

Over 100 membrane compositions were fabricated at Arkema with varying polyelectrolyte compositions, PVDF grades, ratios of sulfonated polyelectrolyte to PVDF, and crosslinking agents. Testing for the compositions focused on ex situ conductivity and methanol permeation. Other testing (crystallinity measurements, microscopy, and mechanical testing) was also carried out on a small number of candidates to understand structure-property relationships and morphology. In-cell testing was also done on about 1/3 of the candidates to validate the ex situ property data.

Data from a majority of the samples is shown in Figure 1, along with PFSA and M43 references. The M43 membrane was developed for H₂ fuel cells and is used as a baseline for this project. All of the variables affected performance, but the polyelectrolyte chemistry had the most influence on membrane permselectivity through changes in polarity, equivalent weight, and molecular weight. The polyelectrolyte:PVDF ratio and PVDF grade, which alter equivalent weight and percent crystallinity respectively, also had a significant impact on membrane conductivity and permeation. Fifteen high potential candidates from the group have the required areal resistance and a methanol permeation coefficient $\leq 3 \times 10^{-7}$ cm²/s. The most promising of these candidates has a permeation of 1.5×10^{-7} cm²/s, slightly above the year one milestone target of 1×10^{-7} cm²/s. Efforts are now focused at refining these high potential candidates to meet the milestone requirements.

The MEA performance of the most promising high potential candidate (Candidate A) and M43 in 3M and 10M

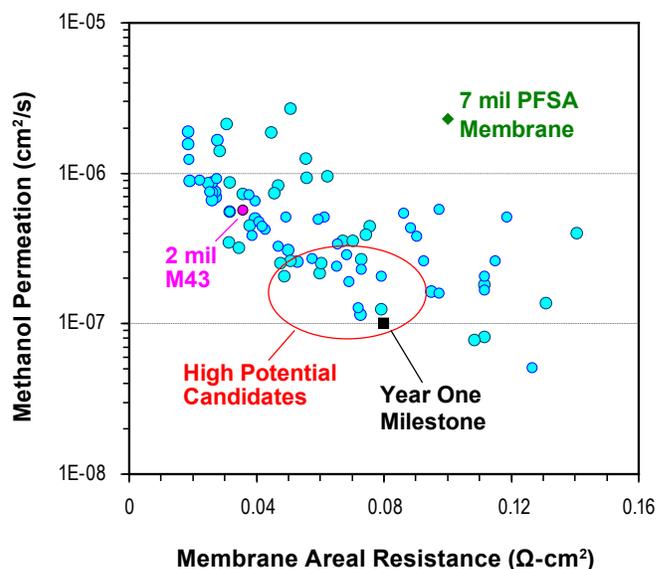

FIGURE 1. Conductivity versus Permeation for the Membrane Compositions Screened at Arkema

methanol is shown in Figure 2. Both materials outperform the PFSA reference at both methanol concentrations. Compared to M43, Candidate A shows slightly higher performance with 10M, and exhibits superior durability due to its mechanical properties. Both Arkema membranes have also demonstrated 120 mW/cm² at 0.4 V with 1M methanol using a commercial GDE from Johnson Matthey, which will be used as a baseline in the next stage of the project where QSI's catalyst and Arkema's membrane are incorporated into an MEA.

IIT has been developing novel sulfonated silica materials for use as conductors in the formulation of composite membranes. Addition of inorganic additives to membranes has been shown to lower methanol permeability, but this is usually combined with a reduction in conductivity [1]. This deficiency may be addressed by functionalizing the silica with sulfonic acid groups.

Mesoporous sulfonated silica particles are made by hydrolyzing tetraethyl orthosilicate with HCl and reacting it with (3-mercaptopropyl) trimethoxysilane. The materials were sulfonated over a range of 30-67% (ion exchange capacity = 1.4-2.1 mmol/g). All of them display high conductivity: 100 mS/cm at 60°C and 100% relative humidity.

Thirty percent sulfonated silica was incorporated into an Arkema formulation and cast into composite membranes. The membranes were transparent with no visual indication of particle aggregation. Data from the composites is shown in Table 2. Permeability and conductivity are lowered as the silica is added. Selectivity is more complex, initially decreasing compared to the reference at the lowest silica loading and then increasing with higher silica contents. The composite properties may be improved by using silica with higher sulfonation and this work is in progress.

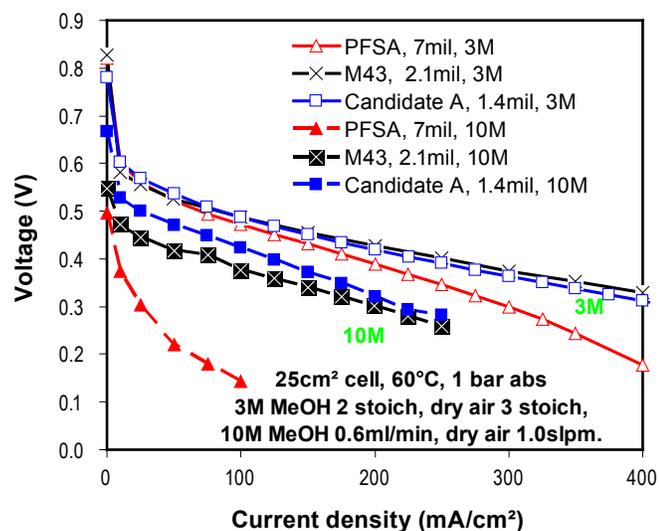

FIGURE 2. Performance of Two Arkema Membranes and a PFSA Benchmark in 3M and 10M Methanol

TABLE 2. Conductivity and Permeation Data for a Membrane Composites Series made with Sulfonated Silica

Membrane + Silica with 30% Sulfonation	Conductivity @ 70°C, mS/cm	Permeability @ Room Temperature, $\times 10^{-7}$ cm ² /s	Conductivity/Perm Selectivity
Arkema membrane	125 ± 7	6.7 ± 0.2	19
With 15 wt% silica	75 ± 4	5.7 ± 0.4	13
With 20 wt% silica	49 ± 1	3.4 ± 0.1	14
With 25 wt% silica	58 ± 9	3.2 ± 0.2	18

Catalyst Development

QSI successfully fabricated Pd and Pd-M (M= Ni, Co, Mn, Fe, Cr, Ag, Au, Se) nanocatalysts with high surface area (>90 m²/g). Catalyst particle sizes are in 3-10 nm range, as illustrated in Figure 3. The oxygen reduction reactivity of Pd-M + Pt/C catalysts (i.e. a mixture) was evaluated using RDE with and without methanol in the electrolyte. The Pd + Pt/C blended catalyst showed doubled mass activity (>100 mW/mg PGM) compared to Pt/C alone in the presence of 0.1M methanol. The resulting PGM costs per watt of various cathode catalysts (assuming cost of \$54.00/g for QSI nano-Pd and \$128.00/g for 60% Pt/C) are shown in Figure 4. Up to 57% cost savings (M = Mn) is realized when a Pd-M co-catalyst is used with Pt/C.

Conclusions and Future Directions

- Identified 15 high potential membrane candidates with the required areal resistance and a permeation coefficient $\leq 3 \times 10^{-7}$ cm²/s.
- Composite membranes with a sulfonated silica additive were successfully prepared. Higher sulfonation

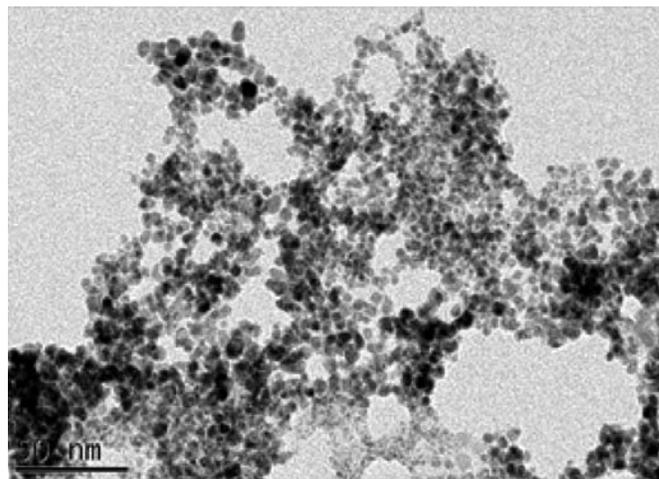

FIGURE 3. Transmission Electron Microscope Image of Pd-Mn Nanocatalysts (The scalebar represents 50 nm.)

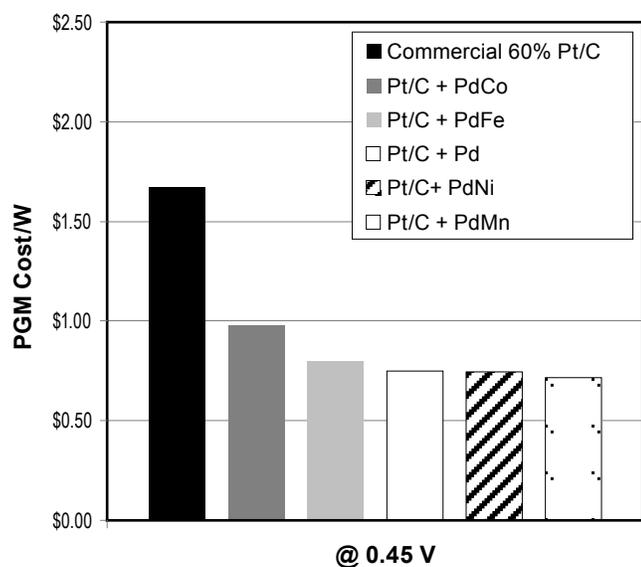

FIGURE 4. Cost of Power at 0.45 V for Cathode Catalyst in the Presence of 0.1M Methanol to Simulate Crossover

levels and better dispersion of the inorganic particles are needed to improve conductivity and decrease permeation, which will be pursued in the future.

- A catalyst containing a mixture of Pt/C + Pd-Mn achieved a mass activity of 133 mW/mg_{PGM} at 0.45 V, which fulfills the target for specific power.

- Down-select membrane and catalyst candidates that meet the year one milestone, refine their properties, and produce target compositions on a pilot-scale for MEA development.
- Initiate MEA development for 50% reduction in PGM content at the cathode to meet the goal of ≤ 2 mg/cm² total PGM loading with the target cell performance.

Contract Number: DE-EE0000475

Subcontractors:

- University of Florida, Gainesville, FL
- Northeastern University, Boston, MA
- Johnson Matthey Fuel Cells, Swindon, UK

Project Start Date: January 1, 2010
Project End Date: June 30, 2012

Fiscal Year (FY) 2011 Objectives

The primary objective of this project is to optimize the functionality and internal water recovery features of the UNF passive water recovery membrane electrode assembly (MEA) to facilitate overall system simplicity, thereby increasing power and energy density and lowering the cost at the system level to address DOE's fuel cell target goals for consumer electronics applications.

- Optimize the UNF MEA design:
 - Improve durability and reliability
 - Increase power and energy density
 - Lower cost
- Develop commercial production capabilities:
 - Scale up the process to commercial batch operation level:
 - Improve performance and lower reproducibility
 - Lower cost
- Increase catalyst stability and lower loading:

- Increase the anode catalyst stability
- Lower MEA cost

Technical Barriers

This project addresses the following technical barriers for consumer based electronic applications of less than 50 W from the Fuel Cells section of the Fuel Cell Technologies Program Multi-Year Research, Development and Demonstration Plan:

- (A) Durability
- (B) Cost
- (C) Performance

Technical Targets

A comparison of the UNF DMFC power supply versus the DOE technical targets for portable fuel cell power supplies is shown in Table 1.

FY 2011 Accomplishments

- Optimized open cathode MEA fabrication processes to provide excellent MEA-to-MEA reproducibility in stack testing.
- Developed MEAs with low on-state degradation $<50 \mu\text{V/h}$ under a range of operating conditions and obtained over 4,000 hours of operation for an eight cell short stack.
- Improved the off-state durability of the MEAs by optimizing the cathode electrode and barrier layer formulation and processing conditions.
- Incorporated system operating conditions to improve MEA off-state durability.
- Scaled up barrier layer coating process from hand production to commercially applicable mixing and coating processes.
- Submitted revised Hydrogen Safety Plan.

Introduction

Typical DMFC systems use bulky condensers and other heat exchangers to recover water at the system level. These system components occupy a large volume and weight within the system design and have a significant impact on the system power and energy density. The UNF passive water recovery MEA (Figure 1) has been designed to incorporate

TABLE 1. Comparison of the status of the UNF 20 W DMFC power supply based on the passive water recovery MEAs optimized in this project versus the DOE technical targets for portable fuel cell power supplies.

Characteristic	Units	UNF 15 W DP3 2008 Status	DOE 2010 Target	UNF Proposed 20W System Design
Specific Power ^a	W / kg	35	100	41.5

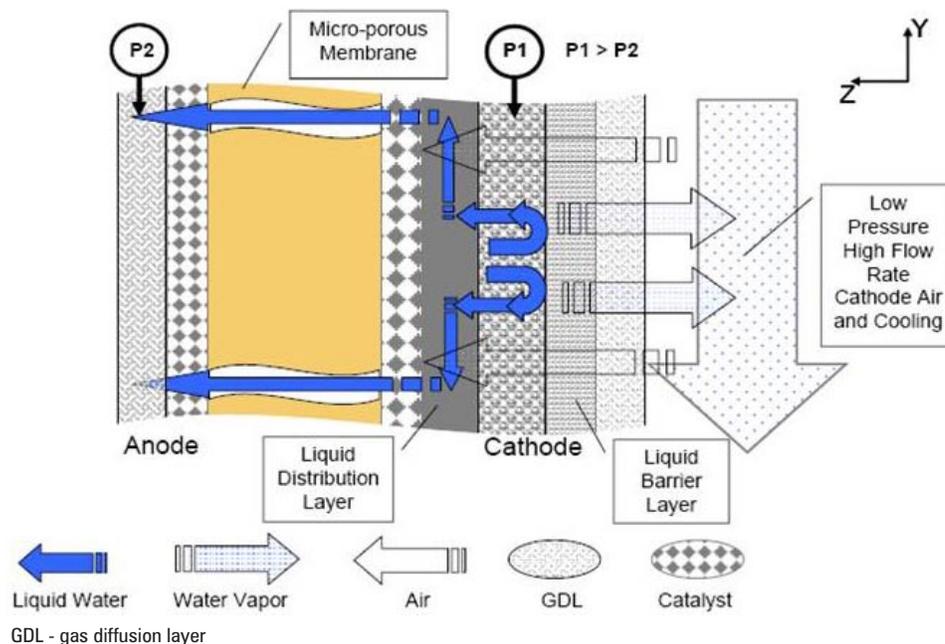

FIGURE 1. Water Transport Characteristics Optimized to Internally Recycle Water to Anode Compartment

novel passive water recycling features within the MEA to provide water recovery and management. This approach enables a significant simplification and miniaturization of the DMFC at the system level and facilitates substantial progress towards the DOE goals for power and energy density in small portable power systems. This progress has been demonstrated in the UNF system design.

Approach

The approach is to optimize the performance of the UNF passive water MEA and transition the technology to commercially viable processes, thereby lowering the cost and increasing the durability of the MEA. The MEA performance will be improved through better anode catalysts

and optimization of the cathode barrier layer water retention capability. By improving the anode catalyst structure to enhance the stability of the ruthenium, the MEA durability will be significantly enhanced. Optimizing the cathode barrier layer parameters will maximize the oxygen content at the cathode catalyst and thus improve the MEA performance.

Scale up of the manufacturing process for the MEA layers is expected to enhance both performance and reliability as well as reduce the overall cost. Optimizing the manufacturing process will move beyond the prototype operation by developing a batch manufacturing process which will improve the MEA-to-MEA reproducibility, increase the durability, and reduce the cost of the overall MEA. The methodology also includes an evaluation of the MEA produced at both the single cell and the system level against system operating conditions required for a small compact DMFC system developed in a related project at UNF.

Results

The UNF baseline passive water recovery MEA design has been successfully transferred to Johnson Matthey. The baseline process for the liquid barrier layer is based on a tedious multilayer, hand painted process to obtain the key water retention properties of water and oxygen diffusion and retention while recycling the liquid water to the cathode. Research during the past year has optimized the formulation and mixing process to enhance the barrier layer reproducibility, as well as improve control of the key barrier layer properties. Johnson Matthey has incorporated dual centrifuge mixing, a commercially applicable, scalable batch mixing processes, to replace the small scale ultrasonic mixing used in the baseline process. The formulation and processing has been further optimized to provide highly reproducible barrier layers leading to excellent MEA-to-MEA reproducibility in short stack testing.

The baseline ink application process requiring layer-by-layer hand painting has been scaled up to a commercially applicable automated coating process. This approach has now introduced rod coating where an excess of the coating is deposited onto the substrate. The wire-wound metering rod, sometimes known as a Meyer Rod, allows the desired quantity of the coating to remain on the substrate. The amount of material deposited is determined by the diameter of the wire used on the rod and the solids loading and viscosity of the coating solution. Using a large diameter wire on the metering rod and optimization of the coating ink characteristics has reduced the number of coatings required, improved reproducibility and reduced production costs. Single layer coatings (Figure 2) with good surface coverage and uniformity have been produced showing comparable baseline performance in MEA testing compared to the multilayer hand painted liquid barrier layers.

MEA durability is a critical factor in system durability. An extensive investigation and optimization of the MEA, liquid barrier layer and catalyst layer production has been

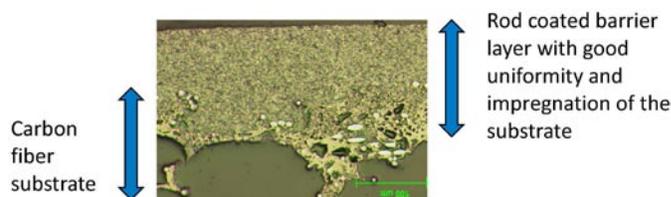

FIGURE 2. Cross-Section of Single Layer Barrier Layer Coating

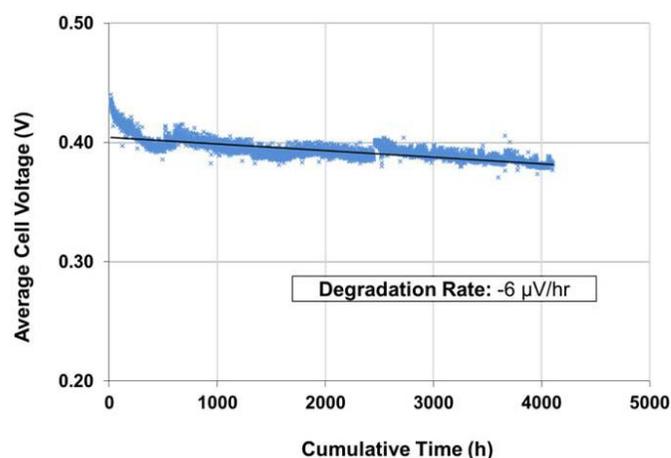

FIGURE 3. Passive water recovery MEAs show excellent durability under continuous operation. Eight cell stack operating at 120 mA/cm², 50°C, and 0.8 M methanol.

conducted in order to remove impurities and optimize the performance and durability both in the on-state as well as the off-state. The current MEA design exhibits excellent durability in continuous operation tests achieving over 4,000 hours of operation in an ongoing test (Figure 3). However, off-state testing has revealed significant degradation. Ex situ analysis of degraded MEAs indicated the presence of an organic impurity in the cathode catalyst structures. Optimization of MEA fabrication methods and improved operating parameters has led to a significant reduction of the quantity and influence of organic impurities. Testing has now shown a substantial reduction in the off-state degradation to acceptable levels for system operation and life.

Anode stability is a particular concern for long-term durability due to the loss of ruthenium from the anode. To address this issue, an ultra-stable ternary anode catalyst has been developed by project partners which incorporates a third metal to both stabilize the ruthenium and enhance the catalyst activity. This new catalyst provides improved durability and a reduction of cost at the system operation level. Project personnel are now in the process of scaling up the production of these catalysts for MEA testing. Additionally, the testing of commercially available catalysts has led to an improved anode catalyst showing significantly improved durability in methanol starvation accelerated testing.

Conclusions and Future Directions

Research conducted during the past year has:

- Successfully scaled up the passive water recovery MEA and improved the MEA-to-MEA reproducibility.
- Produced MEAs with excellent durability with projected life of over 5,000 hours of operation life.
- Identified significant steps in lowering the off-state durability by optimizing both the MEA fabrication and the operational parameters such that the overall MEA durability is in acceptable range for long term operation of the fuel cell system.

Future efforts include:

- Optimization of manufacturing techniques and formulations for the liquid barrier layer to maximize performance and durability.

- Improve MEA performance:
 - Optimization of the cathode structures for water management and power density.
 - Optimize the anode for durability and performance in the passive water recovery MEA.
- Optimization of the fuel cell operational parameters of startup, shut down and operation to maximize MEA performance and durability over the system operating life.
- Continued MEA durability testing to evaluate durability under a range of in-specification and out-of specification conditions.

established by DOE for portable fuel cell systems; assure path to large-scale fabrication of successful materials.

Individual objectives of this research are as follows:

- Synthesize and thoroughly evaluate direct methanol fuel cell (DMFC) anode catalysts with enhanced activity, reduced cost and improved durability.
- Design and implement in fuel cells innovative electrode structures for better activity and durability of portable power systems.
- Develop new hydrocarbon membranes based on (i) multiblock copolymers and (ii) copolymers with cross-linkable end-groups to assure lower MEA cost and enhanced fuel cell performance.
- Develop novel electrocatalysts and evaluate viability of portable power systems based on fuels alternative to methanol: ethanol and dimethyl ether.

Technical Barriers

This project addresses the following technical barriers from the Fuel Cells section (3.4.4) of the Fuel Cell Technologies Multi-Year Research, Development and Demonstration Plan: Planned Program Activities for 2005-2015 [1]:

- (A) Durability (catalysts and electrode layers)
- (B) Cost (catalysts and MEAs)
- (C) Performance (including fuel oxidation kinetics and the impact of fuel crossover on cathode performance)

Fiscal Year (FY) 2011 Objectives

The main objective of this project is to:

- Develop advanced materials (catalysts, membranes, electrode structures, membrane electrode assemblies [MEA]) and fuel cell operating concepts capable of fulfilling cost, performance, and durability requirements

Technical Targets

Portable fuel cell research in this project focuses on DOE's technical targets specified in Table 3.4.7 (Consumer Electronics) of the Multi-Year Research, Development and Demonstration Plan [1]. Table 3.4.7 defines DOE's Fuel Cell Technologies Program 2010 targets (soon to be modified).

Table 3.4.7 Technical Targets: Consumer Electronics (sub-Watt to 50-Watt)				
Characteristic	Units	2005 Status ^{a, b}	2006	2010
Specific power	W / kg	20	30	100
Power density	W / L	20	30	100

Cost	\$ / W	40 ^c	5	3
Lifetime	hours	>500	1,000	5,000

^a First year for which status was available.

^b Unless otherwise noted, status is based on average of available data.

^c Fuel Cell Seminar Abstracts, 2004, p. 290.

Using DOE's Table 3.4.7 solely as guidance relevant to the portable power system as a whole, we have devised the following specific technical targets for the project:

- System cost target: \$3/W
- Performance target: Overall fuel conversion efficiency (η_{Σ}) of 2.0-2.5 kWh/L
- In the specific case of a DMFC, the above assumption translates into a total fuel conversion efficiency (η_{Σ}) of 0.42-0.52, corresponding to a 1.620-fold improvement over the state of the art (ca. 1.250 kWh/L). Assuming fuel utilization (η_{fuel}) and balance-of-plant efficiency (η_{BOP}) of 0.96 and 0.90, respectively (efficiency numbers based on information obtained from DMFC systems developers), and using theoretical voltage (V_{th}) of 1.21 V at 25°C, the cell voltage (V_{cell}) targeted in this project can be calculated as:

$$V_{\text{cell}} = V_{\text{th}} [\eta_{\Sigma} (\eta_{\text{fuel}} \eta_{\text{BOP}})^{-1}] = 0.6-0.7 \text{ V}$$

Thus, the ultimate target of the materials development effort in the DMFC part of this project is to assure an operating single fuel cell voltage of at least 0.6 V. Very similar voltage targets have been calculated for the fuel cells operating on the two other fuels, ethanol (EtOH) and dimethyl ether (DME).

FY 2011 Accomplishments (in the first nine months of the project)

- Activity of “thrifed” PtRu catalyst of methanol (MeOH) oxidation significantly increased, much above that defined by an interim 2011 mass activity target of 200 mA/mg_{Pt}.
- PtRu-nanotube catalysts demonstrated with high specific MeOH oxidation activity.
- Lower MeOH permeability and better DMFC performance than that of Nafion[®] shown with hexafluoro bisphenol A benzonitrile-biphenyl sulfone (6FPAEB-BPS100) multiblock copolymers.
- PtRhSnO₂ electrocatalysts with unprecedented activity for ethanol oxidation designed, synthesized and demonstrated in electrochemical cell.
- Highest ever performance of gas-fed direct dimethyl ether fuel cell (DDMEFC) demonstrated with a Pt₅₀Ru₅₀ anode catalyst at 80°C.

Introduction

This multitask, multi-partner project targets advancements to portable fuel cell technology through the development and implementation of novel materials and concepts for (i) enhancing performance, (ii) lowering cost, (iii) minimizing size, and (iv) improving durability of fuel cell power systems for consumer electronics and other

mobile and off-grid applications. The primary focus of the materials research in this project is on electrocatalysts for the oxidation of MeOH, EtOH, and DME, on innovative nanostructures for fuel cell electrodes, and on hydrocarbon membranes for lower cost of the MEA and enhanced fuel cell performance (fuel crossover, proton conductivity). In parallel with new materials, this project targets development of various operational and materials-treatment concepts, concentrating among others on improvements to the long-term performance of individual components and the complete MEA.

Approach

The two primary research goals of this project are (i) the development of binary and ternary catalysts for the oxidation of MeOH, EtOH, and DME and (ii) synthesis of hydrocarbon polymers (multiblock copolymers, copolymers with cross-linkable functional groups) for lower cost and better fuel cell performance through reduced fuel crossover and increased protonic conductivity. Better understanding of the key factors impacting the performance of both catalysts and polymers is also pursued through a major characterization effort including X-ray absorption spectroscopy, X-ray photoelectron spectroscopy, nuclear magnetic resonance (NMR), and transmission electron microscopy (TEM).

Development of new catalysts and polymers is closely tied to novel electrode nanostructures tailored to minimize precious metal content, maximize mass activity, and enhance durability. The electrode-structure component of the effort concentrates on two groups of materials: (i) solid-metal nanostructures (e.g., nanowires and nanotubes) and (ii) carbon-based nanostructures acting as metal catalyst supports.

In addition to short-term testing and initial performance assessment, the catalysts, membranes, supports, electrode structures, and membrane-electrode assemblies developed in this project are subject to long-term performance (durability) testing. Performance limiting factors and degradation mechanisms are being identified and, if possible, addressed. Fabrication and scale up of viable catalysts, membranes, and supports is also being tackled through collaboration between partners in this project.

Results

DMFC Catalysts — New methanol oxidation catalysts were developed through “thrifing” of Pt in the binary PtRu catalysts. As shown by the anode polarization data in Figure 1, the “advanced MeOH catalyst” matched the performance of a benchmark HiSPEC[®] 12100 catalyst used at a much higher loading. The mass activity of 550 mA/mg_{Pt} was reached at 0.35 V (80°C), exceeding by 175% the interim 2011 mass-activity target (200 mA/mg_{Pt} at 0.35 V; orange star in the Figure 1). The anode catalyst research using the “thrifing” approach is on track to reach the project goals of 200 mA/mg_{Pt} at an anode potential of 0.25 V (Figure 1;

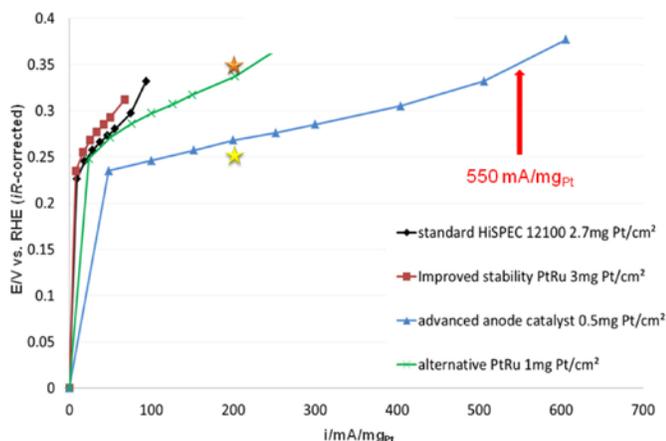

FIGURE 1. DMFC anode polarization plots recorded with three “Pt-thrifted” PtRu catalysts and a benchmark HiSPEC® 12100 PtRu catalyst in 0.5 M MeOH at 80°C.

yellow star) and 150 mA/cm² in a DMFC MEA at a voltage of 0.60 V.

In addition to the performance testing, the newly developed DMFC catalysts were subject to stability testing under cyclic voltammetry (CV) conditions. An increase in the Pt-character was observed during the first 200 cycles (0.0-0.85 V, 20 mV/s, 80°C), with virtually no change thereafter. 300 CV cycles resulted in 20-30 mV fuel cell performance loss at 0.50 V, attributable to the anode (based on the anode polarization data).

Innovative Electrode Structures — PtRu nanotube catalysts of MeOH oxidation were obtained using (i) displacement of Ag in an Ag nanowire template to form PtNT, followed by Ru deposition and reduction via a chemical method, followed by annealing to form a PtRu alloy; (ii) displacement of Ag in an Ag nanowire template to form PtNT, followed by electrochemical deposition of Ru; and (iii) simultaneous displacement of Cu in a Cu nanowire template to create PtRuNT, followed by annealing to form a PtRu alloy. Scanning electron microscope (SEM) and TEM images of Cu nanowires and PtRu nanotube catalysts, obtained using the last of the three methods, are shown in Figure 2.

Excellent specific activity for MeOH oxidation was demonstrated with several PtRuNT catalysts, with the onset potential of methanol oxidation of 0.33 V matching the one measured with a state-of-the-art commercial catalyst (HiSPEC® 12100). However, the mass activity of PtRu nanotube catalysts was relatively low.

Multiblock Copolymers for Reduced MeOH Crossover — Partial fluorination of a hydrophobic block was used to enhance proton conductivity via better phase separation and to improve adhesion (intactness) to the Nafion® ionomer used in the electrodes. In turn, benzonitrile was employed to reduce MeOH permeability via complexation reaction

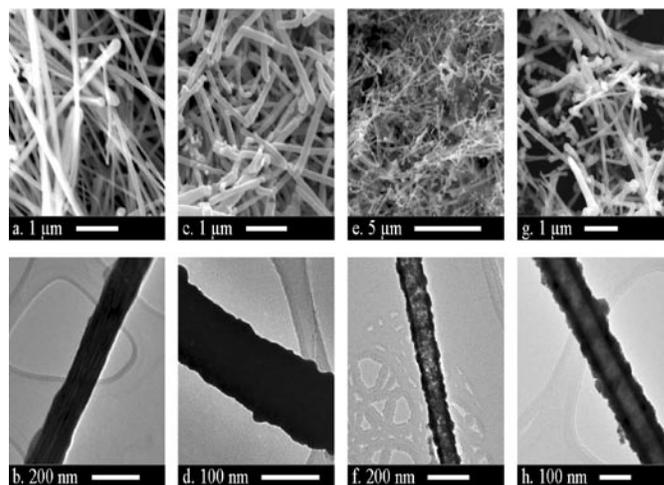

FIGURE 2. Top: SEM images of (a) CuNW; (c) PtNT; (e) Pt₈₀Ru₂₀; (g) Pt₅₀Ru₅₀. Bottom: TEM images of (b) CuNW; (d) PtNT; (f) Pt₈₀Ru₂₀; (h) Pt₅₀Ru₅₀.

with H₂O molecules, and highly-sulfonated hydrophilic block was used to increase proton conductivity. ¹H-NMR confirmed the intended chemical structure of the multiblock copolymer. Higher water uptake (undesirable) and proton conductivity (desirable) than in random copolymer were observed with multiblock copolymer. By controlling the block length of multiblock copolymers improved conductivity was achieved while maintaining the level of water uptake similar to that of random copolymers.

Good adhesion of multiblock-copolymer membranes and Nafion®-bonded electrodes was observed during MEA processing and in DMFC testing. MeOH permeability of multiblock-copolymer membranes was found to be three times lower than that of Nafion®, allowing for the use of thinner membranes. As a result, multiblock-copolymer membranes were found to outperform Nafion® 117 in DMFC testing, even at a relatively low MeOH concentration of 0.5 M MeOH (Figure 3). Even larger improvement relative to Nafion® is expected at higher MeOH concentrations.

EtOH Oxidation Catalysts — The effort here focused on the development of ternary catalysts, PtRhSnO₂ in particular. The ternary PtRhSnO₂ catalyst was found capable of oxidizing EtOH to CO₂ thanks to its multifunctional character. In that catalyst, Pt assists in the abstraction and oxidation of H atoms; SnO₂ serves as a source of OH for the oxidation of strongly bound intermediates; and Rh, placed either on SbO₂ or on Pt itself, aids in C-C bond scission. As a result of such an in-concert action of the three components, the optimized PtRhSnO₂ catalysts (Pt:Rh:Sn atomic ratios of 1:1/3:1 and 1:1/2:1) showed unprecedented activity in the oxidation of EtOH to CO₂ (Figure 4). The activity in complete oxidation of EtOH to CO₂ is especially evident at low potentials – a highly desirable property.

Other ternary catalysts were also studied, including PtIrSnO₂. The Ir-based ternary catalysts showed significant

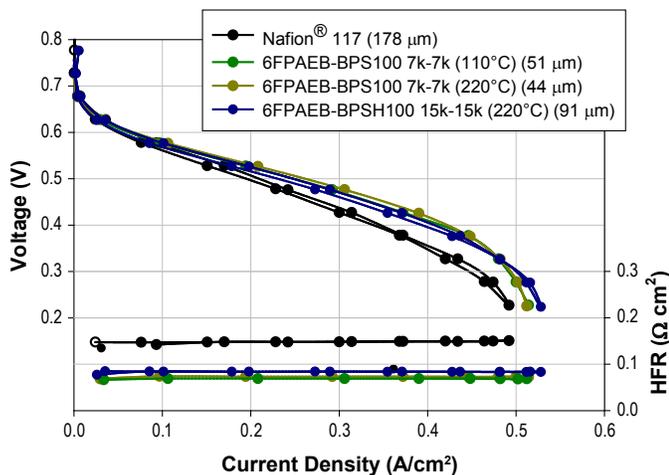

FIGURE 3. DMFC polarization and high-frequency resistance plots of MEAs using Nafion® and 6FPAEB-BPS100 multiblock copolymer membranes at 80°C. Numbers in parenthesis stand for the heat treatment temperature and membrane thickness. Anode: 6 mg/cm² Pt₅₀Ru₅₀ black, 1.8 mL/min 0.5 M MeOH solution; Cathode: 4 mg/cm² Pt black, 20 psig, 500 sccm air.

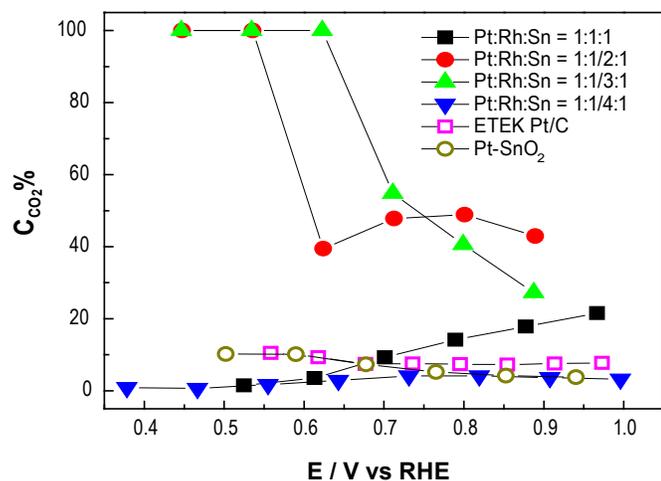

FIGURE 4. Carbon monoxide yields determined from infrared absorption spectra for four ternary PtRhSnO₂ catalysts, an Rh-free PtSnO₂ catalyst and a Pt/C reference catalyst from E-TEK.

activity in EtOH oxidation to acetic acid (CH₃COOH) but their selectivity for CO₂ formation was much lower than that of the best PtRhSnO₂ catalysts. Also studied were catalysts obtained via deposition of a Pt monolayer on gold single crystals, Au(111) in particular, these catalysts revealed promising activity in both EtOH and MeOH oxidation.

DME Fuel Cell Research — In general, DDMEFC exhibits lower performance than DMFC with MEAs optimized for methanol (but not yet for DME). DDMEFC performance was found to strongly depend on pressure but not much on the fuel flow rate (40-200 sccm; 5 cm² test cell). A wide range of Pt-to-Ru atomic ratios was screened

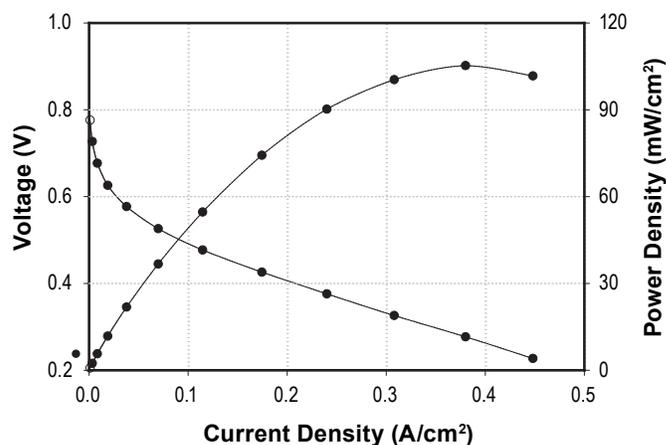

FIGURE 5. DDMEFC polarization and power density plots at 80°C. Anode: 6 mg/cm² Pt₈₀Ru₂₀ black, 40 sccm DME gas, 30 psig; Cathode: 4 mg/cm² Pt black, 20 psig, 500 sccm air; Membrane: Nafion® 117.

for DME anode performance for the first time. Although a Pt₅₀Ru₅₀ catalyst exhibited overall the best performance in high and middle voltage ranges, Pt-rich catalysts performed better at low voltages (near peak power), together attesting to a behavior much more complex than that of DMFC anode catalysts.

The above limitations notwithstanding, careful optimization of the anode catalyst and DDMEFC operating conditions allowed the achievement of a specific power density in excess of 100 mW/cm² (Figure 5). In spite of using gaseous DME feed, this result represents the best performance ever published for a DDMEFC at 80°C, surpassing that of Im et al. [2].

PtRu anode deactivation was found to occur at high potentials, likely due to the surface oxide formation (more oxophilic and thus less active surface). Fuel crossover experiments revealed much lower DME oxidation current at the cathode than that of MeOH, especially at higher potentials, indicating lower DME crossover and possibly inactivity of the oxidized Pt surface in DME oxidation.

Conclusions

- Selected “thrifty” PtRu catalysts of MeOH oxidation meet and significantly exceed 2011 interim mass activity target for methanol oxidation (200 mA/mg_{Pt}); PtRu nanotube catalysts exhibit promising methanol oxidation activity, however, mass activity needs to be increased by, for example, thinning tube walls.
- Ternary PtRhSnO₂ electrocatalysts of EtOH oxidation show unprecedented activity for ethanol oxidation, producing large amounts of CO₂; ternary catalysts with a Rh-to-Pt ratio between 1:3 and 1:2 exhibit the highest activity in EtOH oxidation; an increase in the catalyst particle size may be required for efficient EtOH adsorption and dehydrogenation; Au represents

potentially promising support for EtOH and MeOH oxidation catalysts.

- Multiblock copolymers with improved mechanical properties and high proton conductivity show lower MeOH permeability and better DMFC performance than Nafion[®]-based membranes.
- Unlike in MeOH oxidation, the optimal PtRu catalyst composition varies depending on the operating voltage of the DME fuel cell (anode potential); DME crossover is less than that of MeOH under typical testing conditions; a DDMEFC operating with a Pt₅₀Ru₅₀ anode catalyst has shown the highest performance reported to date at 80°C.

Future Directions

- MeOH Oxidation Catalysis: Perform comprehensive activity and stability study of advanced MeOH oxidation catalysts versus HiSPEC[®] 12100 as a benchmark; complete evaluation of PtSnX catalysts for upcoming Go/Go-No decision on PtSn catalysts in FY 2012; evaluate the degree of Ru crossover resulting from advanced MeOH oxidation catalysts.
- Innovative Membranes and Electrode Structures: Determine durability of multiblock copolymers in an operating fuel cell; reduce polymer water uptake; improve dimension control and eliminate oxidation of CuNW (before galvanic displacement); significantly reduce wall thickness of PtRu nanotubes to at least double the catalyst surface area.
- EtOH Oxidation Catalysis: Increase the size of PtRh nanoparticles to enhance the size of Pt ensembles in PtRhSnO₂ catalyst and thus facilitate adsorption and dehydrogenation of the EtOH molecule; scale up the synthesis of a selected ternary catalyst to 2 g per batch for MEA testing; evaluate Au clusters and/or supported Au-monolayers as catalyst supports; complete differential electrochemical mass spectroscopy instrument set up.
- DME Research: Determine the effect of anode catalyst composition on Ru crossover and cathode performance (relevant to both DDMEFC and DMFC); complete half-cell DME studies with PtRu catalysts; assess DDMEFC feasibility versus DMFC following full optimization of the DME anode (Go/No-Go decision on DME research in FY 2012).

Project Start Date: September 1, 2009

Project End Date: August 31, 2011

Fiscal Year (FY) 2011 Objectives

- Reduce or eliminate the small amount of gold used in TreadStone's current corrosion resistant metal plate technology for polymer electrolyte membrane (PEM) fuel cell applications.
- Develop the low-cost metal bipolar plates using commercially available low-cost carbon steel or aluminum as the substrate materials.
- Optimize the fabrication process for large scale manufacture.
- Demonstrate TreadStone's low-cost metal plate technology in the applications of portable, stationary and automobile fuel cell systems.

Technical Barriers

This project addresses the following technical barriers from the Fuel Cells section of the Fuel Cell Technologies Program Multi-Year Research, Development and Demonstration Plan:

(A) Durability

(B) Cost

(C) Performance

Technical Targets

The focus of this project is to further develop TreadStone's proprietary corrosion resistant metal plate technology reducing the metal plate cost to <\$3/kW, while still meeting the performance requirements. There are a number of performance requirements for PEM fuel cell bipolar plates. The most challenging requirements for metal bipolar plates are summarized in Table 1. The status of TreadStone's low-cost metal plates is summarized in the table as well.

TABLE 1. TreadStone's Metal Plate Status and DOE Targets

Parameter	Unit	TreadStone 2010 Status	DOE Targets	
			2010	2015
Plate Cost ^a	\$/kW	\$3.82	5	3
Plate Weight ^b	kg/kW	<0.4	<0.4	<0.4
Corrosion Anode ^c	μA/cm ²	not available	<1	<1
Corrosion Cathode ^d	μA/cm ²	<0.01	<1	<1
Resistance ^e	Ohm cm ²	<0.01	<0.02	<0.02

^a Based on 50% utilization of active area on the whole plate surface, stainless steel (SS) foil cost at historical average of \$2/lb, 1 W/cm² power density and projected 500,000 stacks per year production.

^b Based on the 0.1 mm thick SS foil.

^c pH 3, 0.1 ppm hydrofluorhydric acid (HF), 80°C, peak active current <1X10⁻⁶ A/cm² (potentiodynamic test at 0.1 mV/s, -0.4 V to +0.6 V (Ag/ AgCl)) de-aerated with Ar purge.

^d pH 3, 0.1 ppm HF, 80°C, passive current <5X10⁻⁸ A/cm² (potentiostatic test at +0.6 V (Ag/AgCl)) for at least 24 hours, aerated solution.

^e Includes contact resistance (on as-received and after potentiostatic experiment) measured.

FY 2011 Accomplishments

- Completed the low-cost, gold free conductive vias development. Demonstrated the processing technologies for carbon nanotubes and conductive carbides as the conductive vias. The corrosion current of metal plates with these vias are below 1 μA/cm² in pH 3 H₂SO₄ + 0.1 ppm HF solution under 0.8 V normal hydrogen electrode (NHE) at 80°C.
- Completed the large fabrication-scale cost analysis of metal plates using the gold-free vias technologies.
- Developed the processing technology and the identified the coating materials for aluminum substrate for PEM fuel cell applications.
- Demonstrated the current gold dots metal plates in portable and stationary applications, operating at ambient pressure conditions, with a small (30 cm² active

area of each cell) 200 W and a large (267 cm² active area each cell) 1 kW stack, respectively.

- Demonstrated 1,000 hours stable operation of the gold dots metal plate in a 300 cm² active area, 10-cell, 2.5 kW short stack under durability testing cycle (including the Federal Test Procedure [FTP] cycle along with others) to mimic the automobile real world driving conditions at Ford Motor Company.

Introduction

It has been reported that using metal bipolar separate plates can reduce the PEM fuel cell stack weight and volume by 40-50%, comparing with current graphite-based bipolar plates [1]. The major barrier to use metal bipolar plates in PEM fuel cells is the severe corrosion condition during stack operation. Most metals do not have adequate corrosion resistance in a PEM fuel cell environment, which results in rapid performance degradation due to the formation of the electrically resistive surface oxide scale, and potential contamination of the membrane electrode assembly by the dissolved ions from the metal plates. Various corrosion protection techniques have been investigated to prevent the metal plate corrosion in PEM fuel cell environments [2-7]. Some of these technologies have developed corrosion-resistant metal plates that can meet the performance requirements. However, it is still a challenge to have the metal bipolar plate that can meet both the performance and cost requirements. The focus of TreadStone's project is to develop corrosion resistant metal bipolar plates at the low-cost to meet DOE's 2015 targets.

Approach

Most research on metal bipolar plates has been focused on covering the whole plate surface with an electronically conductive and corrosion-resistant material to protect the metal from corrosion and maintain the electrical conductance of the metal. The challenge of this approach is that there is only a limited number of low-cost materials that can meet electrical conductivity and corrosion resistance requirements for PEM fuel cell applications. In addition, the processing required to apply these materials on metal substrate is either difficult or at high cost.

TreadStone takes a different approach to develop metal bipolar plates for PEM fuel cell applications. It was found that it is unnecessary to have the whole surface electrically conductive to ensure the low contact resistance (interfacial contact resistance < 10 mΩ.cm²) between bipolar plates and the gas diffusion layer (GDL). TreadStone's approach is based on this principle, as shown in Figure 1.

The majority of the metal surface area is covered with the low-cost corrosion-resistant but non- (or poor) conductive material (purple layer in Figure 1). A corrosion

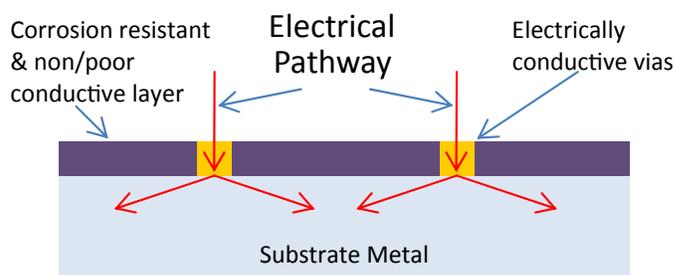

FIGURE 1. Schematic Drawing of TreadStone's Corrosion Resistant Metal Plate Design

resistant and highly electrically conductive material (such as Au) forms the paths for electron transport, in the form of small conductive vias (yellow bars) penetrating through the non-conductive layer. Electrons generated from the anode reaction will flow through the GDL to the conductive vias (illustrated as red arrows) passing through the metal plate to the other side for the cathode reaction on the cathode of the adjacent cell. The conductive vias, having a dimension as small as several micrometers, are distributed on the metal surface. The average distance between the conductive vias is 20-70 μm. The dense distribution of conductive vias ensures a uniform current distribution between the GDL and metal bipolar plates.

TreadStone's approach is unique because it uses only a small portion (<1-2%) of the plate surface for electrical contact. It was found that more than 500,000 via/in² cover the metal plate surface as the electrical contact point of metal plate with GDL, when small (<5 μm) conductive vias are used. It is because of the high amount of the contact points that enable the low contact resistance of metal plates.

Results

TreadStone's current metal bipolar plate uses a small amount of gold as the electrical contacting material in the form of conductive vias, and SS as the substrate material. In this project, we plan to develop a lower cost material to reduce the gold usage, or replace gold as the contact material. We have finished the process development to use a palladium/gold composite as the contact materials. We also developed the process to use carbon nanotubes and conductive carbides as the conduct material. All of the approaches have met the performance requirements. Figure 2 shows the scanning electron microscope (SEM) picture of the chromium carbide particles that are bonded on the SS surface using chromium-nickel alloy.

The large-scale fabrication cost analysis of the metal plates using alternative conductive vias was conducted based on a post-forming coating process. The assumptions of the cost analysis are based on 50% utilization of active area on the whole plate surface, stainless steel foil cost at historical average of \$2/lb, 1 W/cm² power density and projected 500,000 stacks per year production. The fabrication flow

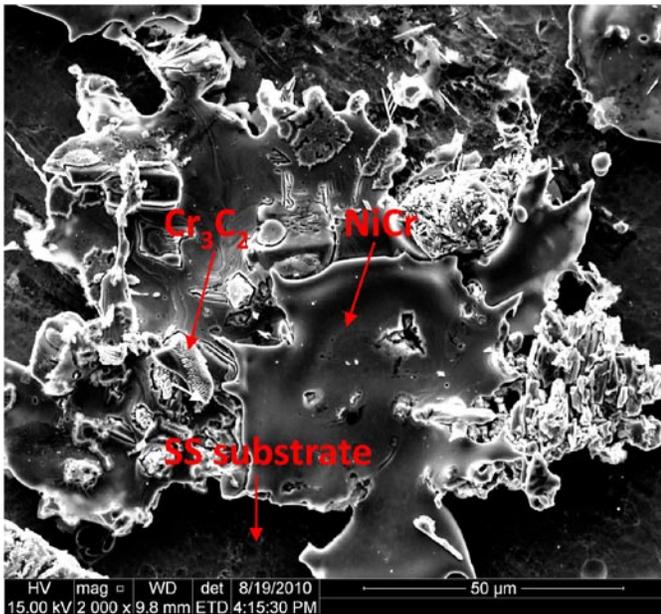

FIGURE 2. SEM Picture of Chromium Carbide Particles Bonded on SS Substrate

TABLE 2. TreadStone Metal Plate Large-Scale Fabrication Cost Components

Process Step	316 SS foil	Forming	Coating		
			Pd/Au	C-tube	Carbides
Cost ¹	\$0.75	\$0.48	\$0.31	\$0.79	\$0.30

¹ The cost is \$/plate, based on 400 cm² active area on each plate.

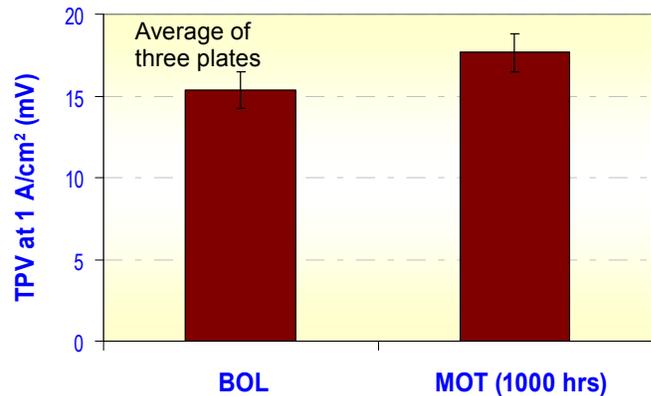

FIGURE 4. Comparison of the TPV Drop of TreadStone’s Metal Plates before and after the 1,000 hr Stack Durability Test under Dynamic Loading Conditions at Ford

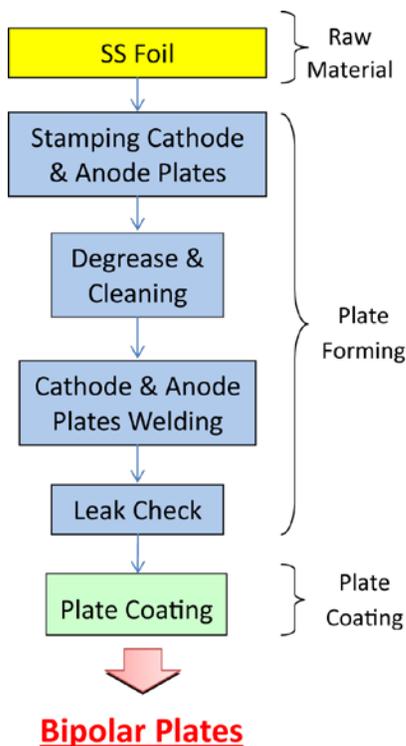

FIGURE 3. Fabrication Flow Diagram for Cost Analysis

diagram is shown in Figure 3. It includes the raw material (SS foil), bipolar plate forming step, and coating step. The cost of each portion is listed in Table 2.

Table 2 shows that metal plate coating cost using TreadStone’s technology can be as low as \$0.30/plate, which is a minor part of the bipolar plate cost. SS substrate material cost is the major cost item that accounts of ~50% of the total plate cost, even using the commercial available lower cost 304 SS foil. The metal forming (including laser welding and leak checking) cost is very high as well. Therefore, using lower cost substrate materials, such as carbon steel or aluminum substrate is very useful to reduce the bipolar plates cost. Alternative, low-cost forming process is also important for the low-cost bipolar plate production.

The stacks using TreadStone’s metal plates have been designed, and optimized for portable, stationary and automobile applications. The portable power stack has 30 cm² active area on each cell. The peak power is 200 W. The stationary stack has 263 cm² active area on each cell. The peak power is 1 kW. The initial performance of these two stacks has been characterized. The long-term durability tests of the stacks are underway.

A 10-cell, 2.5 kW short stack for automobile application has also been assembled and tested at Ford Motor Company. The stack has 300 cm² active area on each cell, and operates under high pressure. The stack is being tested for utilizing durability cycle (which includes the FTP cycle along with others) mimicking “real-world” driving conditions. After finishing 1,000 hours of stable operation, the stack was disassembled for inspection of all components. There was no sign of corrosion of the metal plates after the 1,000-hour test. The comparison of the through-plate voltage drop

(TPV, under 1 A/cm²) before beginning of life (BOL) and after the middle of test (MOT) for the 1,000 hours durability test is compared in Figure 4. The TPVs meet the DOE's requirement (<20 mV), although there is small increase (from 15 mV to 18 mV) after the test.

Conclusions and Future Directions

TreadStone's unique corrosion-resistant metal bipolar plates have demonstrated stable operation for PEM fuel cell applications in portable, stationary and automobile applications. The processes can reduce the metal plate coating cost to as low as \$0.30/plate. Further development will be focused on:

- Scale up of the lower cost conductive vias processing technique for the large-scale production.
- Demonstration of the low-cost carbon steel and aluminum plates based bipolar plates.
- Demonstration of the long-term operation stability of the TreadStone's low-cost metal plates in PEM fuel cell applications.

Fiscal Year (FY) 2011 Objectives

- Develop a fluoropolymer-inorganic filler composite coating that is electrically conductive and provides a physical barrier to corrosive species within the fuel cell.
- Apply the composite coating to aluminum alloy substrates using an established high-volume manufacturing process.
- Measure the corrosion resistance at 80°C and area specific resistance of the composite coated aluminum plates.
- Apply the composite coating to stamped and welded bipolar plates, and then conduct a single cell, 2,000-hour test.
- Conduct an analysis to determine the anticipated cost of manufacturing the plates at high volume.

Technical Barriers

This project addresses the following technical barriers from the Fuel Cells section of the Fuel Cell Technologies Program Multi-Year Research, Development and Demonstration Plan:

- Durability
- Cost
- Performance

Technical Targets

The goal of this work is to develop an aluminum-based bipolar plate that meets all of the DOE technical targets for bipolar plates shown in Table 1. This goal will be met by applying a composite coating that is both electrically conductive and corrosion resistant to the aluminum plate, using an established high-volume manufacturing process.

TABLE 1. Project Progress Toward Meeting DOE Technical Targets for Bipolar Plates [1]

FY 2011 Accomplishments

- Nano-size titanium carbide (TiC) powder has been synthesized using a low-cost process that is scalable.
- A patent application has been filed for the low-cost CaB₆ powder synthesis procedure.
- TiC was identified as the most acid resistant of the cermet powders tested for acid stability and electrochemical stability at 80°C and room temperature in sulfuric acid solutions.
- Substituting nano-size TiC for half of the flake graphite filler in the composite coatings was found to significantly reduce area specific resistances of the coated aluminum samples.
- The composite coated aluminum plates meet the DOE target for electrochemical corrosion resistance under cathodic conditions at 80°C.
- Composite-coated, stamped aluminum plates were made using wet spraying, a high volume manufacturing process.

- A composite-coated, stamped aluminum plate tested in a single-membrane electrode assembly (MEA), two-bipolar plate cell test showed improved performance over untreated aluminum.

Introduction

Aluminum bipolar plates offer a potential weight reduction over stainless steel, while still having the desired mechanical properties that a metal offers. Furthermore, untreated aluminum can meet all of the DOE bipolar plate targets except for corrosion resistance. To overcome this one weakness, the project team has been applying a composite coating consisting of a matrix of an acid-resistant fluoropolymer and a filler material that is electrically conductive and acid-resistant. Metal carbides, metal borides, metal silicides, and carbon-based materials, such as graphite, carbon black, and carbon fibers, were identified as candidate filler materials based on reported electrical conductivity and acid resistance properties [2]. In the first year of the project, we found that metal borides were not stable under simulated fuel cell conditions, so in the second year, TiC and titanium disilicide (TiSi₂) were evaluated. The composite-coated aluminum bipolar plates have been being fabricated using techniques, such as stamping, welding, and spraying, that are currently used for high-volume manufacturing of many consumer goods. In the second year of the project, we have focused on meeting the corrosion and electrical properties targets.

Approach

The titanium carbide powder currently available commercially is expensive and not available in sub-micrometer sizes. So, titanium carbide was made at Southern Illinois University (SIU) using a low-cost process that produces nano-size particles [3]. Acid stability tests at 80°C and electrochemical stability tests in sulfuric acid were conducted to determine if TiC and TiSi₂ are durable enough for use in proton exchange membrane (PEM) fuel cells. Argonne has worked on identifying the formulation of fluoropolymer and filler that can provide the desired electrical conductivity in a composite coating. We have sprayed fluoropolymer (ethylene-tetrafluoroethylene, EFTE, or polychlorotrifluoroethylene, PCTFE) mixed with TiC, graphite, and/or carbon black onto non-conductive substrates, and we have measured the surface conductivity/resistivity of these samples. We have varied the ratio of graphite to TiC, the type of fluoropolymer, and the ratio of filler to fluoropolymer to increase the electrical conductivity of the coatings. We have conducted electrochemical corrosion studies of the coated aluminum samples at 80°C using the conditions specified by the DOE. Finally, initial tests were conducted of stamped, welded, and coated aluminum plates in a single cell test.

Results

Of the metal carbides, TiC was chosen because it has the desired combination of reported electrical conductivity, density, and corrosion resistance [2]. Low-cost processes were used to synthesize nano-size TiC powder at SIU. These processes allowed for tuning the electrical properties of the powder. Inexpensive TiO₂ and propylene precursors were used in the 2-step synthesis procedure, which used processing temperatures of up to 1,500°C. Powder X-ray diffraction results showed only the desired titanium carbide phase. Analysis by scanning electron microscope (SEM) showed that particle sizes were, on average, <200 nm in diameter, Figure 1, and that the particles formed an interconnected network.

The environment inside a PEM fuel cell is acidic due to the presence of the Nafion[®] membrane and the Nafion[®] ionomer in the electrodes, combined with the humidity [4]. Acid stability tests were conducted on the synthesized TiC, graphite (Superior Graphite), and TiSi₂ at 80°C in 3.5% H₂ in helium for 30 days. The sulfuric acid solution used in the tests was 0.001M H₂SO₄ (pH=3) with 0.1 ppm NaF. The results of the tests are shown in Table 2. The values shown in the “% Sample Remaining” column were calculated from the measured change in the weight of the samples.

Electrochemical corrosion experiments using the thin-film rotating disk-electrode technique were also conducted on the TiC and TiSi₂ powders to corroborate the findings of the acid stability tests. Powders of TiC (SIU) and TiSi₂ (Aldrich, ball milled) were made into an ink by mixing them

with Nafion[®] and an organic solvent. The volume ratio of the powder to dry Nafion[®] was 50:50. A thin film of the mixture was applied to a rotating disk electrode (RDE) and electrochemically tested at room temperature in both O₂-saturated and O₂-free (Ar-purged) 0.1 M H₂SO₄. The loading of powder on the RDE was 155 µg/cm². Potential holds at several potentials and potential scans relevant to the bipolar plate application were run. The results are shown in Table 3. The TiSi₂ sample performed the best with no redox features observed in the cyclic voltammetry (CV) tests. The TiC was acceptable, but a small oxidation peak at 0.56 V occurred when cathodic scan went to a potential less than 0.4 V. Since these tests were performed at room temperature there are some differences from the acid stability experiments. Based the results from the two types of stability tests, TiC was chosen as the best candidate, along with graphite and carbon black, for the filler phase in the composite coatings.

TABLE 3. Results of RDE Electrochemical Stability Experiments

Sample	Corrosion Current (A/cm ²)			Observations
	0.84 V in Ar	0.84 V in O ₂	0.14 V in Ar	
TiC (SIU)	6.24 x 10 ⁻⁶	1.34 x 10 ⁻⁵	7.06 x 10 ⁻⁶	A small oxidation peak at 0.56 V occurred when cathodic scan went to a potential less than 0.4 V.
TiC (Aldrich, milled)	4.92 x 10 ⁻⁵	2.87 x 10 ⁻⁵	2.27 x 10 ⁻⁵	Same features as for unmilled SIU TiC
TiSi ₂ (Aldrich, milled)	5.65 x 10 ⁻⁶	5.70 x 10 ⁻⁶	4.75 x 10 ⁻⁶	No obvious redox features

Surface electrical conductivity/sheet resistance were measured using the Van der Pauw technique [5] and a four-point probe (Jandel) on the composite coatings deposited on non-conductive ceramic substrates. Through-sample area specific resistivity (ASR) measurements [6,7] were conducted at an applied pressure of 200 psi on aluminum-based samples that were coated on both sides. Slurries were made by ball milling the desired amounts of filler (graphite, nano-size TiC, and/or carbon black) and fluoropolymer (PCTFE or ETFE) with solvents. The slurries were then sprayed onto either aluminum or ceramic substrates and sintered at 240 to 300°C for 2 to 4 h. Selected ASR and

sheet resistance results are shown in Table 4. The measured electrical conductivities of the composites were significantly lower than the published bulk conductivities of the fillers possibly because the fluoropolymer may act to separate the filler particles as it flows between the particles during sintering. The coatings that have lower ASR tend to also have higher surface resistance. This may be due to the even distribution of the fillers into the bulk of the coating versus segregating onto the surface.

TABLE 4. Selected Results of Surface and Through-Plane Electrical Conductivity Measurements of Composite Coated Samples

Coating Composition		ASR (Ω-cm ²)	Sheet Resistance (Ω)
Vol % Fluoropolymer	Vol% Filler(s)		
40% PCTFE	60% Graphite	0.68	4.2
40% PCTFE	40% Graphite, 20% Carbon black	0.97	3.3
40% PCTFE	30% TiC, 30% Graphite	0.27	8.4
50% PCTFE	25% TiC, 25% Graphite	0.11	25
50% PCTFE	50% Graphite	3.3	5.0
50% ETFE	25% TiC, 25% Graphite	0.58	27
50% ETFE	50% Graphite	2.7	20
40% ETFE	60% Graphite	0.75	2.8

Corrosion resistance of coated aluminum samples was measured using electrochemical methods [7] to evaluate the ability of the coatings to provide a physical barrier between the aluminum substrate and the corrosive media in a fuel cell. In these experiments, conducted at 80°C, the electrolyte was 0.001M sulfuric acid (pH= 3) with 0.1 ppm NaF. For cathodic corrosion tests, air was bubbled continuously through the acid solution and a potential of 0.6 V vs. Ag/AgCl (0.8 V vs. normal hydrogen electrode, NHE) was applied for 24 h. For anodic corrosion tests, argon was continuously bubbled through the acid solution and a potential of -0.4 V vs. Ag/AgCl (-0.2 V vs. NHE) was applied for 24 h. The results for aluminum plates with a coating of 25 vol% TiC/25% graphite/50 vol% EFTE applied by spraying at Orion Industries are shown in Figure 2. The corrosion current densities for the cathodic tests were below the DOE corrosion target, however, the anodic corrosion current densities were higher than the DOE target.

A total of 75 uncoated aluminum bipolar plates with flow fields have been stamped with a 60 cm² active area. The design is based on the GTI patented trapezoidal flow field structure for PEM fuel cells with very low pressure drop. The hydrogen permeability of the formed plates was tested and the results did not show any detectable hydrogen pass-through at 50 psig (3.4 atm), meeting the DOE target. In addition, the cell design was proven during fuel cell testing, and it showed that the stacks can be well sealed against fuel, oxidant, and cooling water leaks. In order to improve electrical conductivity through the samples GTI has

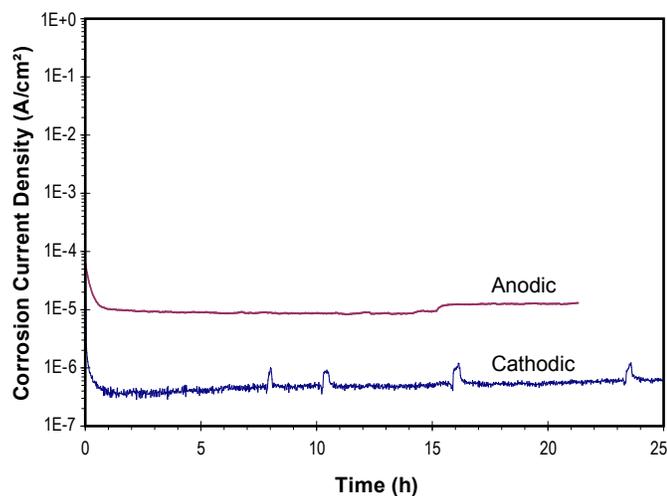

FIGURE 2. Electrochemical Corrosion Test Results for 25% TiC/25% Graphite/50% ETFE on Aluminum Panels Produced by Orion

developed surface treatments that deposit a small amount of metal on the surface of the aluminum before the coating is applied. Two of these treated and coated stamped aluminum plates have been tested in a single-MEA, two-bipolar plate cell at 50°C using a Gore MEA fed with hydrogen and air. The results are shown in Figure 3 and compared to the results obtained with untreated aluminum bipolar plates. The treated and coated aluminum bipolar plates performed better compared to the untreated aluminum bipolar plates. This is because the uncoated aluminum plates had formed a resistive oxide layer on the surface, whereas it was removed and prevented from forming on the treated and coated bipolar plates. Figure 4 shows a photograph of the stamped and coated aluminum plates.

Conclusions and Future Directions

- Composites made with a combination of flake graphite and nano-size titanium carbide as the filler have the highest electrical conductivities.
- These coatings provide adequate corrosion protection under cathodic conditions.
- Coatings from Orion will be made thinner and with a higher fraction of conductive filler to improve electrical properties.
- Aluminum surface treatments will be evaluated for improved conductivity and corrosion resistance.
- A different fluoropolymer will be evaluated for its potential to improve anodic corrosion resistance.
- A manufacturing cost analysis will be conducted.

Technical Targets

This project is conducting fundamental aspects of anion exchange membrane fuel cell (AMFCs) for practical use in intermediate (10-50 kW) power applications. Insights gained from these studies will be applied toward the next stage of development of AMFC systems. Since there were no technical targets for AMFCs in the current DOE Fuel Cell Technologies Program, we have proposed the technical targets based on state-of-the-art alkaline fuel cells/materials in the original proposal (2008). Key technical targets, and FY 2011 and 2012 statuses are shown in Table 1.

FY 2011 Accomplishments

- Synthesized highly conductive (0.1 S/cm), chemically stable (>700 h) and mechanically robust poly(phenylene) (PP)-based anion exchange membranes.
- Prepared stable hydrocarbon and perfluorinated-based guanidinium functionalized ionomers having electron donating spacer.
- Measured the oxygen reduction reaction (ORR) kinetics of non-Pt catalysts (Ag, Ni, Pd, and carbon) with KOH and guanidinium electrolytes.
- Demonstrated H₂/O₂ and H₂/air alkaline membrane fuel cell performance at various operating conditions and under steady-state extended term operating conditions.

Fiscal Year (FY) 2011 Objectives

- Synthesize highly conductive and stable anion exchange membranes.
- Prepare highly gas permeable perfluorinated ionomers for electrode layers.
- Develop non-precious metal catalysts for oxygen reduction reactions.
- Demonstrate single-cell performance of alkaline membrane fuel cells.
- Perform an extended term alkaline fuel cell test under steady state conditions.

Technical Barriers

This project addresses the following technical barriers from the Fuel Cells section (3.4.4) of the Fuel Cell Technologies Program Multi-Year Research, Development and Demonstration Plan:

Introduction

Current quaternary ammonium-tethered anion exchange polymer electrolytes do not show enough stability under alkaline conditions due to the chemical degradation under highly pH conditions. Furthermore, ionomer used in electrode layers has limited gas permeability that

TABLE 1. Technical Targets and FY 2011 and 2012 Status for the Project

significantly reduces cell performance [1]. In FY 2010, we demonstrated successful synthesis of stable guanidinium functionalized poly(arylene ether)s and initiated synthesis of perfluorinated ionomers for the catalyst layers. In FY 2011, continuing efforts to develop new anion exchange polymer electrolytes and electro-catalysts have been made in order to demonstrate the performance and stability of AMFCs.

Approach

Our approach to achieve high performance AMFCs is to develop new materials which have improved properties and minimal interference between them when the materials are used in membrane electrode assemblies (MEAs). Sandia National Laboratories investigated the properties of PP-based anion exchange membranes for practical use in AMFCs. LANL continued to develop the guanidinium functionalized ionomers for the catalyst layer, which have electron donating stabilizers which may provide good cation stability under high pH conditions. The Jet Propulsion Laboratory (JPL) and LANL investigated the catalytic activity of various catalysts in guanidinium solution in order to screen the best class of catalysts for alkaline membrane fuel cell systems. Extensive efforts on fabrication of AMFC MEAs and fuel cell testing were performed at LANL in order to demonstrate good AMFC performance. The ultimate goal for these approaches is to realize good AMFC performance by integration of these materials into an MEA.

Results

Anion Exchange Polymer Electrolytes

Mechanical properties for both poly(ether sulfone) (PES)- and PP-based anion exchange membranes were investigated as a function of exposure to high pH conditions

in order to gain some insight into the practicality of using these polymers in AMFCs (Figure 1). The PES membranes showed a surprising diminishment of both elongation (strain) and strength (stress) after just 30 minutes in 0.5 M NaOH at 80°C. These effects become more pronounced with increases in both NaOH concentration and temperature, indicating that they are due to degradation of the polymer backbone and not simply the exchange of bromide anions (in the control) for hydroxide anions. This indicates that PES-based polymers lack the chemical stability required for them to be used in AMFCs, an important result given that several recently reported anion exchange membranes and ionomers are based on similar PESs [2,3]. By contrast, the results for the PP-based membranes do not show a continual weakening of the mechanical properties with successive exposures to NaOH. An initial exposure to 0.5 M NaOH at 80°C for 1 hour does result in an elongation decrease of about 40% and a strength decrease of about 10%, but after conversion back to bromide ion form, the curve looks very similar to the control. A second NaOH treatment does not diminish the mechanical properties any more than the first treatment. Thus the shifting of the curves in Figure 1b is indicative of membrane property changes that are due to the identity of the anion present and not due to polymer degradation.

LANL continues to develop guanidinium functionalized ionomers for the catalyst layer. Guanidinium functionalized ionomers were synthesized via activated fluorinophenyl-amine reaction [4], followed by the methylation with dimethyl sulfate. The activated fluorine-amine reaction gives precise control of cation functionality without the deleterious side-reactions and allows the direct connection of guanidinium into stable phenyl rings. For perfluorinated ionomer, fluoroaniline or six-membered imides were used as electron donating spacers which reacted with perfluorinated carboxylic acid (equivalent

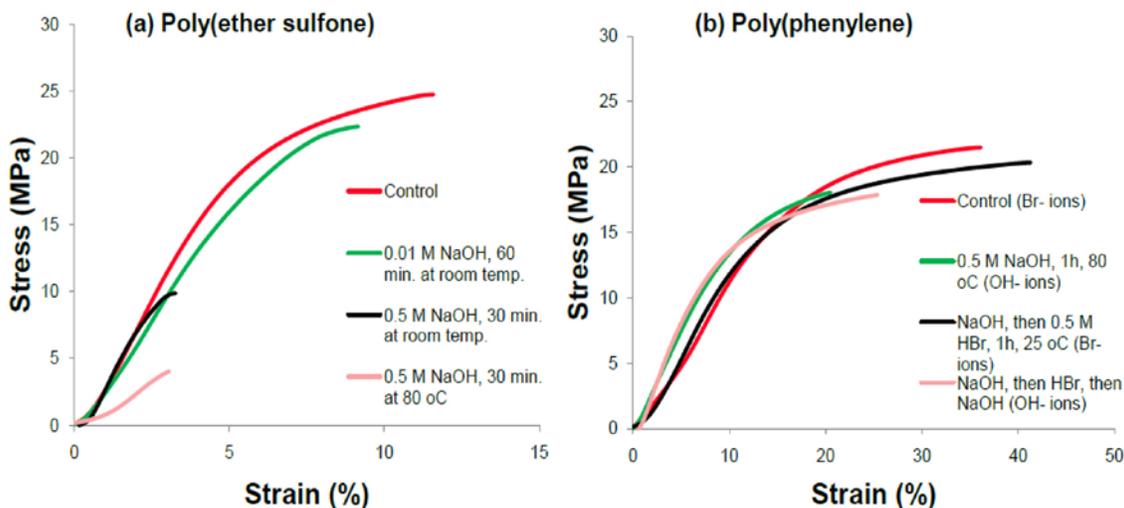

FIGURE 1. Mechanical test results at 50°C and 50% relative humidity for (a) PES-based anion exchange membranes and (b) PP-based anion exchange membranes.

weight=1100). The chemical stability of the ionomer with the electron donating spacers was much improved compared FY 2010 ionomer as it showed less than 10% degradation after soaking the membranes in NaOH solution at 80°C for 100 h. The solubility of the ionomer is good in aprotic solvents such as N-methylpyrrolidone, dimethyl acetamide and high alcohols such as glycerol.

Electro-Catalysts

JPL investigated the reaction kinetics of various electro-catalysts with KOH and guanidinium electrolytes. These experiments were conducted on Pt and Pd surfaces. The Pt surface exhibits H₂O redox processes in 0.1 M tetramethyl guanidine (TMG)_(aq) similar to those in KOH/NaOH electrolytes, and remains highly active for oxygen reduction. Electrochemical tests performed via rotating disk electrode (RDE) measurements on elemental Pt electrodes show that Pt exhibits the major electrochemical reactions: hydrogen evolution reaction (HER), hydrogen oxidation reaction (HOR), hydrogen adsorption and the ORR in 0.1 M TMG and 0.1 M KOH. Surface reconstruction and activity in KOH mirror that of Pt in acids, and in 0.1 M TMG, only (110) crystal plane is active after cycling to 1.1 V (vs. reversible hydrogen electrode, RHE). Electrochemical tests performed via RDE on elemental Pd electrodes show that Pd exhibits HER, H_{upd}, and ORR in 0.1 M TMG and 0.1 M KOH. The ORR current density (at 0.9 V RHE) for Pd surfaces in alkaline electrolytes exceeds that for Pt surfaces in acid solutions, as shown in Figure 2. Thus, Pd or Pd-based alloys are very attractive for use as the cathode in AMFCs. RDE tests on Pd are ongoing to examine potential dependence of surface reconstruction in KOH and TMG electrolytes. To date, in 0.1 M TMG, only (110) crystal plane is active after cycling to 1.1 V (vs. RHE). Our temporal tests have shown that the TMG electrolyte shows remarkable stability after two months, with some signs of

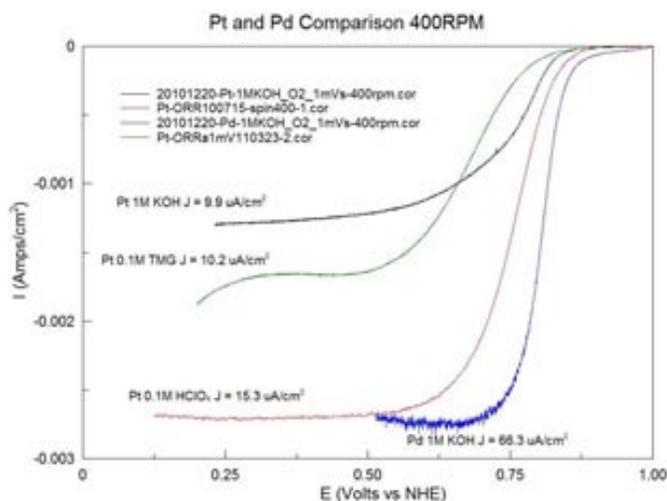

FIGURE 2. Oxygen reduction reaction curves for Pt and Pd surfaces in 0.1 M TMG and 0.1 M KOH electrolytes.

increasing resistivity such as the positive potential shift of the H-desorption peak. TMG and its byproducts can adsorb onto the Pt surface below ~0.8 V, obscuring the transition between typical kinetic and mass-limiting regions during oxygen reduction. This effect is especially pronounced at low rpm (low oxygen concentrations). Though the nature of TMG adsorption onto a polarized Pt electrode needs to be better understood, this study shows that free TMG can be used to support electro-catalytic activity on Pt, in place of NaOH or KOH salts. Because AMFCs require frequent replenishment of metal cation electrolyte to avoid precipitation of bicarbonates, the use of TMG electrolyte could still improve such systems despite its slow degradation. Particularly if it serves to better stabilize functional groups within the membrane, itself.

LANL developed nitrogen-doped carbon-based catalysts. The N-doped carbon-based catalysts showed promising ORR activities ca. half-wave potentials reached up to 0.95 V (vs. RHE) which is superior to the ORR activities of Pt/C catalysts in alkaline media (Figure 3). The durability of the N-doped carbon-based catalysts was measured during potential cycling (0.6-1.0 V vs. RHE) in O₂-saturated electrolytes. The ORR activities were enhanced after 1 k cycles and stabilized after 5 k cycles. The N-doped carbon based catalysts showed good ORR kinetics in guanidinium electrolytes. The onset potential (vs. RHE) of N-doped catalyst (0.2 mg/cm²) in guanidinium 0.1 M aqueous solution is 1.03 V which is same with the Pt/C catalyst (60 μg/cm²) in NaOH and higher than Pt/C in HClO₄.

Fuel Cell Performance

While MEA performance using newly developed catalysts is in progress, AMFC performance using a PP-based membrane, guanidinium functionalized ionomer

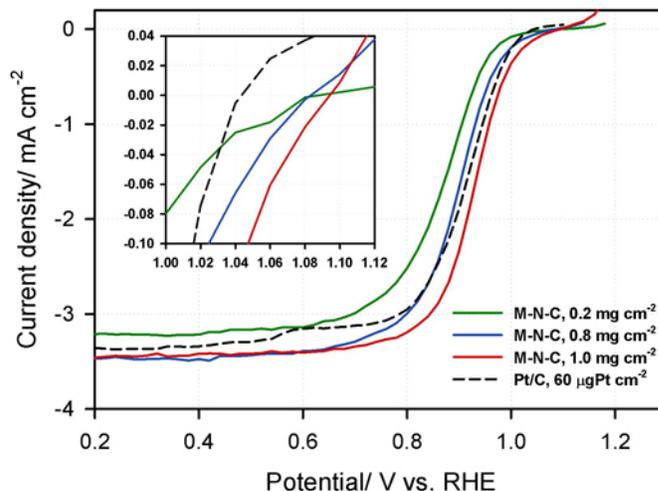

FIGURE 3. ORR activity of M-N-C catalysts in NaOH solution; RDE experimental conditions: 0.1 M NaOH; 900 rpm, room temperature; steady state potential (OCP, 120 s, 20 mV steps, 25 s/step)

and Pt black catalyst was measured under various conditions. The electrode composition and humidification were optimized. Degrees of anode flooding and cathode dehydration strongly depend on membrane and ionomer type and fuel cell operating conditions. After the optimization process, maximum power density of 500 and 300 mW/cm² was achieved for the MEAs at 80°C and under H₂/O₂ and H₂/air conditions, respectively (Figure 4). Much inferior performance was obtained when tetraalkyl ammonium functionalized poly(phenylene) polymers were used as electrode ionomer (e.g. maximum power density of 200 mW/cm² under H₂/O₂ condition). Guanidinium functionalized ionomer also showed promising durability during a 300 h AMFC operation at 60°C and constant voltage of 0.3 V. Tafel-slope of internal resistance-free polarization curves before and after lifetime test changed from 62.4 to 69.6 mV/decade (24 μV/dec h), indicating that minimal ionomer degradation occurred during the lifetime test while more than six times faster degradation rate was observed for tetraalkylammonium functionalized ionomer.

Conclusions and Future Directions

- Newly synthesized PP-based anion exchange membranes exhibited excellent chemical stability after immersion in 0.5 M NaOH solution. Stable guanidinium functionalized perfluorinated ionomers with electron donating spacer were prepared in liquid dispersion.
- Catalytic activities of Pt, Pd and N-doped carbon-based electro-catalysts showed excellent ORR kinetics in KOH and guanidinium solution. The N-doped carbon-based catalysts showed unprecedented activity (ca. half-wave potentials reached up to 0.95 V [vs. RHE]) in alkaline conditions.

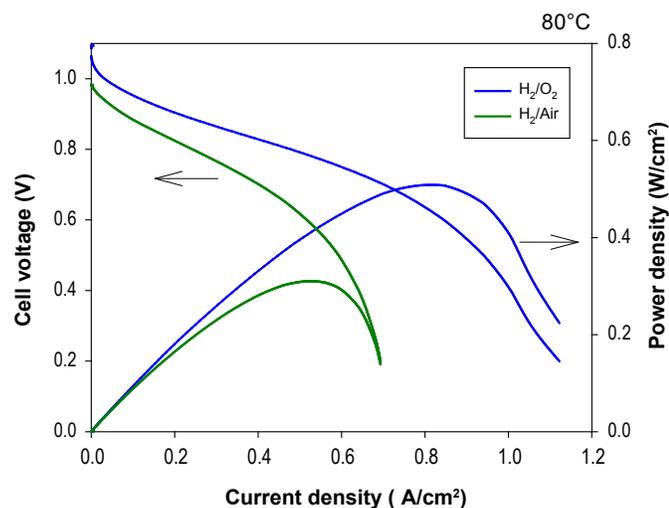

FIGURE 4. H₂/O₂ and H₂/air AMFC performance at T_{cell} = 80°C under fully hydrated conditions

- The maximum power density of alkaline membrane fuel cells under H₂/O₂ and H₂/air conditions reached to 500 and 300 mW/cm² which exceeded the project target performance. The preliminary extended term life test indicated that only minimal degradation of ionomer (24 μV/dec h) occurred during steady-state AMFC operation.
- AMFC performance tests using non-precious metal catalysts are yet to be assessed. Longer term test up to 800 h is under investigation.

Contract Number: DE-EE0000464

Project Start Date: October 1, 2009
Project End Date: September 30, 2011

- Operating current density of more than 300 mA/cm² in both SOFC and SOEC modes.
- Overall decay rate of less than 4% per 1,000 hours of operation.

Meeting those performance and endurance technical targets will be the key RSOFC cell stack technology development step towards meeting DOE's Technical Targets for Distributed Water Electrolysis Hydrogen Production by an RSOFC system.

FY 2011 Accomplishments

- Developed 12 candidate cell material systems, of which five systems exceeded both performance (area specific resistance [ASR] <0.3 Ω-cm²) and endurance (degradation rate less than 4% per 1,000 hours) targets in both fuel cell and electrolysis modes.
- Validated cell material systems through electrolysis/fuel cell cyclic operation. Over 100 daily cycles were demonstrated over 2,500 hours. The degradation rate is less than 1% per 1,000 hours.
- Completed stack design and component down select, conducted a kW-class RSOFC stack development test for over 5,000 hours.

Fiscal Year (FY) 2011 Objectives

The objective of project is to advance reversible solid oxide fuel cells (RSOFCs) cell stack technology in the areas of endurance and performance.

Technical Barriers

This project addresses the following technical barriers from the Hydrogen Production section of the Fuel Cell Technologies Program Multi-Year Research, Development and Demonstration Plan [1]:

- (G) Capital Cost
- (H) System Efficiency
- (I) Grid Electricity Emissions (for distributed power)
- (J) Renewable Electricity Generation Integration (for central power)

Technical Targets

Technical targets will be achieved through RSOFC materials development and reversible stack design. The project objectives are to meet the following performance and endurance targets in a kW-class RSOFC stack demonstration:

- RSOFC dual mode operation of 1,500 hours with more than ten SOFC/solid oxide electrolysis cell (SOEC) transitions.

Introduction

RSOFCs are energy conversion devices. They are capable of operating in both power generation mode (SOFC) and electrolysis modes (SOEC). RSOFCs can integrate renewable production of electricity and hydrogen when power generation and steam electrolysis are coupled in an "energy storage system" that can turn intermittent solar and wind energy into "firm power," or can enable intermittent power to aid in the selective arbitrage between peak power rates and power company resource deployment and turndowns. In order to address the technical and cost barriers, DOE funded a number of research projects over the past ten years [2]. Although significant progress was made in those projects, further development is required, especially in the areas of RSOFC performance and endurance. In this project, Versa Power Systems (VPS) is addressing performance and endurance issues for RSOFC cell and stack.

Approach

VPS has identified four task areas in an effort to improve the performance and endurance of RSOFC systems: degradation mechanism study, cell material development,

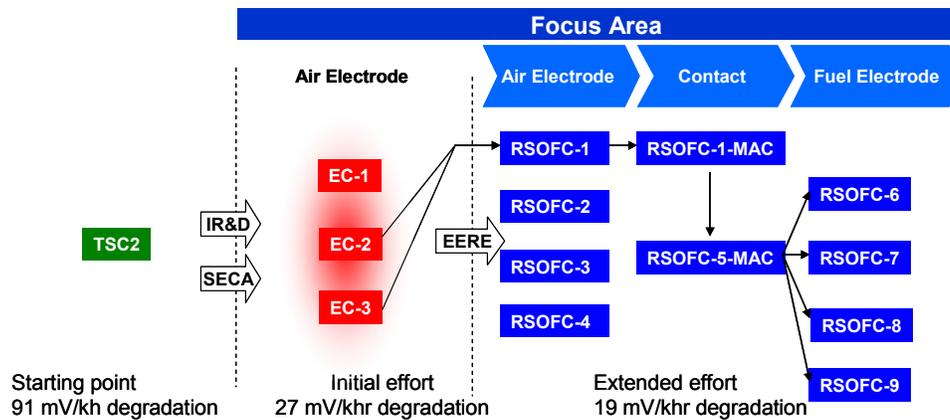

FIGURE 1. RSOFC Cell Development Path at VPS

interconnect material development, and stack design and demonstration. A stage-gate project management process is employed with a quantitative Go/No-Go decision point. The scope of the work has been carried out by:

- Building on VPS’ strong SOFC cell and stack baseline, and leveraging cell and stack advancements from the DOE Solid State Energy Conversion Alliance program.
- Carrying out parallel materials development activities and integrating them with cell production technology development.
- Conducting RSOFC stack and process designs to address durability, performance, and cost in both fuel cell and electrolysis operating modes.

Results

The development path for RSOFC cell technology at Versa Power Systems can be summarized in Figure 1. Twelve material systems have been developed in the project.

Table 1 summarizes the RSOFC cell technology at the project Go/No-Go decision point. The best cell material system—RSOFC-7—demonstrated 223 and 224 mΩ-cm² ASR values in electrolysis and fuel cell modes, respectively, at 750°C compared with the target of less than 300 mΩ-cm². The degradation rate of the RSOFC-7 in steady-state

TABLE 1. Summary of RSOFC Performance and Endurance Status at Project Go/No-Go Decision Point

	Target	Status
Performance (area specific resistance in both SOFC and SOEC operating modes)	<0.3 Ω-cm ²	0.223 Ω-cm ² in SOFC 0.224 Ω-cm ² in SOFC
Degradation (Overall decay rate)	<4% per 1000 hours of operation	~1.5% per 1,000 hours of operation
Operating Duration	>1,000 hours	1,005 hours (as of Oct. 29, 2010)
Operating Current Density	>300 mA/cm ²	500 mA/cm ²

electrolysis mode was 1.5% per 1,000 hours compared with a target of less than 4% per 1,000 hours for over 1,000 hours.

RSOFC cell material systems have been further developed in fuel cell/electrolysis cyclic operation. A cyclic test profile was designed and implemented to simulate an integrated reversible SOFC/solar power system. The test runs a 24 hour cycle with 10.5 hours in electrolysis, 12.5 hours in fuel cell operation, and the balance for transitions. Figure 2 depicts the cell voltage against time over 105 simulated day-night cycles of electrolysis and fuel cell operation. The performance decay, calculated from fuel cell mode, was 0.21 mV/cycle (0.89% per 1,000 hours) over 105 days (or cycles, representing over 2,500 hours).

A number of RSOFC stacks were built and tested in parallel for cell and interconnect materials development. A kW-class stack test (Figure 3) demonstrated over 5,000 hours of stable electrolysis operation with a split between constant current and constant voltage operation. This kW-class stack design and RSOFC-7 cell materials system have been chosen for the end-of-the-project stack metric test. The performance decay, calculated from fuel cell

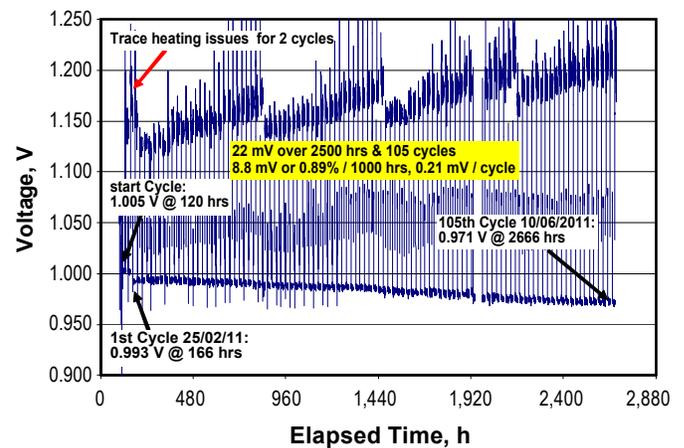

FIGURE 2. Fuel Cell and Electrolysis Cyclic Testing of a RSOFC-7 Cell

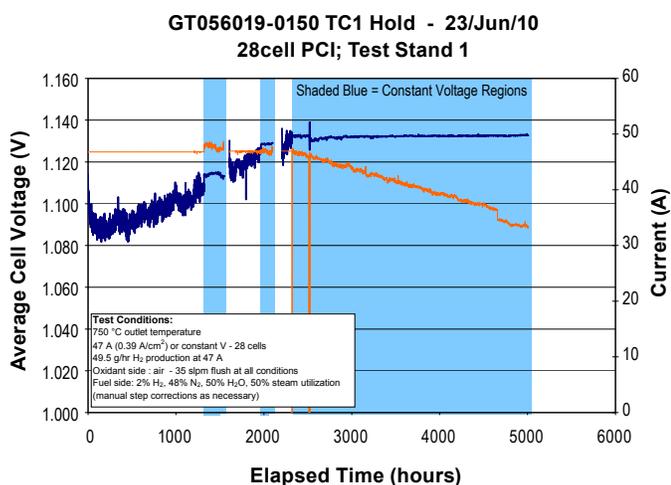

FIGURE 3. GT056019-0150 kW-Class Stack Electrolysis Tests in Both Constant Current and Constant Voltage (shaded blue) Conditions

mode, was 0.21 mV/cycle (0.89% per 1,000 hours) over 105 days (or cycles, representing over 2,500 hours). The test is on-going and will be updated as testing continues.

Conclusions and Future Directions

In the coming year, the project team will continue on the current development path. This work includes:

- Continuation of the RSOFC cell and stack development and testing.
- Completing the end-of-the-project kW-class RSOFC stack metric test.

Contract Number: DEEE0000465

Subcontractor:
dPoint Technologies, Inc.
Vancouver, British Columbia, Canada

Start Date: April 1, 2010
Projected End Date: September 30, 2012

FY 2011 Accomplishments

- Humidifier operating conditions for stationary, automotive and portable fuel cells have been established using input from manufacturers and other stakeholders.
- A range of humidifier membrane materials have been prepared and characterized.
- Permeance, air permeability and membrane durability testing for a range of humidifier membranes has been performed. One class of Gore prepared membranes has been identified as particularly promising.
- A room temperature static water vapor transport test protocol has been developed for rapid permeance testing and/or quality control of humidifier membranes.
- Humidifier cost modeling for the most promising candidate has been completed. The model shows acceptable high volume production costs for the most promising class of Gore prepared membranes.
- Initial module modeling and prototyping indicate that the composite Gore humidifier membrane will allow automotive module performance, size and durability targets to be met.

Fiscal Year (FY) 2011 Objectives

- Demonstrate a durable, high-performance water transport membrane.
- Build and test a compact, low-cost, membrane-based module utilizing that membrane for use in an automotive stationary and/or portable fuel cell water transport exchangers.
- Model and show high-volume costs associated with membrane and module.

Technical Barriers

This project addresses the following technical barriers from section 3.3, Fuel Cells, of the Fuel Cell Technologies Program Multi-Year Research, Development and Demonstration Plan in Task 7, “Develop balance of plant components”:

- (B) Cost
- (E) System Thermal and Water Management
- (A) Durability and (C) Performance: by allowing the fuel cell to operate in less harsh, more humid environments they will perform better and be more durable.

Introduction

Today it is essential to humidify the gases supplied to the fuel cell inlets for automotive and many stationary fuel cell stack designs. In this work, we are providing a new, inexpensive, composite membrane capable of very high water vapor transport and low air cross-over. The composite structure has been designed to allow lower total cost while still meeting automotive and stationary humidifier water transport and durability targets.

Because the transport rates of these new materials are so high, current planar membrane humidifier designs are not capable of fully utilizing the high rates. Therefore, the project is using an innovative, low-cost humidifier module with customized channel geometries that can take advantage of the high water transport rates. By having a materials development effort integrated with a humidifier module-system design and build program, we will be able to effectively exploit the improved material properties in an actual device.

Approach

Perfluorosulfonic acid (PFSA) membranes fulfill most of the requirements for the water transport media at the heart of the planar membrane water exchanger. They fall short

primarily on cost, and secondarily on durability, especially when they are made thin to increase performance and lower cost. W.L. Gore and Associates, Inc. (Gore) has developed a composite water vapor transport membrane that has overcome both of these limitations. The basic composite structure consists of a very thin ionomer layer sandwiched between two microporous polymer layers. The ionomer layer provides the active water transport and provides an impermeable layer to prevent gas cross-over. The water transport rate can be engineered to be very high either through the use of a material that has very high inherent water transport rates (e.g., PFSA polymers), or by making it extremely thin (e.g., $<5\ \mu\text{m}$). The microporous layer provides three critical features: first it protects the thin ionomer layer from mechanical damage during handling; second, it confers strength to the thin layer allowing it to be more durable during use; and third, it offers a strong, protective support layer for placement of a macroporous gas diffusion layer.

Our subcontractor, dPoint Technologies, has developed an innovative pleated planar membrane humidifier that is able to achieve automotive manufacturer water transport and pressure drop requirements. The pleated design utilizes existing low-cost, high-volume pleating equipment that is used to manufacture air filters for automotive and heating, ventilation and air conditioning applications. The pleated humidifier is a proven technology that dPoint has been developing in cooperation with several major automotive manufacturers. Further improvement in humidifier size, cost and performance is possible through the use of the Gore membrane and optimizing the flow field channel design to take full advantage of this new membrane.

Results

A range of composite membranes have been produced by Gore, including ionomers coated on microporous membranes, shown schematically in cross-section in Figure 1a, and “sandwich” structures shown schematically in Figure 1b. The ability to prepare very thin layers of an ionomer allows very high permeances to be achieved with these materials. For example, using an ~ 5 micron PFSA layer (Figures 1c and 1d) in a sandwich structure, described as GORE™ M311.05, permeances of close to two times the next best alternative (Figure 2), i.e., a 25 micron homogeneous PFSA membrane, are achieved. A high-volume cost model for this class of composite membranes has also been completed, and it shows that these materials can be produced for $\frac{1}{2}$ to $\frac{1}{3}$ the cost of the next best alternative homogeneous membranes [4].

Initial studies of the durability of the sandwich composite microstructures, e.g., M311, show virtually no performance degradation with time at 65°C (Figure 3), a temperature consistent with stationary and/or backup power systems. Studies at 80°C and above, where most automotive systems operate, are underway. Initial results at these higher temperatures indicate there may be some limited reduction in performance after long times, but the magnitude of the loss will be manageable through appropriate module design and sizing.

The design and prototyping of humidifier modules by dPoint Technologies is well underway. Using a finite element model, the module flow field and other design parameters have been optimized (Figures 4a and 4b). Several subscale modules, (Figure 4c), have been built

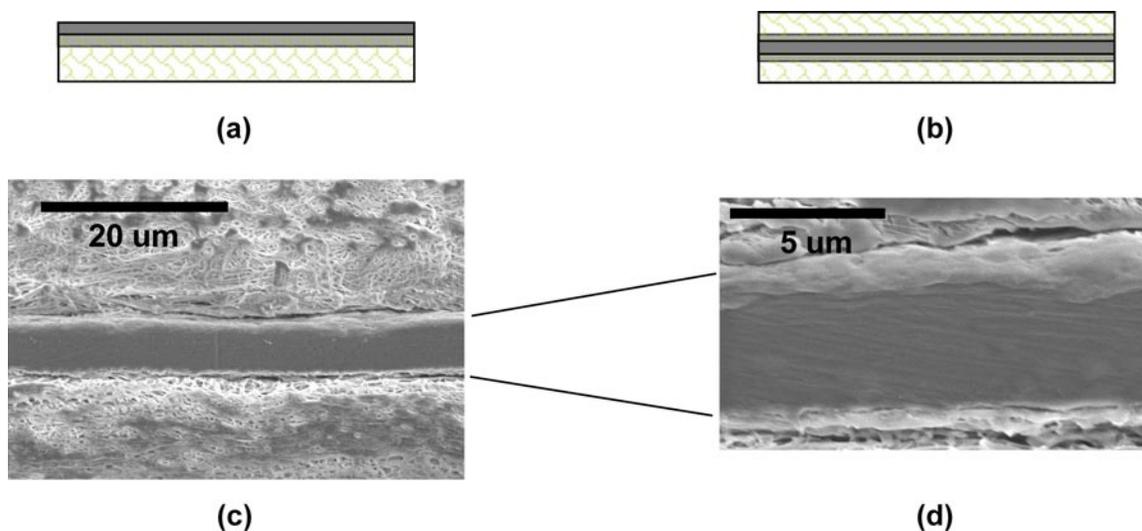

FIGURE 1. A range of composite membranes have been produced including ionomers coated on microporous membranes, shown schematically in cross-section in (a), and “sandwich” structures shown schematically in (b). One example of a “sandwich” composite structure is shown in a cross-sectional micrograph in (c). A higher magnification micrograph in (d) shows the ionomer layer is ~ 5 microns thick.

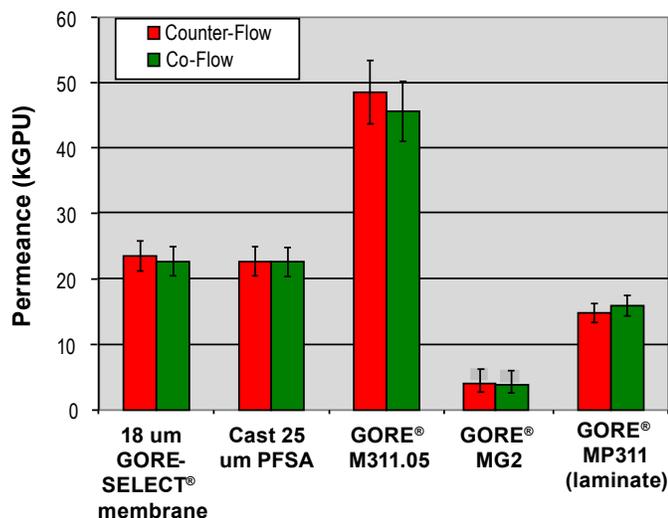

FIGURE 2. The permeance of a wide range of potential humidifier membrane materials has been measured using a dynamic permeance cell [1-3]. The results indicate the sandwich structures using PFSA ionomers, illustrated here by GORE™ M311.05, have permeances much higher than other potential alternatives. GORE™ MG2 is a hydrocarbon ionomer coated on a microporous substrate, while MP311 is an inexpensive hydrocarbon ionomer in a similar sandwich structure to M311.05.

using the designs identified by the modeling. The initial results from these subscale modules indicate that the high permeance Gore composite materials will allow modules to be built that have the requisite size and water transport characteristics required in demanding fuel cell automotive humidifier module applications.

Conclusions and Future Directions

- Water transport rates through GORE™ humidification membranes can be very high, especially for the fluorinated ionomer-based materials.
- A range of alternate materials have been prepared and water permeance and air-impermeability has been measured. Sandwich structures using thin PFSA layers offer the best combination of performance, durability and cost.
- A high-volume cost model has demonstrated that automotive cost targets can be met using the most promising Gore composite membranes.
- Initial module modeling and subscale prototypes show that using the high-performance Gore composite humidifier membrane will enable an automotive

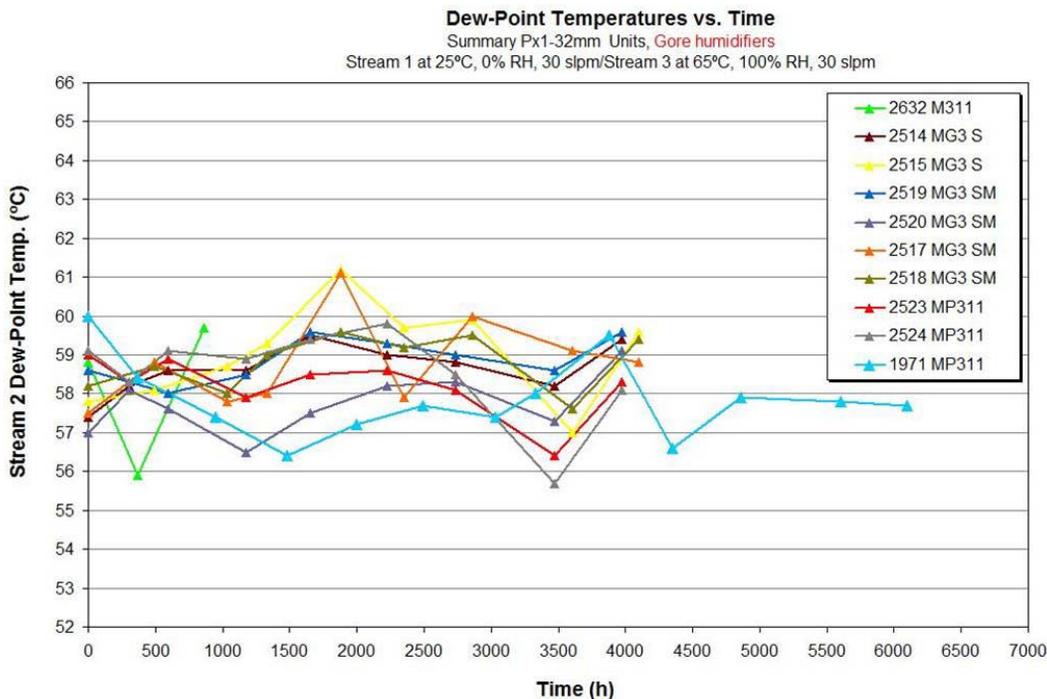

FIGURE 3. The performance of the composite humidifier membranes made in this program do not degrade with time under the conditions shown in this figure, where the stream 2 dew point temperature is the dew point of the dry outlet.

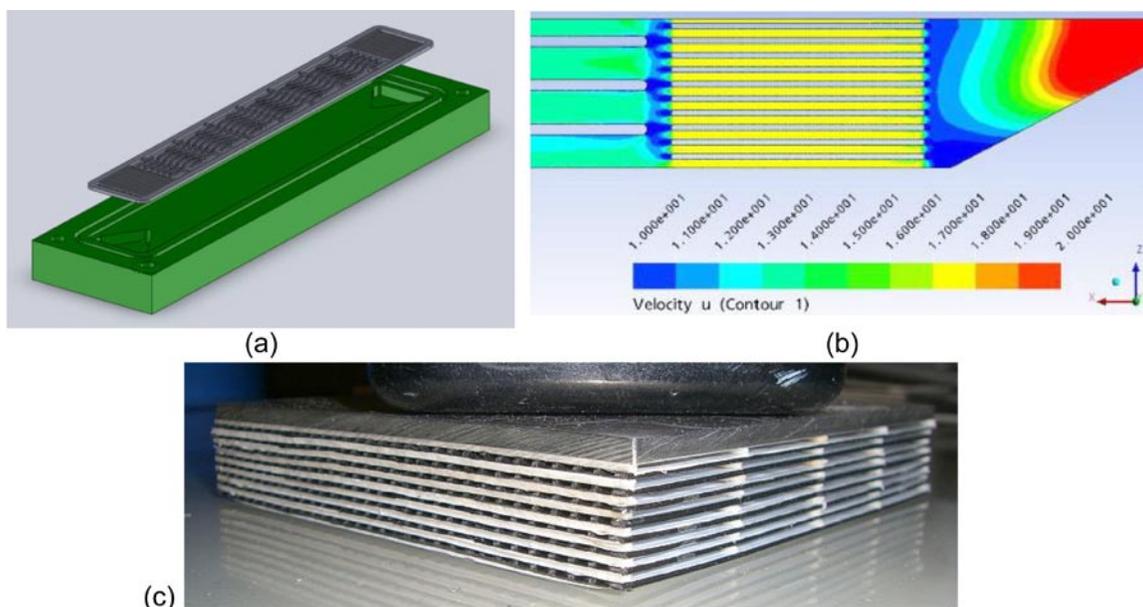

FIGURE 4. Using a finite element model of potential flow field geometries (a), the velocity contours, (b), have been used to optimize the module design. Several subscale modules, (c), have been built using several designs. The initial results indicate that the high permeance Gore composite materials will allow modules to be built that have the requisite size and water transport characteristics.

humidifier module that meets the demanding cost, durability and performance fuel cell automotive targets.

- In the final year of the project, the durability testing will be completed, the most promising membrane candidate and backer combination will be identified and scaled up, the best module design will be identified through further subscale tests, and a full-scale module will be built for DOE testing.

Contract Number: DE-FC36-03GO13109

Project Start Date: December, 2002
 Project End Date: December 30, 2011

Fiscal Year (FY) 2011 Objectives

- Develop an advanced heat exchanger (radiator) that can efficiently reject heat with a relatively small difference between fuel cell stack operating temperature and ambient air temperature.
- Test humidification systems to meet fuel cell inlet air humidity requirements. The moisture from the fuel cell outlet air is transferred to inlet air, thus eliminating the need for an outside water source.
- Reliability testing of select humidification system for 5,000 cycles.

Technical Barriers

This project addresses the following technical barriers from the Fuel Cells section of the Fuel Cell Technologies Multi-year Research, Development and Demonstration Plan:

(E) System Thermal and Water Management

Technical Targets

TABLE 1. Technical Targets for Proton Exchange Membrane (PEM) Fuel Cell Thermal and Water Management System

Characteristics	Units	Target	Honeywell Status
Humidity of PEM cell stack inlet air	% at 80°C	>60	50%
Cooling requirements with 85°C coolant temperature and flow rate of 2.5 kg/sec, with frontal area not to exceed 0.32 sq meter	kW	50	50
Radiator cost (by TIAX LLC) without markup	\$	58	50
Reliability of radiator	hrs	5,000	Under test
Total parasitic power (air fan + cooling pump)	kW	<2.4	To be determined

FY 2011 Accomplishments

- Thermal management portion of the project was successfully completed and the final test report for the thermal management was submitted to DOE in December 2009. The full-scale radiator performance test data was provided to Argonne National Laboratory for their fuel cell system model.
- Water Management
 - Full-scale and sub-scale membrane humidifier system was successfully tested. The water transfer efficiency was lower than the required 60%.
 - The enthalpy wheel-based humidification system and planer membrane-based humidity device testing is successfully completed; the test data is presented here.

Introduction

Balance-of-plant (BOP) components of a PEM fuel cell automotive system represents a significant portion of total cost based on the 2008 study by TIAX LLC, Cambridge, MA.

The objectives of this thermal and water management project are twofold:

- Develop an advanced cooling system to meet the fuel cell cooling requirements. The heat generated by the fuel cell stack is a low-quality heat (lower temperature) heat that needs to be dissipated to the ambient air. To minimize size, weight, and cost of the radiator, advanced fin configurations were evaluated.

- Evaluate air humidification systems which can meet the fuel cell stack inlet air humidity requirements. Four humidification devices were successfully tested, three based on membranes and the fourth based on a rotating enthalpy wheel. The lab-scale units, one membrane module and enthalpy wheel, have been successfully tested by the suppliers.

Approach

To develop a high-performance radiator for a fuel cell automobile, various advanced surfaces were evaluated including foam; advanced, offset, and slit louver fins; and microchannel with various fin densities. A value function was developed to evaluate and compare the cost of various fin geometry radiators. The value function based on the cooling system weight, performance, parasitic power, and initial cost. Two fin geometries -- 18 fins per inch (fpi) louver and 40 fpi microchannel -- were down-selected. The full-scale radiators were built and tested. The results were presented in annual progress report as well as final test report submitted in 2009.

A full and half-scale Nafion® membrane module, full-scale planar membrane module with Gore membrane and enthalpy wheel was designed, built and was tested to validate the performance. A test stand was designed and built, to test the humidification devices simulating the 80 kW fuel cell stack operating conditions. The test results for the first two systems were presented in previous reports. And the results for the last two systems (enthalpy wheel and planar modules) are presented in this report.

Results

The test results for the enthalpy wheel are presented in Figures 1 and 2. One of the variables unique to the enthalpy wheel is its rotational speed. The water transfer efficiency at three flow rates was measured as a function of rotational speed. In Figure 1 the water transfer ratio of humidity outlet stream (primary out) and inlet stream (secondary in) is plotted against the enthalpy wheel rotational speed. As expected the transfer efficiency improved with higher speed. The enthalpy wheel water transfer rate reaches over 70% above 30 revolutions per minute (RPM) at high flow rate. The water balance (in Figure 2) during high flow rate tests was under 10% which is exceptionally good, however at low flow rate and low speed the water balance was poor which may be attributed to measurement error. The water transfer rate for the enthalpy wheel was the best among all the four devices tested and it met the goal of 60% required for the PEM fuel cell.

Planar membrane water transfer and balance test data are presented in Figures 3 and 4, respectively. The water transfer rate varied from 20-37% with decreasing efficiency at high humidity levels. The water balance test results show the opposite trend where the water balance improved with high inlet humidity. The average water balance error

during entire water humidity range was about 15% which is not unreasonable considering the limitations of humidity measurements devices used for high flow rate and humidity levels. Due to instrumentation and test stand limitations,

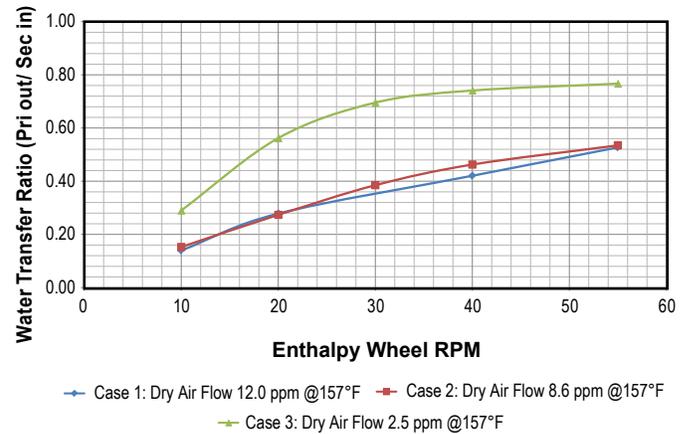

FIGURE 1. Enthalpy Wheel Water Transfer Rate vs. Rotational Speed

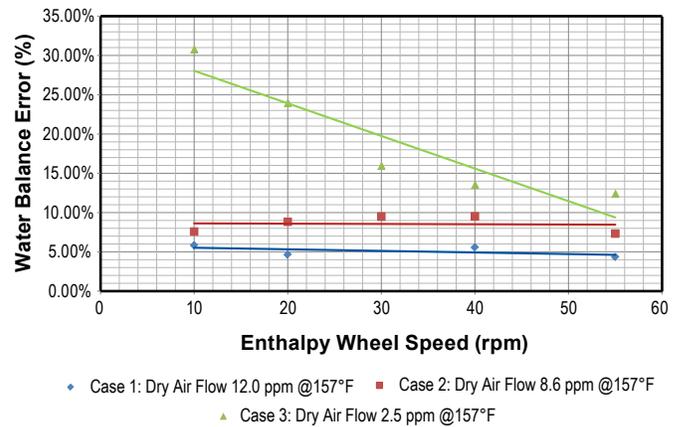

FIGURE 2. Enthalpy Wheel Water Balance Errors vs. Rotational Speed

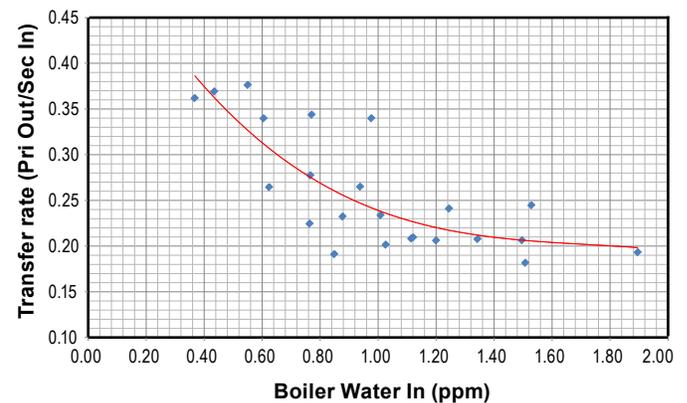

FIGURE 3. Planar Membrane Module Water Transfer Rate vs. Total Water in

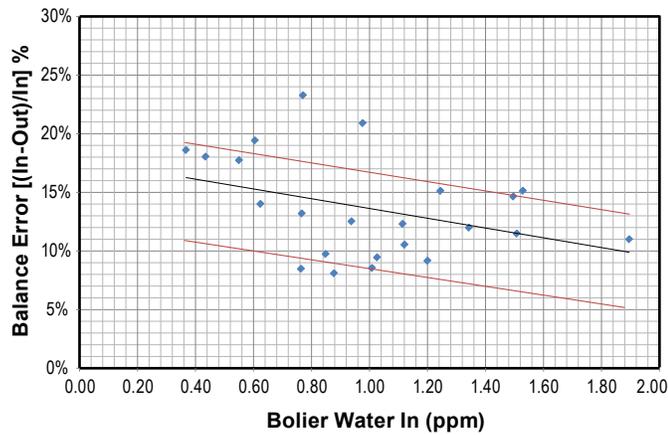

FIGURE 4. Planar Membrane Module Water Balance vs. Total Water in

the humidity of the humidifier inlet stream was limited to about 80 percent. The data scatter cannot be explained; each test point was taken when the system reached the steady-state condition.

Conclusions and Future Directions

All three different types of humidification systems were successfully tested. The enthalpy wheel showed the best water transfer efficiency out of three different types of humidification system tested. The system has a motor for rotation of the wheel and requires seals to isolate the two flow streams.

The last remaining task for this 9-year project is to test a select humidification system for 5,000 cycles reliability testing. Each cycle will consist of step changing the inlet humidity from high to low level and back to high level. The test stand has been modified and the testing has started.

Contract Number: EE00004532

Subcontractors:

- University of Tennessee, Knoxville, TN
- Protonex Inc., Southborough, MA

Project Start Date: October 1, 2010

Project End Date: September 30, 2013

(A) Durability

(B) Cost

Technical Targets

Dynalene's fuel cell coolant (Dynalene FC) is expected to help the fuel cell industry achieve their durability and cost targets to some degree. First of all, the coolant itself is being designed to have a life of 5,000 hrs. It is also expected to have excellent compatibility with the system materials and inhibit corrosion in the coolant loop. This will help in extending the durability of the fuel cell system components such as the pump, the radiator, valves, seals/gaskets and any other components coming in contact with the coolant. The coolant is also designed to work at -40°C, which will assist both transportation and stationary fuel cells to quickly warm up during cold starts.

The cost target for the coolant (in plant-scale production) is about \$10/gallon, which is very close to the retail price of current automotive coolants. This coolant will also eliminate the de-ionizing filter and other hardware associated with it (i.e. fittings, valves). It is also being designed to work with cheaper, lighter and thermally efficient components such as aluminum radiators (instead of stainless steel) and brass heat exchangers.

Fiscal Year (FY) 2011 Objectives

The overall objective of this Phase III Small Business Innovation Research project is to demonstrate the 5,000 hr durability of the nanoparticle-based coolant fluid developed in Phase I and II, and perform further research into how durability is affected and how to improve it. The specific objectives are:

- Validate 5,000 hr durability of the coolant fluid by developing long-term test plans in-house as well as in subcontractor locations.
- Study the effect of nanoparticle properties on its durability under severe conditions such as thermal cycling, high electric field and presence of contaminants.
- Determine the efficiency of corrosion inhibitors in long-term tests under severe conditions.
- Increase the nanoparticle surface charge to >500 $\mu\text{eq/g}$ for both cationic and anionic particles.
- Perform testing of the coolant samples by fuel cell companies and begin commercialization.

Technical Barriers

This project addresses the following technical barriers from the Fuel Cells section (3.4.4) of the Fuel Cell Technologies Program Multi-Year Research, Development and Demonstration Plan:

FY 2011 Accomplishments

This project was originally awarded on a conditional basis until all the financial audits by the DOE were complete. The project started to gain momentum when the final contract was signed in March 2011. The following are the accomplishments:

- Design of the fuel cell system to test Dynalene coolant at the University of Tennessee (UT) facility is complete and parts are ordered.
- Dynalene completed negotiations with Protonex who is building a fuel cell system to supply to Dynalene. Protonex also will test the final coolant (after optimization) for >5,000 hours in one of its systems.
- Dynalene has performed preliminary glassware corrosion tests and has demonstrated the effectiveness of inhibitors towards aluminum and brass.

Introduction

This project addresses the goals of the Fuel Cell Technologies Program of the DOE to have a better

thermal management system for fuel cells. Proper thermal management is crucial to the reliable and safe operation of fuel cells. A coolant with excellent thermo-physical properties, non-toxicity, and low electrical conductivity is desired for this application.

An ideal coolant must be durable for >5,000 hr of operation, and therefore, the coolant must be tested for such duration. Electrical conductivity of the coolant should be less than 10 $\mu\text{S}/\text{cm}$ throughout the testing period and the coolant must be compatible with all the materials (metals, plastics, rubbers and composites) at the highest operating temperature. Current automotive coolants do not satisfy the electrical conductivity criteria due to the presence of ionic corrosion inhibitors in them. Water/glycol solutions without inhibitors can have low starting electrical conductivity, but it can increase rapidly due to corrosion of metal components leading to build-up of ions in the coolant. Fuel cell developers are using water or water/glycol mixtures with a de-ionizing filter in the coolant loop. The filter needs to be replaced frequently to maintain the low electrical conductivity of the coolant. This method significantly increases the operating cost and also adds extra weight/volume to the system.

Dynalene Inc. has developed and patented a fuel cell coolant with the help of DOE Small Business Innovation Research Phase I and Phase II funding (Project # DE-FG02-04ER83884). This technology has been patented in the United States, Canada and Europe. The technical feasibility of this coolant was demonstrated in short-term tests using a dynamic re-circulating loop. The nanoparticles used in the coolant were optimized for size and surface charge density.

Approach

In this Phase III project, Dynalene's plan is to validate the durability of the coolant fluid by developing long-term test plans in-house as well as in subcontractor locations. Nanoparticle-based coolant will be subjected to severe conditions such as thermal cycling, high electric field and presence of contaminants. Efficiency of the non-ionic corrosion inhibitors in long-term tests will be evaluated using electrochemical and glassware corrosion tests. Further research will be dedicated to increase the surface charge density of the nanoparticles. Lastly, samples will be sent to fuel cell companies (including subcontractors) for long-term testing and Dynalene's business development team will start the commercialization effort.

Results

A representative fuel cell coolant and heat rejection system was designed by UT

researchers to accurately simulate the environmental, material, and operational conditions experienced in full-sized fuel cell systems. The ultimate goal is to enable Dynalene to more rapidly develop next generation coolants for fuel cell systems and provide potential customers with application specific independent validation of the benefits of the Dynalene coolant product. Additionally, fundamental understanding of the key controlling parameters that result in ionic impurity contamination within typical coolant subsystems will be determined.

The testing facility designed by UT researchers will emulate the conditions of coolant in an operating fuel cell. Figure 1 shows a schematic of the test system as designed along with the chosen components. Since the project contract was only recently made official, the design of the test rig is complete, and parts will be ordered as soon as the final internal paperwork is completed shortly. The experimental test system will include an operating fuel cell with fully functional coolant flow plate designs, coolant pump, and interchangeable lengths of chosen materials that will be in contact with the coolant. Since the fuel cell will not be a full size stack, an appropriate heat load will be applied to the flow entering the fuel cell to simulate fuel cell stack operating temperature. The system is designed so that different material exposures can be easily implemented by changing component piping materials and lengths. A real fuel cell system radiator will be obtained from industrial suppliers, and has been arranged through Dynalene. Species extraction as shown will enable ex situ measurement of the fluid contents and a variety of important diagnostics to be taken to reveal the key controlling parameters in the degradation of coolant performance. Diagnostics will monitor the coolant system pressure drop, electrical

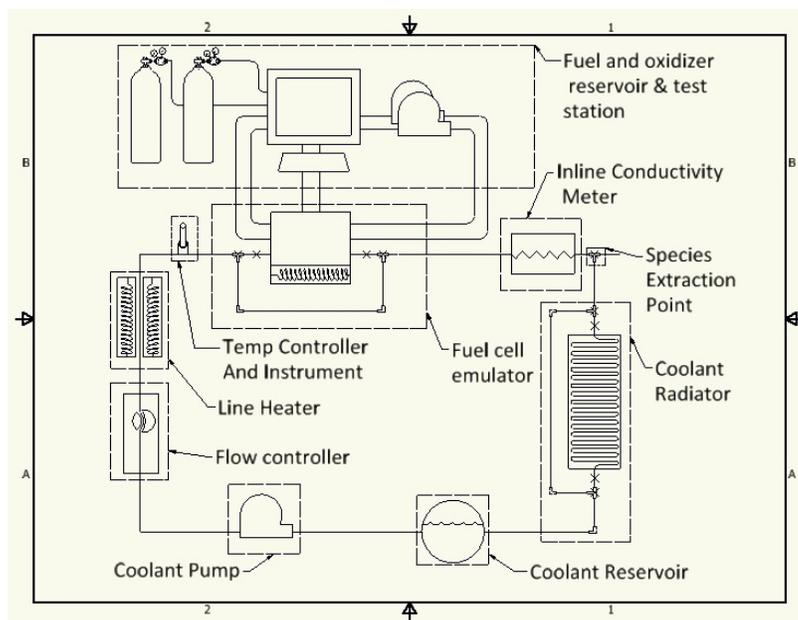

FIGURE 1. Schematic Diagram of the Fuel Cell Coolant Test System at UT

conductivity, flow rate, and heat capacity of the coolant as a function of operating conditions including temperature, coolant flow, and electrical load. A coolant bleed off valve will be installed to allow ex situ evaluation of the type and quantity of contaminants entering the coolant as a function of operating parameters. Both metal and graphite bipolar plate designs with material and coatings purchased from known suppliers and used in operating systems will be integrated into the test system, which will help identify the source of corrosion components. Ex situ surface examination by energy dispersive X-ray spectroscopy, scanning electron microscopy, and other spectroscopic methods will be used to visualize and reveal the composition of local ionic impurities. When complete, this test bed will be validated using different coolant fluids doped with controlled levels of conductive impurities, and the diagnostic systems will be evaluated and calibrated before regular testing.

Dynalene has conducted preliminary corrosion tests using aluminum and brass coupons. These metal coupons were tested in de-ionized water, ethylene glycol/water, propylene glycol/water and Dynalene's fuel cell coolant, Dynalene FC. The tests were conducted in glass jars at 80°C. Figure 2 shows the pictures of these coupons after 350 hours and 700 hours of exposure to the fluid. When they are compared to the control (untested coupons), it is clearly evident that the Dynalene FC fluid has the least corrosive effect towards the metal coupons. It is due to the presence of the non-ionic corrosion inhibitors.

Protonex Inc. has provided Dynalene with a scope of work on how they will test the coolant samples in their fuel cell system. Protonex also will provide a fuel cell system to Dynalene (to be installed at Dynalene's facility) for several long-term tests including 5,000-hr tests. The details of the project and the costs are already worked out. A photograph of the system is shown in Figure 3.

Conclusions and Future Directions

A fuel cell coolant test system has been designed by the UT team that will study the effect of thermal cycling, electric field and the presence of contaminants. Dynalene is preparing various samples of the coolant and performing corrosion and compatibility testing. Preliminary results showed that the corrosive effect of the coolant towards aluminum and brass is much lower than de-ionized water, propylene glycol/water, and ethylene glycol/water. A fuel cell system is being built by Protonex that will be used at Dynalene's facility for 2,000 and 5,000 hr tests.

UT is in the process of ordering all the parts for its test system. Assembly of the system should take place in the next few weeks and should be finished in August. Dynalene will supply three different variations of the coolant for testing. Dynalene will also continue the corrosion and compatibility testing with different system materials. At the same time, samples will be sent to fuel cell developers for

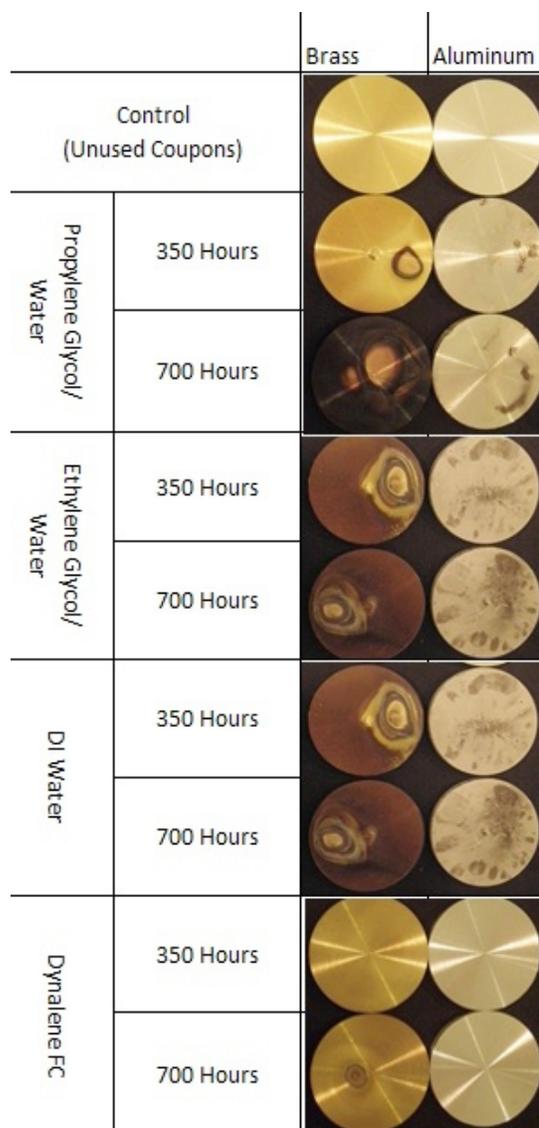

FIGURE 2. Aluminum and Brass Corrosion Testing in Various Coolant Fluids

FIGURE 3. System Photograph

testing in their systems. Feedback from time to time will help Dynalene researchers to optimize the coolant further.

Cost	\$/kWe	750	729 (estimate on volume)

Fiscal Year (FY) 2011 Objectives

The goal of the project is to develop a low-cost 3-10 kW solid oxide fuel cell (SOFC) power generator capable of meeting multiple market applications. This is accomplished by:

- Improving cell power and stability.
- Cost reduction of cell manufacturing.
- Increase stack and system efficiency.
- Prototype testing to meet system efficiency and stability goals.
- Integration to remote and micro-combined heat and power (mCHP) platforms to allow short and longer term market penetrations.

Technical Barriers

This project addresses the following technical barriers from the Fuel Cells section of the Fuel Cell Technologies Program Multi-Year Research, Development and Demonstration Plan:

- (A) Durability
- (B) Cost
- (C) Performance

Technical Targets

This project is directed toward achieving the stationary generation goals of the DOE fuel cell power systems (Table 1). This project will work on cost reduction of the

FY 2011 Accomplishments

- Improved electrical efficiency of stationary units from 35% to 40%.
- Improved durability to over 7,000 hrs demonstrated to over 12,000 hrs demonstrated.
- Increased operating current density and power per cell by 67% while maintaining performance stability.
- Developed a cell manufacturing process capable of cutting high temperature firing times in half with improved yield and cell cost.

Introduction

Achieving combined heat and power goals of over 40% net electrical efficiency and over 85% total energy efficiency are goals of the DOE and present administration to reduce our dependence on foreign energy and reduce the emission of greenhouse gases. SOFCs, with their ability to use the present U.S. fuel infrastructure and high grade waste heat are ideal candidates for this challenge. To date, the limitation on making this goal a reality has been the reliability and cost of such systems.

This project is designed to address these limitations and bring this promising technology to the market place. This is being achieved by working on all aspects of the SOFC power generator including: (1) improving cell power and stability, (2) cost reducing cell manufacture, (3) increasing stack and system efficiency, (4) prototype system testing, (5) and integration into a mCHP platform. This phase of the project

will make a major drive toward the DOE's goals set forth for 2012 stationary power generators.

Approach

To achieve the project objectives, the approach has been to perfect the individual system pieces followed by optimizing their integration through:

- **Cell Technology:** Improving power and stability of the cell building block.
- **Cell Manufacturing:** Improving processing yield and productivity while decreasing material consumption.
- **Stack Technology:** Refining stack assembly and improve heat removal and integrity while cost reducing individual component costs.
- **System Performance:** Developing simplified controls and balance-of-plant components to allow for a reliable, highly efficient unit.

Results

In the past years review, substantial power per tube as well as the significant reduction in operating temperature were demonstrated. It was then stated that the focus of 2010 would then need to revolve around assuring that these increased power per tube figures did not result in any deleterious effects on life expectancy and that they did not interfere with the overall continual goal of cost reduction. Likewise, it was stated that the increased cell power would be further utilized with a number of new generator designs and reforming technology to result in increased overall efficiency meeting the DOE's multi-year goals. All of these goals were met in the research performed under this project in 2010.

Figure 1 shows through testing for nearly 4,000 hrs that an increase in cell current density and cell power did not result in an increased rate of performance decay. The figures shows that for approximately 500 hrs of the initial test the current density was held at 150 mA/cm² and was subsequently increased to 400 mA/cm² for an additional 3,000 hrs. Over this initial period at the pre-2010 operating conditions the voltage decay was limited to -18 mV/1,000 hrs. When the current density was increased, the two cells tested resulted in a decay of -14 and -19 mV/1,000 hrs which is statistically the same under both operating conditions.

Longer term data was also collected to demonstrate the ability to meet DOE's multi-year goal of 40,000 hr stack life. Figure 2 shows the data for one field unit operational for nearly 1.5 yrs. This unit is a full system located outside operating on residential line natural gas including any necessary clean-up and sulfur removal. In previous year reporting it was shown to have 4,500 hrs of operation and Figure 2 shows the stability for 10,000 hrs. This unit is presently at just over 12,000 hrs and continues to operate stably demonstrating over 25% achievement of the DOE goal. This unit will continue to operate and be monitored for stability.

In additions to gains in cell power enhancements were made into reforming technology and generator design to yield efficiency improvements. Figure 3 demonstrates both the power and efficiency gains resulting from these improvements. A fuel cell stack of the pre-2010 vintage was operated under its standard conditions resulting in ~500 W power output at 35-35% electrical efficiency (power/lower heating value of natural gas). The improved cell technology integrated with improved reforming technology resulted in slightly over 1,000 W power output at 42-43% efficiency.

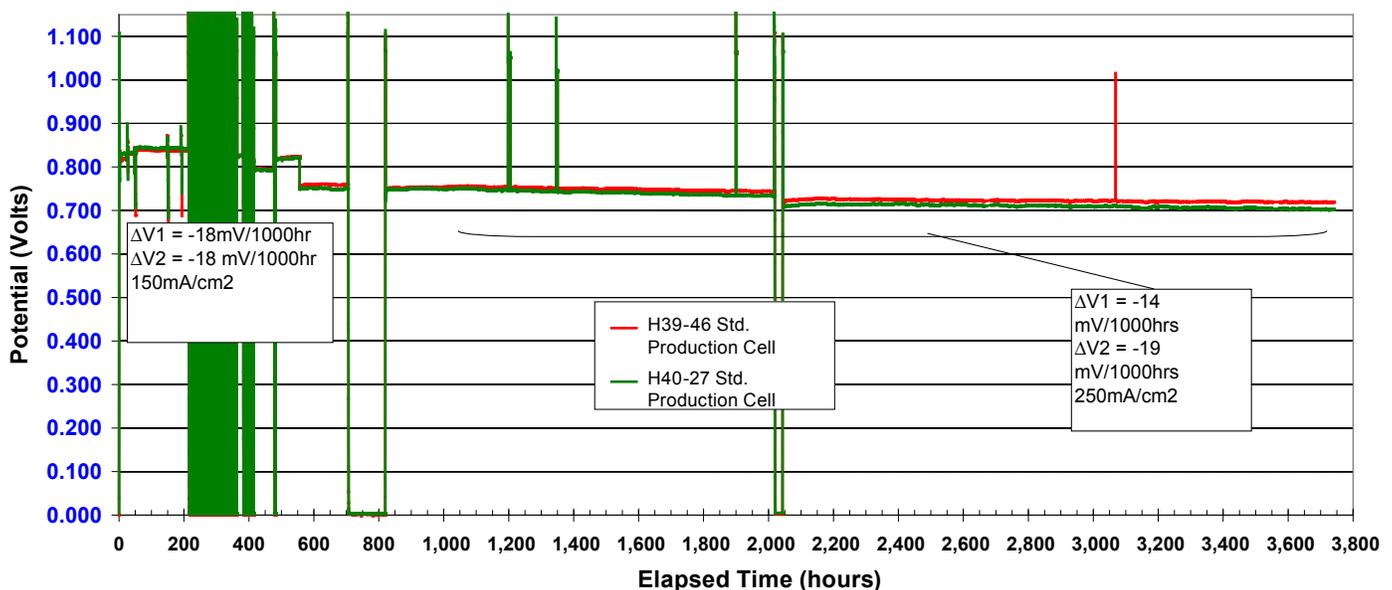

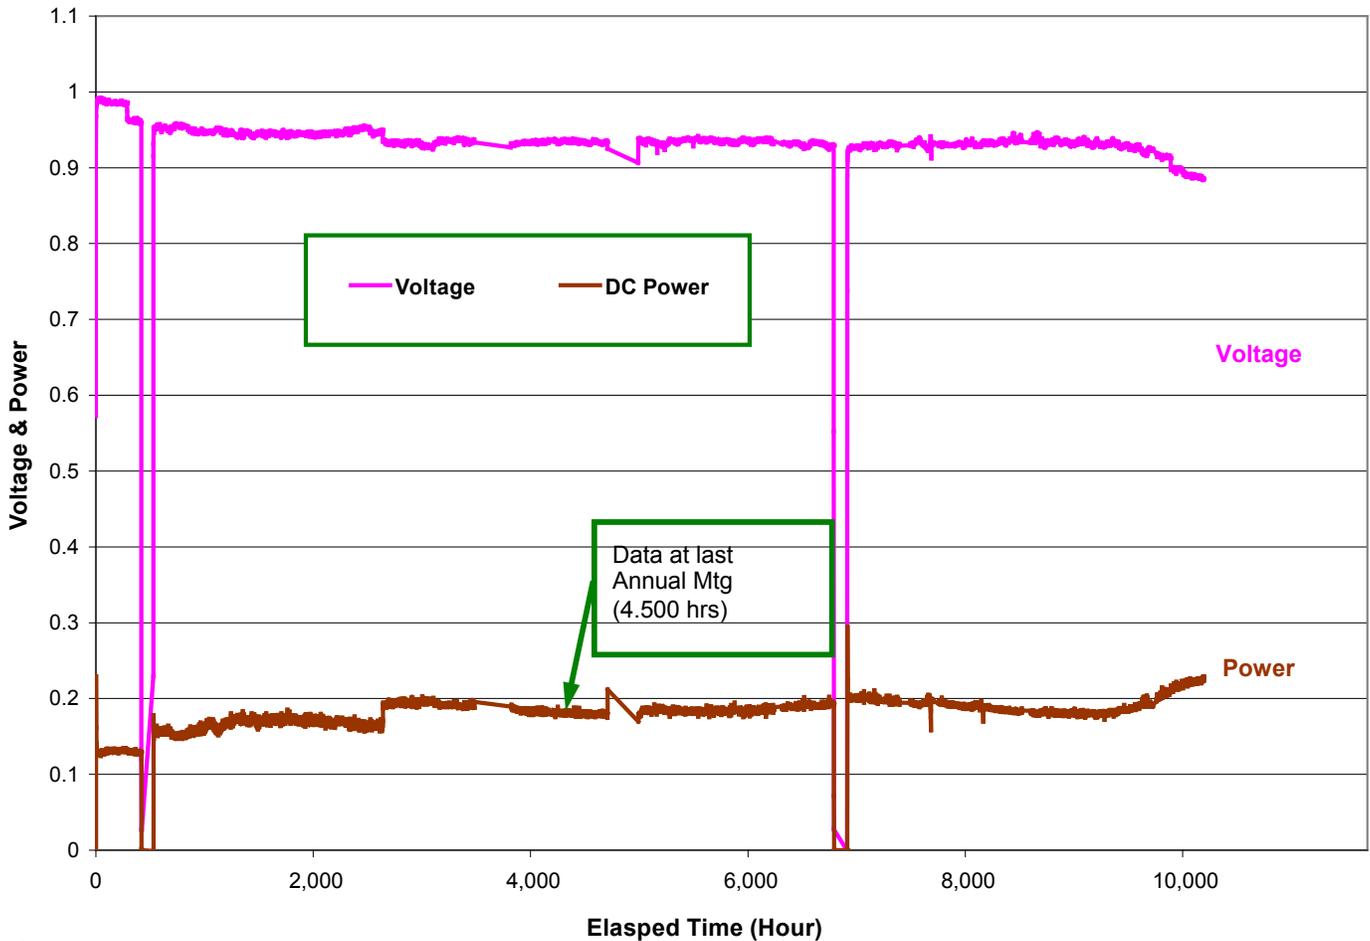

FIGURE 1. Cell Stability at Increased Power per Cell

DC - direct current

FIGURE 2. Long-Term Durability Testing

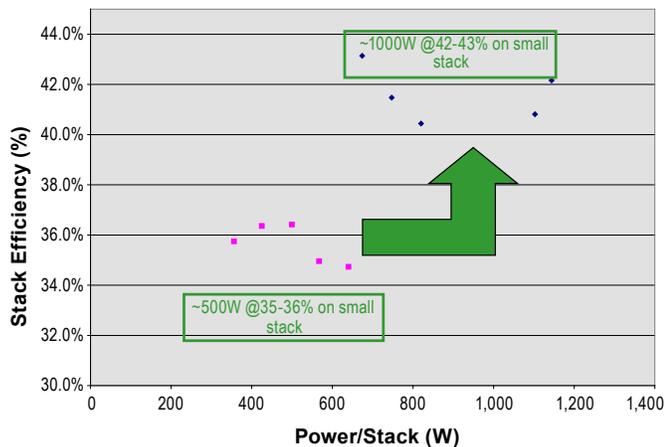

FIGURE 3. Power and Efficiency Enhancements

This doubling of power and seven efficiency point gains result in a lower cost unit since less cells are required for a

given power output and allows Acumentrics' units to achieve over 40% efficiency meeting DOE's long-term goals.

In addition to cell power and stability enhancements, there have been a number of improvements in cost reduction. The fuel cell tube remains the major component to cost and the focus of significant cost reduction activities. Present technology has required that the anode be pre-sintered or "bisque" fired followed by an electrolyte application and subsequent high temperature firing. During the past year research focused on combining these two steps to allow for a co-sintering of the layers. This advancement results in significant cost reduction and productivity enhancements through reduction in capital required. Figure 4 shows the firing sequence of the two step process in addition to the single-step process. The original two-step process required over 85 hours of kiln firing while the single step reduces that to less than 50 hrs. This not only saves on capital equipment but saves on labor cost considering the removal of an unload and re-load step. Reducing handling also reduces loss from breakage further increasing yield and reducing cost. This process is presently being implemented into production.

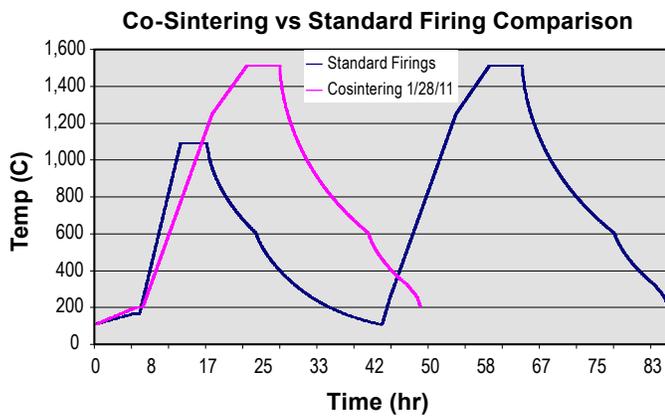

FIGURE 4. Electrolyte Co-Sintering Kiln Firing Cycles

Conclusions and Future Directions

Significant strides have been made in achieving the goals set forth for stationary fuel cell generators under the DOE multi-year plan:

- Improved electrical efficiency of stationary units from 35% to 40%.

- Improved durability to over 12,000 hrs demonstrated.
- Increased operating current density and power per cell by 67% while maintaining performance stability.
- Developed a cell manufacturing process capable of cutting high temperature firing times in half with improved yield and cell cost.

Moving forward, further testing to achieve all of the DOE multi-year goals will be performed as well as cost reduction of the cell and all major sub-systems. Work will continue on market introduction of the technology into remote markets for short term introduction as well as mCHP for longer term market penetration.

Contract Number: DE-FG36-07GO17013

Project Start Date: July 28, 2007
Project End Date: June 30, 2012

Technical Targets

Work under the project is aimed at developing novel fuel processing, polymer electrolyte membrane (PEM) fuel cell technologies and integration strategies in order to make progress toward achieving DOE targets for stationary PEM fuel cell power systems for year 2011. These targets and project progress are shown in Table 1.

TABLE 1. DOE Targets vs. Project Achievements

Metric	2010 Project Status	2011 Project Achievement	2011 DOE Target ¹
Electrical efficiency at rated power	32.6%-prototype	To be determined-demonstration unit testing underway	40%
CHP energy efficiency	60.8%-prototype	To be determined -demonstration unit testing underway	80%
Operating lifetime	832 hours on hydrogen generator	3,425 hours on hydrogen generator ²	40,000 hours

¹Complete DOE Table 3.4.4 found at http://www1.eere.energy.gov/hydrogenandfuelcells/mypp/pdfs/fuel_cells.pdf

²Accumulated on prototype, new retrofit hydrogen generator integrated into demonstration CHP unit now under test through February 2012.

Fiscal Year (FY) 2011 Objectives

- To identify core technology improvements, methodologies and engineered solutions to overcome challenges facing the development of fuel cells (FCs) for use in combined heat and power (CHP) applications.
- To design an integrated system based on the most promising down-selected fuel cell and fuel processor building blocks.
- To build and test a prototype unit in a laboratory setting and collect 300 hours of operating data.
- To optimize, redesign and retrofit a pressure swing adsorption (PSA) unit using lessons learned from prototype to develop a field demonstrator.
- Conduct a six month demonstration in an International Partnership for the Hydrogen Economy country.

Technical Barriers

This project addresses the following technical barriers from the Fuel Cells section of the Fuel Cell Technologies Program Multi-Year Research, Development and Demonstration Plan:

- (A) Durability
- (B) Cost
- (C) Performance

Other challenges being addressed under the project are:

- Reduced startup time by improved thermal management design.
- Reduced size by improved subassembly integration and packaging.

FY 2011 Accomplishments

- Conformité Européenne (“European Conformity”) compliant design of demonstration unit resulting in:
 - 30% size reduction.
 - Grid tie enabled using commercial solar photovoltaic inverter.
 - Integrated feed gas compressor, water system and gas quality monitoring.
 - On-board safety and emissions management.
 - System health monitor with remote data acquisition and analysis for predictive maintenance.
 - Twin stack fuel cell system developed for CHP application to improve system efficiency.
 - Modeled combined heat and power efficiency increased to 78%.¹

¹Expected performance based on model of updated system developed during retrofit redesign and new optimization approach: actual validation testing planned for Q4 FY 2011 - Q2 FY 2012 thus is noted as to be determined in Table 1.

- Modeled natural gas-to-electrical efficiency of 37%.²
- Construction of field demonstration unit.
- Prove-out of the feasibility of adsorption enhanced reforming (AER) as a potential lower cost fuel processor option (eliminates expensive alloys and PSA required by steam methane reformer [SMR] technology).

Table 2 shows run-time hours of the prototype between those reported last year versus additional time logged since then (for FY 2011). The mode of particular importance is that for pure hydrogen production; the increase in hours logged by more than 70% without loss of mechanical integrity and/or notable deterioration in fuel conversion is indicative of a fundamentally sound reformer design.

TABLE 2. Accumulated Hours on Prototype

Mode	Hours-FY 2010	Hours-FY 2011
Hot-Idle ¹	2,164	3,425
Pure Hydrogen Production	832	1432
Power Production	396	733

¹ Reformer combustor hot (700°C) only without synthesis gas or power production occurring.

Introduction

The development of highly efficient and cost-effective clean energy solutions is not without challenge. Hydrogen fuel cell technologies are expected to become a significant player in reducing our dependence on imported fossil fuels and curb the further accumulation of greenhouse gases and criteria pollutants.

This project is focused on the design, fabrication and field demonstration of a stationary CHP system that will provide multi-dwelling residential and light commercial end-users with on-site generated electrical and heating needs. The proposed technology addresses DOE targets by using PEM fuel cell stacks as they have been proven to achieve high efficiency, greater durability and lower costs than competing fuel cell technologies.

Approach

The approach to achieving this project's 40% electrical efficiency target is incremental and based on (1) optimization of the SMR+FC architecture and (2) the development of an 80% or greater thermally efficient AER hydrogen generator that can "plug-and-play" into the same SMR+FC hydrogen feed interface. The SMR+FC optimization relies on allowing slightly less than 100% hydrogen to enter the FC (99% H₂, balance methane

² See footnote 1: prototype achieved 32.6% electrical efficiency-increase to 37% predicted by model of updated system.

[inert to the FC]) which has a negligible impact on the FC performance, but allows for increased hydrogen recovery from the processor whereby its thermal efficiency can be boosted from 70% up to as much as 73%. Process simulations indicate that this method when combined with the benefits of a twin-stack FC configuration can increase the overall CHP system electrical efficiency from its current status of 32.6% (achieved on prototype last year) to approximately 37% (demonstration unit now under test).

An AER hydrogen generator produces a feed stream similar to what the optimized SMR+FC system would receive but operates at 500°C versus 900°C. This means less external energy is needed for AER making it more thermally efficient than SMR. Predictive models developed for us by Sandia National Laboratories during Year 1 of the project indicate that an efficiency of up to 85% can be achieved with the AER compared to only 70%-73% which is the maximum one can obtain with SMR. The product of the AER hydrogen generator and the fuel cell efficiencies, less 12% (assumed value) for the parasitic power requirements to run the CHP system ($[0.85 \times 0.55] - 0.12$), would result in a total system electrical efficiency of approximately 41%. Furthermore, with AER, carbon dioxide removal and reforming occur simultaneously thereby eliminating the need to have an additional purification step (such as a PSA) ultimately leading to lower cost and smaller system. Our work on AER culminated in Year 2 as further development and funding is required to mature the technology to the point of a "plug-and-play" swap of SMR.

At the beginning of this last year of the project, a twin-stack FC configuration was chosen for integration into the CHP demonstrator. Since each of the two stacks can run at a lower output and be combined to produce 10 kW, the efficiency of each stack will be at its maximum point thereby synergistically operating together to achieve an improvement of efficiency from 53% (single stack) to 59%. The result of using two stacks together in terms of total performance can be seen in Figure 1 of the Results section.

Results

Over the course of FY 2011, our project team focused on (1) twin-stack fuel cell system development and testing, (2) stack testing to evaluate the effect on efficiency when feeding 99% hydrogen (balance methane) vs. 100% hydrogen, and (3) a retrofit design and repackaging to accommodate a shorter PSA for the purpose of optimization through relaxing the hydrogen purity requirement all while achieving a system size reduction.

As was determined experimentally (Figure 1) at the 10 kW nominal load to which the CHP system has been designed, a twin-stack configuration performs notably better than a single stack when considered as a total system. The efficiency of a single stack reaches its maximum at approximately 5 kW, while having twin stacks it is possible to run each at this mid-range load and achieve a combined efficiency of 59% vs. 53%.

According to our latest model that forms the design basis of the retrofitted demonstrator, this approach alone adds 1%-2% to the overall CHP system electrical efficiency. Thermal management of the reformer and the reduction of parasitic power demands from the balance of plant also contribute to improving efficiency over the prototype developed in FY 2009-10.

In conclusion, using a twin-stack configuration can increase system efficiency up to 59%:

- The higher voltage output of two stacks enables grid-tie via a commercially available photovoltaic inverters without a boost converter.
- May extend life and ultimately decrease costs as each stack operates at a lower nominal load.
- Air blower output is shared across stacks thus reducing its back pressure and parasitic power draw.

To better understand the potential impact on efficiency running our PEM stacks with less than 100% pure hydrogen in support of our SMR+FC optimization approach, our Research and Technology Group made rig modifications required to run mixes of hydrogen (99%) and methane (1%). Tests were run on a 20-cell evaporatively cooled stack with hydrogen to air stoichiometry of 2:1.

Stack testing was performed over 15 hours during which period our team determined that the mean cell voltage was not adversely impacted by using the mix. Figure 2 depicts a baseline and overlay of cell voltages for pure hydrogen and the mix, respectively.

The work also confirmed that operating the FC with the mix requires more frequent anode purging than when using pure hydrogen in order to maintain the same cell voltage: at 100 A the purge frequency would need to be increased to 5 seconds compared to 6.4 seconds. It should be noted that this hydrogen does not necessarily have to be lost because when the FC is integrated into a CHP unit, the stream is blended into the same fuel that goes to the reformer. As the demonstration unit now under test has been designed to Conformité Européenne directives whereby it must comply

with strict combustible emissions limits, it does indeed recycle this hydrogen.

In parallel to developing the twin-stack fuel cell system and conducting bench tests with 99% hydrogen, our mechanical and process design teams spent a great part

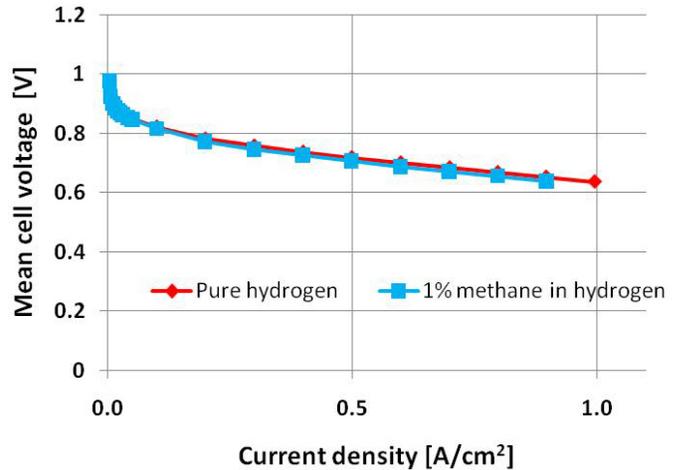

FIGURE 2. Mean Cell Voltage with 99% H₂ Feed vs. 100% H₂ Feed

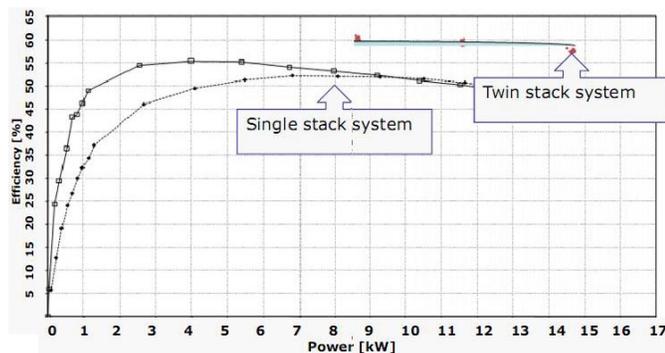

FIGURE 1. Twin-Stack System Efficiency vs. Single Stack Configuration

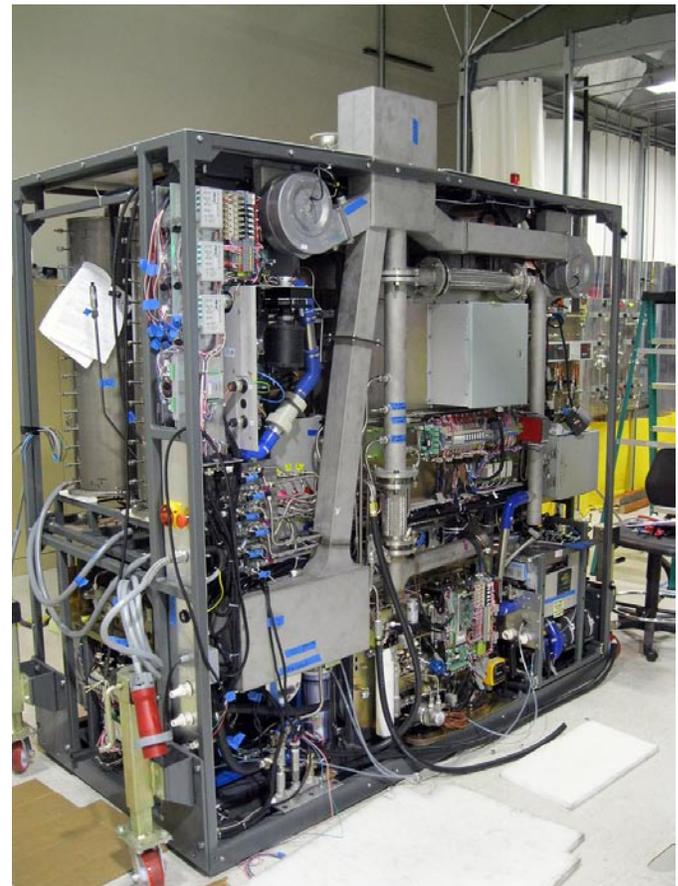

FIGURE 3. Retrofit Demonstration Unit

FIGURE 4. Packaged Demonstration Unit

of this last year evolving the CHP system “from project to product.” The demonstration unit shown in Figure 3 and Figure 4, was subjected to IE’s normal four stage-gated design review process which facilitated being able to reduce the number of subsystems from 23 (on prototype) down to just nine. Key component suppliers were also engaged early on to provide a purpose built PSA that is 1.5’ shorter than the previous generation, and a natural gas compressor suitable for integration within the main frame by being less than one third in size compared to its equivalent standard model.

The field unit of course must meet all safety and environmental regulations as mandated by the European Union, and as such has been implemented with an emissions monitoring and redundant, hard-wired safety shut down subsystem that constantly watches over the main system controller and software. The unit was also designed for ease of installation requiring that the site connections comprise nothing more than city water and gas, drain, heating water inlet and outlet, network connection, and flue. Components that will demand periodic maintenance while under field trial are located in areas of the machine that provide quick and easy access (e.g. water filters, sulfur adsorbent, etc.).

FIGURE 5. Greenwatt Way Demonstration Site

While on site, the system will show real-time status and performance data on a local user interface while also being streamed back to IE headquarters. Startup and shutdowns will normally occur based on those commands the unit receives from the site’s own energy management system.

In addition to designing and building the demonstration unit this last year, the planned site received National Environmental Protection Act (NEPA) determination as required by the project and federal law. A six-month field trial will take place 40 miles southwest of London, England at a multi-residential housing development called Greenwatt Way. This site is owned by Scottish and Southern Energy with whom IE has formed a joint venture and will serve to showcase green technologies and provide housing for up to eight families. A conceptual layout of the site can be seen in Figure 5.

Conclusions and Future Directions

- 2010 - Demonstration site receives NEPA determination.
- 2011 - Conformité Européenne compliant field demonstrator designed and built:
 - Approximately 30% smaller than prototype.
 - Projected system electrical efficiency increased to 37%.
 - Added functionality.
- 2011 - Testing of fuel cell stacks with 99% hydrogen showing no adverse impact:
 - Allows for the evaluation of system level trade-off between FCS and H₂ generator to maximize performance.
- 2012 – Six-month field demonstration and project closure:
 - Logan Energy to provide installation and system maintenance support.
 - System health monitor will relay real-time data back to the IE Knowledge Center.
 - Energy store will showcase ground-source heat pump, biomass boiler, photovoltaic and CHP system.

Introduction

Air filters are a critical part of a fuel cell system. They remove harmful contaminants from the oxidant stream before they reach and damage the fuel cell stack. However, filter suppliers routinely characterize air filters according to standard test procedures that are not suitable for fuel cell systems. These test methods evaluate contaminants at ppm levels when ppb levels are more representative; they only test one contaminant at a time when multiple contaminants exist in ambient air; and they do not evaluate the impact of ambient air conditions (temperature and humidity) on air filter performance. These shortcomings make it impossible to extrapolate the results from the standard test conditions to fuel cell test conditions. As a result, IdaTech proposes to evaluate air filters under “real life” conditions.

Approach

- Determine reasonable air contaminant levels.
- Perform ex situ testing of air filters to evaluate breakthrough and filter capacitance at different contaminant levels, gas flow rates, temperatures and relative humidity.
- Utilize statistical design of experiments to plan and analyze experimental data.

Results

The outdoor test shelter (Figure 1) for the test equipment was built. All electrical wiring is complete. All large items (compressor, chiller, etc.) are installed in the test shelter. Construction of the frames and mounts to house the filter housing, mass flow controllers, and sampling valve

Fiscal Year (FY) 2011 Objectives

- Build test stand for evaluation of commercial air filters for off-road applications.
- Evaluate air-filtration technologies for off-road applications.

Technical Barriers

This project addresses the following technical barriers from the Fuel Cells section (3.4.4) of the Fuel Cell Technologies Program Multi-Year Research, Development and Demonstration Plan:

(A) Durability

FY 2011 Accomplishments

- Gathered information on the air contaminants that may have an effect on fuel cell operation.
- Built exterior test facility to house air filtration test stand.

FIGURE 1. Constructed Outdoor Test Shelter at UC Davis

manifold are complete. A National Electrical Manufacturers Association enclosure for the electrical equipment, instrumentation and gas analyzers has been prepared for equipment installation. Air heaters have been assembled and are ready for installation. Conduit has been installed to connect the test shelter to the control room.

Conclusions and Future Directions

- Complete the installation of all test equipment and plumbing in the outdoor shelter.
- Start shaken with estimated completion of August 1 with testing commencing shortly thereafter.

Contract Number: DE-EE0004535

Subcontractor:
 Energy Technology Services, Glastonbury, CT

Project Start Date: October 1, 2010
 Project End Date: September 30, 2013

Fiscal Year (FY) 2011 Objectives

- Establish the requirements and design for an integrated fuel cell and fuel processor that will meet the technical and operational needs for distributed energy production.
- Develop and integrate key system components – including the fuel cell stack, fuel processor, water management, thermal management, burner, air handling, control system and software.
- Demonstrate that component and mechanical design for the proposed energy system proves the technical and commercial potential of the technology for energy production, emissions, and process economics.
- Develop and demonstrate a 5-10 kW power plant with at least 40% efficiency that is located in the Tri-City Research District Innovation Zone Renewable Energy Demonstration Park.

Technical Barriers

This project addresses the following technical barriers from the Fuel Cells section of the Fuel Cell Technologies Program Multi-Year Research, Development and Demonstration Plan:

- (A) Durability
- (B) Cost
- (C) Performance
- (E) System Thermal and Water Management

Technical Targets

InnovaTek’s research plan addresses several DOE technical targets for stationary applications for fuel processors. Progress in meeting DOE’s technical targets is provided in Table 1. DOE has also established technical targets for integrated stationary proton exchange membrane (PEM) fuel cell power systems operating on natural gas or liquefied petroleum gas (LPG) [1]. Although the InnovaTek system includes a solid oxide fuel cell (SOFC) rather than a PEM fuel cell and reforms bio-oil rather than natural gas, our research plan is addressing the same characteristics for energy efficiency and cost, Table 2.

TABLE 1. Progress toward Meeting Technical Targets for Stationary Fuel Processors for Stationary Applications

Characteristic	Units	2011 Target	InnovaTek 2011 Status
Cost	\$/kW _e	220	1,160 ^a
Cold start-up time to rated power @ -20°C ambient	minutes	< 30	< 30
Transient response time (for 10% to 90% power)	minutes	< 1	< 1
Durability ^b	hours	40,000	To be determined
Survivability (min and max ambient temp)	°C	-25 +40	To be determined

^a Includes projected cost advantage of high-volume production (30,000 units per year). Does not include integrated auxiliaries, battery and power regulator for unassisted start.

^b Time between catalyst and major component replacement.

TABLE 2. Progress toward Meeting Technical Targets for Integrated Stationary Fuel Cell Power Systems Operating on Reformate^a

Characteristic	Units	2011 Target ^c	InnovaTek 2011 Status ^d
Electrical Energy Efficiency ^b @ rated power	%	40	40
Cost	\$/kW _e	750	3,500

^a Includes fuel processor, stack, and all ancillaries.

^b Ratio of direct current output energy to the lower heating value (LHV) of the input fuel average value of rated power over life of power plant; theoretical calculation.

^c For a PEM fuel cell system using natural gas or LPG as fuel.

^d For an SOFC system using bio-oil as fuel.

FY 2011 Accomplishments

- A design requirements document was established that specifies system subcomponents that meet required safety, codes and standards for a fuel cell distributed energy system.

- An optimum process configuration was selected for the production of electricity from pyrolysis oil based on the integrated results of four process models developed by InnovaTek – bio-oil reforming model, SOFC model, anode off gas combustor model, and heat exchanger models.
- A complete mass and energy balance was conducted for the integrated system's 26 different process streams. The results indicate that the system has a theoretical total electrical efficiency of about 40%. This result will be confirmed during testing.
- A prototype system design was completed that will reduce costs through improved thermal management, lower materials cost, and reduced catalyst loading.

Introduction

Alternative energy sources must be sought to meet energy demand for our growing economy and to improve energy security while reducing environmental impacts. Power generation from biomass, along with solar energy, wind energy, nuclear energy, geothermal energy, and others will inevitably be the ingredients of our future energy mix [2]. In addition to facilitating the use of a renewable fuel source, cost and durability are among the most significant challenges to achieving clean, reliable, cost-effective fuel cell systems. Therefore this project is focusing on lowering the cost and increasing the durability of a fuel cell distributed renewable energy system, while also assuring that its performance meets or exceeds that of competing technologies. Work was performed to develop proprietary steam reforming technology that will make it possible to use bio-oil with an SOFC. A highly efficient integrated system design with an SOFC was developed that reduces the loss of heat through an effective thermal design and the use of micro-channel heat exchangers. Modeling and simulations were completed to produce designs for prototype components and to analyze process flow for alternative system configurations. Design alternatives were compared and an integrated system design was completed during this period.

Approach

The technological approach utilizes a steam reforming reactor to convert bio-oil derived from bio waste to hydrogen-rich reformat which fuels an integrated SOFC for power generation. The project will evolve through three developmental stages. Meeting targets for system performance, cost, and durability will be emphasized at each stage.

1. Optimization of SOFC and fuel processor integration – is completed using process simulation and analysis to optimize system design and produce a complete mass and energy balance for individual components of the system.

Process flow as well as piping and instrumentation diagrams are prepared to analyze possible system configurations using Mathcad and FEMLAB models to simulate the process flow paths in the system.

2. Design for manufacturing and field operation – requires continued modeling and analysis such as failure mode effects analysis and several iterations of component builds and tests to compare design options. The dimensions, geometries and flow patterns defined from optimization modeling work completed in stage 1 are translated into three-dimensional computer-aided design (CAD) images and drawings.
3. System demonstration and validation for commercial applications – takes place after down-selection of the final design. Several complete systems will be built to meet the required codes and standards for demonstration at a field site to gain performance data necessary to validate the design and operation of the system. Type tests (requirements validation) and routine tests will be performed before and during the demonstration, and system durability will be assessed.

Results

Design Requirements

The functional and safety requirements for a distributed energy application were identified for a 5 kW fuel cell power plant, including hydrogen production capacity, output power and conditioning requirements, parasitic power use, minimum system efficiency, physical size, feed input and requirements, and lifetime. Criteria were determined for:

- Site establishment
- Enclosure and external surfaces
- Power system design requirements
 - Identify all reasonably foreseeable hazards throughout the anticipated equipment lifetime.
 - Estimate the risk of all hazards from a combination of their probability of occurrence and their foreseeable severity.
 - Eliminate or reduce all hazards as far as practical.
 - Use components that are listed or certified by a nationally recognized testing laboratory.
- Marking
- Technical documents

Process Configuration and Modeling

Important system processes were evaluated to determine materials and energy balances, product yields, and equipment size. The steps in process analysis were: 1) mathematical specification of the process, 2) detailed analysis to obtain mathematical models describing the process, and 3) synthesis and presentation of results to

ensure full understanding of the process. In this task, we used process simulation tools to analyze the system configuration and to develop an optimal system design with detailed mass and energy balance. The mass and energy balance information and component simulations were used for the design of the reactor and heat exchangers. For example our microchannel heat exchanger analyses indicate that our proprietary designs meet the criteria for high heat transfer density with low pressure drop (Figure 1). The appropriate management of thermal systems determines the overall system efficiency; therefore, special attention was placed on the thermal and water management in the system, the two most technically challenging aspects of system integration. Mass and energy balance calculations for the system were used to determine system input requirements and to estimate product output and exhaust rate and composition. This information allowed us to calculate a system electrical efficiency of about 40% based on LHV of fuel input.

Prototype System Design

Manufacturability and integrated product development concepts were used to achieve cost and performance targets for a pre-commercial fuel cell energy system. Various design concept alternatives were considered early in the process. The alternatives were evaluated against design for manufacturing objectives to help reduce both capital equipment costs and maintenance cost while increasing lifetime and robustness. CAD/computer-aided engineering was used to aid in cost effectively developing and analyzing design alternatives. Finite element analysis and other design analysis tools were used to assess the ability of the design to meet functional requirements prior to manufacture as well as assess a part's or product's robustness. Solids modeling helped to visualize the individual part; understand part relationships, orientation and clearances during assembly; detect errors and assembly difficulties; and design the integrated system enclosure (Figure 2).

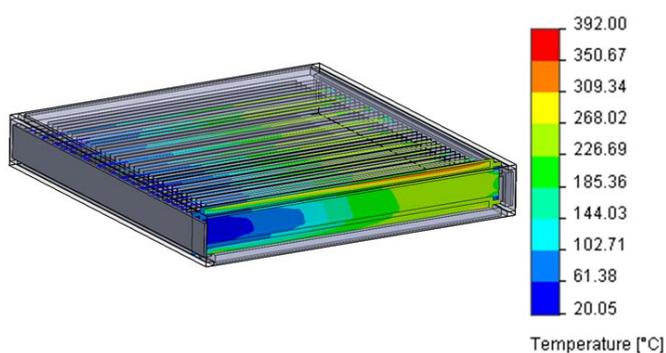

FIGURE 1. Micro channel heat exchanger component simulation — temperature profile through water channel. Results verified that pressure drop across channels meets design criteria; the design results in high heat transfer density; heat transfer meets design criteria.

FIGURE 2. Solid Model of InnovaGen Fuel Cell Distributed Energy 5 kW Power Plant System

Conclusions and Future Directions

- Modeling and analyses indicate that a 5 kW fuel cell distributed energy system that is fueled with renewable, non-food bio-oil is possible through integration of InnovaTek's steam reforming technology and a SOFC.
- On the basis of careful systems modeling and component integration using CAD and thermal systems design with micro-channel heat exchangers, we calculate an overall system electrical efficiency of 40% is possible.
- Prototype construction is underway and testing will verify modeling and simulation results. These results will be used to optimize the design for field-ready systems to be constructed and demonstrated in the City of Richland Renewable Energy Park where they will be tied to the electric utility grid.
- Fabrication and demonstration results will be used to determine whether system cost, performance, and durability targets for a commercially viable system can be met.

*Congressionally directed project

megawatt scale. A current density of 100 mA/cm² at 0.4 V was the initial target for demonstration of a coal-based SOFC.

FY 2011 Accomplishments

FY 2011 research focused on achieving the following milestones:

- Studied the generation of electric power in the coal-based SOFC using two types of solid carbon fuels: biomass-based coconut coke and bituminous Ohio #5 coke.
- Demonstrated that exposure to CO₂ streams increases the performance of Ni-based anode SOFCs during electrochemical oxidation of carbon.
- Synthesized a Cu-Ni/YSZ (yttria-stabilized zirconia) anode catalyst that exhibits higher resistance to deactivation due to SO₂ exposure, as compared to conventional Ni/YSZ anodes.

Introduction

Coal-based SOFCs produce electricity by direct utilization of solid carbon in coal. The use of solid carbon as fuel constitutes a highly desirable technology because of its high energy density (20 kW h/L) compared to methane (0.011 kW h/L), hydrogen (0.003 kW h/L) and diesel (9.8 kW h/L) at standard conditions (i.e., 1 atm and 273 K) [1]. Direct conversion of the chemical energy of carbon to electricity could reduce the complexities associated with fuel processing, facilitating the utilization of abundant carbon resources, and mitigating emission of pollutants (i.e., NO_x species). Coal-based SOFCs with all solid-state components offer significant advantages over molten hydroxide and molten carbonate coal-based fuel cells including (i) ease of stack assembly, and (ii) avoiding electrolyte degradation/corrosion [2]. The performance of the coal-based fuel cell is limited by the extent of contact between the solid carbon and the anode electrode, where the electrochemical oxidation reaction takes place. As a result, development of a highly active coal-based SOFC requires developing anode catalysts that exhibit high activity towards electrochemical oxidation of carbon in coal, and resistance to poisoning due to contaminants such as sulfur. The main objectives of this project are (i) improving the anode catalyst activity and durability, (ii) developing and refining the coal-based SOFC fabrication techniques, and (iii) testing a small-scale coal SOFC system. Successful development of this novel coal fuel cell technology will significantly enhance the energy security of the U.S. and improve the market penetration of fuel cells.

Fiscal Year (FY) 2011 Objectives

Develop a kilowatt-scale coal-based solid oxide fuel cell (SOFC) technology. The outcome of this research effort will form the technological basis for developing a megawatt-scale coal-based SOFC technology. Objectives for 2011 included the following:

- Investigate the effect of the type of solid carbon fuel on the ability to generate electric power in the coal-based SOFC.
- Determine the effect of the concentration of CO₂ on the performance of the coal-based SOFC.
- Develop anode materials that exhibit resistance to deactivation due to exposure to sulfur-containing species.

Technical Barriers

This project addresses the following technical barriers from the Fuel Cells section of the Fuel Cell Technologies Multi-Year Research, Development and Demonstration Plan:

- (A) Durability
- (B) Cost
- (C) Performance

Technical Targets

This project will develop a technological basis for the scale up of power generation capability of a kW SOFC to

Approach

An experimental campaign was designed and implemented to (i) fabricate anode supported SOFCs comprising a Ni/yttria-stabilized zirconia (YSZ) anode, YSZ electrolyte, and YSZ/lanthanum strontium manganese oxide (LSM) cathode, and (ii) evaluate the voltage–current polarization plots (i.e., V-I curves) of the SOFCs at 750°C and 1 atm during testing in H₂, CH₄, CO₂, SO₂, and two types of solid carbon fuel (biomass-based coconut coke and bituminous Ohio #5 coke). Ohio #5 coke was produced by pyrolysis of Ohio #5 coal samples, as described in previous work [3]. The effect of the type of solid carbon fuel was studied by testing the fuel cell in batch mode with 10 g of each fuel, recording the fuel cell steady-state power output at a constant load. The SOFC performance was correlated with the structure and chemical composition of the carbon fuel, which was characterized by diffuse reflectance infrared fourier transformed spectroscopy (DRIFT) and X-ray fluorescence (XRF). The effect of CO₂ streams on the SOFC performance was studied by recording the steady-state V-I polarization plots in H₂ and Ohio #5 coke, and analyzing the composition of gases at the exhaust of the cell. The Ni/YSZ anode electrodes were modified by addition of copper in order to investigate the resistance to deactivation by sulfur poisoning. Cu-Ni/YSZ anode fuel cells were prepared by depositing a layer of copper (Cu⁰) on the surface of reduced Ni/YSZ cells, according to the electroless deposition method. The resistance of the Cu-Ni/YSZ anode to sulfur species was investigated by exposing a Cu-Ni/YSZ fuel cell to a H₂/He and CH₄/He streams containing SO₂ (1.0 vol%), operating the cells at a constant load. The fuel cells used in these studies were characterized by XRF, scanning electron microscopy (SEM), and electrochemical impedance spectroscopy (EIS).

Results

The generation of electric power in the coal-based SOFC was investigated using two types of solid carbon: biomass-based coconut coke and bituminous Ohio #5 coke produced by pyrolysis of Ohio #5 coal. Figure 1 shows direct use of biomass-based coconut coke in the SOFC produced a power density of 125 mW/cm² continuously at 750°C, while the power density with Ohio #5 coke fuel decreased from 50 to 2 mW/cm² after 15 h of testing. The decreased power density was attributed to low activity of Ohio #5 coke, which contains less functional groups and alkali metals as compared to biomass-based coconut coke. Figure 2 shows the DRIFT spectra of Ohio #5 coke and coconut coke, confirming the stronger characteristic infrared (IR) absorptions of saturated (2,927 cm⁻¹) and aromatic C-H bands (3,045 cm⁻¹), aromatic C=C band (1,607 cm⁻¹), and oxygenates present on the surface of coconut coke. The less intensive characteristic IR absorption of Ohio #5 coke was attributed to the removal of surface functional groups during pyrolysis of Ohio #5 coal. Pyrolysis of coal

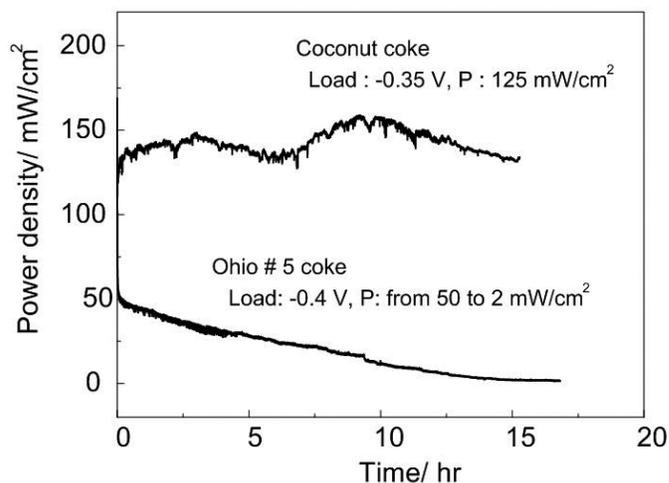

FIGURE 1. Fuel cell power output as a function of time recorded during operation in 10 g of biomass-based coconut coke and bituminous Ohio #5 coke.

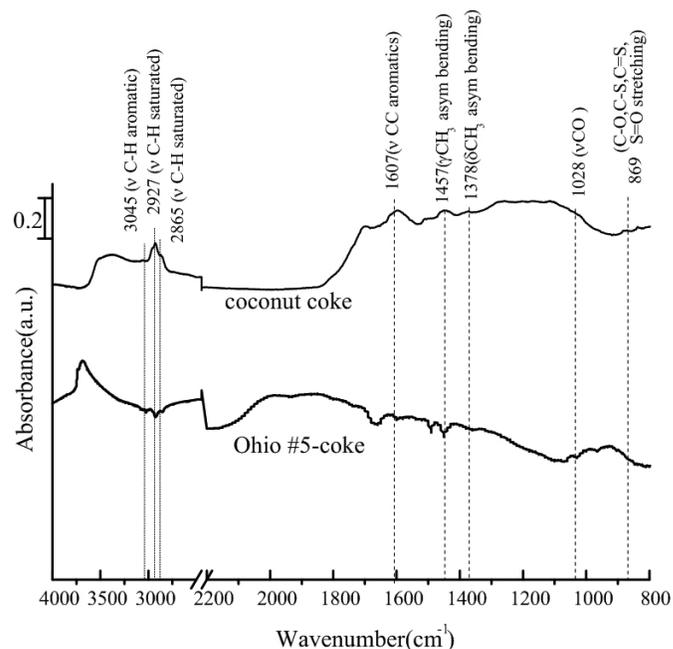

FIGURE 2. DRIFT spectra of Ohio #5 coke and biomass-based coconut coke.

caused the loss of surface functionality and heterogeneity through dehydrogenation, dealkylation, and oxidation reactions. XRF elemental analysis of Ohio #5 coke and coconut coke revealed the higher content of K in coconut coke with respect to Ohio #5 coke. The alkaline metals, e.g. Li, Na, and K, have been reported to catalyze gasification of carbon [4]. Thus, the solid carbon containing alkaline metals would be expected to be more active in gas-phase reactions than the carbon without catalysts. The high fuel cell performance observed during testing in coconut coke suggests that alkaline metals catalyzed the carbon

gasification to produce CO, which can be further undergo electrochemical oxidation by reacting with O^{2-} on the anode surface increasing power density. In contrast, the Ohio #5 coke lacked sufficient gasification activity, resulting in low rate of electrochemical oxidation.

Research studies conducted during FY 2011 provided experimental evidence of the improvement in the performance of Ni-based anode fuel cells in the presence of CO_2 streams. Figure 3 shows the voltage vs. current characteristics of a Ni/YSZ anode supported fuel cell at $750^\circ C$ in 10 g of low-ash carbon and a He/ CO_2 stream containing different concentrations of CO_2 (25-100 vol% CO_2). Increasing the CO_2 concentration from 25 to 75 vol% caused an improvement in the fuel cell performance of nearly 71%, which corresponded to maximum power density of 69 mW/cm^2 . The improvement on the fuel cell performance in the presence of higher CO_2 concentrations could result from electrochemical oxidation of CO produced by gasification reactions of the low-ash carbon and CO_2 (i.e., Boudouard reaction, $C + CO_2 \rightarrow 2CO$). The extent of the low-ash carbon gasification reactions, and their impact on the fuel cell energy efficiency will be further investigated in future studies.

Testing experiments demonstrated that Cu-Ni/YSZ anodes prepared by the electroless deposition of Cu onto Ni/YSZ anodes possess high electrochemical oxidation activity and resistance to deactivation by sulfur containing species. Figure 4 shows a plot of current density as a function of time for a Cu-Ni/YSZ and a Ni/YSZ anode fuel cell exposed to a CH_4/He stream (100 sccm, 50 vol% CH_4) before and after addition of 1 vol% SO_2 . The Cu-Ni/YSZ anode fuel cell produced a current density output of 0.45 A/cm^2 in CH_4/He . Addition of 1 vol% SO_2 resulted in a gradual decrease in the current density output until reaching 0.39 A/cm^2 (13% decay) after 15 min of operation. Further exposure to SO_2 did not cause noticeable changes

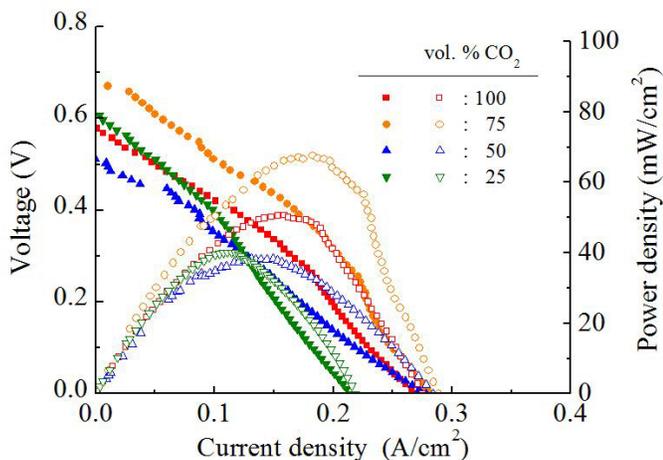

FIGURE 3. Voltage vs. current (closed symbols) and power vs. current (open symbols) characteristics of a Ni anode supported fuel cell at $750^\circ C$ in 10 g of low-ash carbon and a He/ CO_2 .

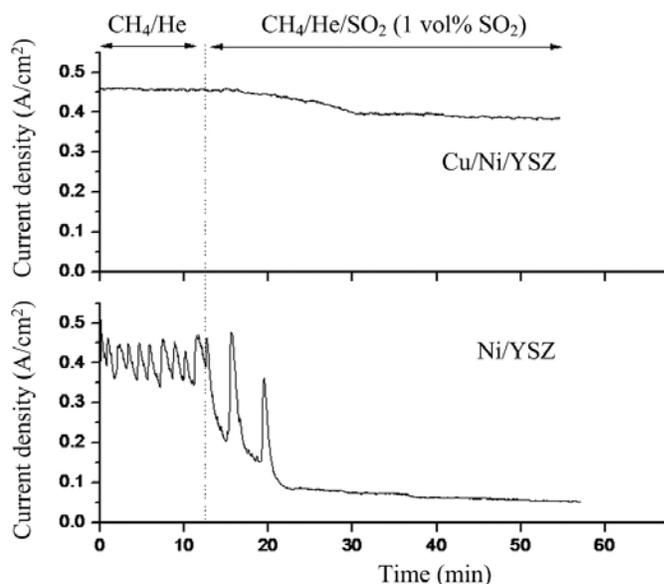

FIGURE 4. Current density as a function of time for a Cu-Ni/YSZ and a Ni/YSZ anode fuel cell exposed to a CH_4/He stream (100 sccm, 50 vol% CH_4) before and after addition of 1 vol% SO_2 .

in current density output, manifesting the resistance of the Cu-Ni/YSZ anode to deactivation by sulfur poisoning. Exposure of the Ni/YSZ anode fuel cell to the CH_4/He stream produced a fluctuating current density output with an average close to 0.4 A/cm^2 . The variation in the current density output could result from rapid formation of carbon deposits on the Ni/YSZ anode (i.e., coking). Addition of 1 vol% SO_2 resulted in a rapid decay in the fuel cell current density output, reaching 0.04 A/cm^2 (90% decay) after 8 min. XRD and XRF analysis of the Ni/YSZ fuel cells after the testing experiments (data not shown) revealed exposure to SO_2 resulted in formation of Ni_3S_2 on the anode surface. Formation of Ni_3S_2 on the Ni/YSZ anode fuel cell could reduce the number of sites available for reaction, resulting in significant losses in the fuel cell current density output. Unlike the Ni/YSZ anode, XRF and XRD spectra of the Cu-Ni/YSZ did not reveal the presence of sulfur-containing species. The absence of sulfur species could result from higher dissociation energy of sulfur species on Cu-Ni surfaces, as described in previous studies [5].

Conclusions and Future Directions

Studies conducted during fiscal year 2011 documented the effects of the chemical composition of solid carbon on the performance of the coal-based SOFC. Addition of CO_2 to Ni-based anode SOFCs was found to increase the gasification of carbon producing CO, which in turn can be electrochemically oxidized increasing the fuel cell power output. Electroless deposition of Cu onto Ni/YSZ anodes was found to improve the fuel cell resistance to sulfur containing species such as SO_2 .

Future studies will focus on:

- Refining the composition, structure, and thickness of the anode catalyst to obtain higher current densities and improved resistance to deactivation.
- Evaluating the long-term anode and cathode catalyst durability.
- Improving a coal injection and fly-ash removal systems for continuous operation for the coal-based SOFC in solid carbon fuels.

*Congressionally directed project

- Utilize synthesized proton-conducting block copolymers to produce films that exhibit nanophase-separated morphologies based on block composition; determine the relationship between proton conductivity and membrane morphology.

Technical Barriers

This project addresses the following technical barriers from the Fuel Cells section of the Fuel Cell Technologies Program Multi-Year Research, Development and Demonstration Plan:

- (B) Cost
- (C) Performance

Technical Targets

- Synthesize bisphenolic comonomers for poly(arylene-ether-sulfone) (PAES) that contain an ion-exchange moiety on a perfluoroalkyl chain tether. Polymerize new comonomers and study membrane conductivity, accelerated degradation, and fuel cell in situ properties. Reproduce known sulfonated poly(arylene-ether-sulfone) (sPAES) benchmark polymers and subject to identical testing. Compare our materials to performance standards established by the DOE.
- Investigate influence of annealing on macromolecular structure, chain dynamics and morphology.
- Knowledge of chemical and mechanical degradation mechanisms and their inter-relationship in membranes.

FY 2011 Accomplishments

- Verified polymer coupling via solution self-assembly (dynamic light scattering, DLS) and have begun to observe nanophase-separated morphologies in polymer films via atomic force microscopy (AFM) and transmission electron microscopy (TEM).
- Explored new coupling chemistries for reactions between perfluorinated polymers and other proton-conducting polymers, utilizing different functionalities to improve coupling efficiency and stability of linkage.

Introduction

The basic theme of the synthetic effort is the synthesis of aromatic hydrocarbon polymers of the poly(arylene ether sulfone) (PSf) or poly(arylene ether ketone) type, containing ion exchange groups tethered to the backbone via perfluorinated alkylene linkages. The implementation

Fiscal Year (FY) 2011 Objectives

Molecular-morphological tailoring and evaluation of novel, low-cost hydrocarbon fuel cell membranes with high-temperature performance and long-term chemical/mechanical durability. This effort supports the Hydrogen Program stated in the Multi-Year Program Plan by developing high-temperature, low relative humidity (RH), high proton conductive membranes for use in polymer electrolyte membrane (PEM) fuel cells – focus is on alternative materials with performance up to 120°C at low RH.

- Synthesis of aromatic hydrocarbon polymers. Organic structure tailoring includes variation of linking moieties between aromatic groups, ion exchange density/distribution, molecular weight and block vs. random copolymers (Storey, Patton, Savin).
- Fundamental information regarding microstructure and physical properties and correlation using advanced characterization tools (Mauritz, Savin).
- Having identified superior materials and optimized membrane electrode assembly (MEA) processing, the nature/mechanisms of coupled chemical and mechanical degradation and morphological alteration investigated during accelerated ex situ degradation and PEM fuel cell testing (Mauritz).
- Mechanical/chemical/thermal stability of the membranes will be increased over a broad temperature-humidity range. MEAs fabricated from synthesized ionomers and tested for fuel cell performance and durability.

of the 1-H-1,2,3-triazole into a PSf is an approach to create a proton exchange membrane that can operate at high temperatures and low humidity. Triazoles are amphiprotic charge carriers, e.g., moieties capable of serving both as proton donors and proton acceptors, so water is no longer necessary as a proton transport medium. Also, the fuel cell can operate at higher temperatures increasing the efficiency of the electrodes.

Traditionally, polymers have been blended for many years to create hybrid properties in a bulk material. Mixing polymers that are chemically/physically incompatible usually results in large, inconsistent phase segregation of each polymer within the bulk material. However, covalent linking of these incompatible polymers to create “diblock copolymers” results in materials with uniform microphase behavior (morphology) and the associated morphologies as a function of block composition ϕ_A and segregation strength χN for bulk coil-coil block copolymers. In our work, our intention was produce block copolymers containing a proton-conducting block and a perfluorinated propylene oxide (PFPO) polymer; the PFPO block is highly incompatible (strongly segregating) with the proton-conducting block leading to well-defined morphologies based on established criteria. By varying the composition of each respective block in the copolymer, we seek to produce a myriad of well-defined morphologies with long-range order (creating proton-conducting channels) and develop a relationship between membrane morphology and proton conductivity. Phase behavior of block copolymers will be mapped vs. block composition using TEM, AFM and small angle X-ray scattering (SAXS). Synthesized materials will be characterized for proton conductivity and mechanical/chemical/thermal stability over broad temperature and RH ranges using a variety of spectroscopic, dielectric, microscopic and viscoelastic methods and evaluated for fuel cell performance.

Approach

In the past year, new structural variations were examined with the aim of providing improved morphological connectivity of ion exchange groups within the bulk membrane material. These approaches included synthesis of hydrophilic/hydrophobic multi-block copolymers, new

ion-containing comonomers with a longer tether length, and new hydrophobic comonomers.

A 1-H-1,2,3-triazole tethered PSf has the potential to eliminate a lot of issues associated with the current PEM material. The 1-H-1,2,3-triazole can be achieved through a copper-catalyzed 1,3-dipolar cycloaddition of an alkyne with azidomethyl pivalate to give the terminal N-protected triazole. Further synthesis can afford a 4-bromophenol functionalized triazole followed by a C-H activation and Suzuki-Miyaura reaction onto the PSf backbone.

For block copolymer synthesis, our interests lie in determining factors that affect bulk morphology, water content, and ion exchange capacity in block copolymers composed of PFPO and a proton-conducting block. We synthesize a variety of polymers with varying composition to map the phase behavior of PFPO-based/proton-conducting block copolymers. Successful synthesis of block copolymers will be confirmed by NMR and DLS. Solutions of the synthesized block copolymers will then be cast and annealed to make films, whereby the films will be characterized in terms of morphology by AFM, TEM, and SAXS. Lastly, we will determine ion exchange capacity and water uptake.

Results

PAES multi-block copolymers were prepared from hydrophilic and hydrophobic prepolymers. Prepolymers were synthesized by reaction of the new ion-containing comonomer, N,N-diisopropylethylammonium 2,2-bis(p-hydroxyphenyl)pentafluoropropanesulfonate (HPPS) (see Figure 1), with bis-(4-fluorophenyl) sulfone (FPS), and biphenol (BP) with FPS, respectively. Prepolymers and multi-block copolymers were prepared at 180°C in N,N-dimethylacetamide in the presence of K_2CO_3 . The prepolymers were reacted overnight; the multi-block copolymers were reacted only 80 min to minimize transesterification. ^{19}F NMR provided molecular weight of hydrophilic prepolymers bearing aryl fluoride end groups. Gel permeation chromatography was used to characterize the multi-block copolymers. Copolymer block lengths were determined by quantifying ^{13}C NMR peak areas of quaternary carbon atoms adjacent to sulfur in FPS moieties. Hydrophilic and hydrophobic block lengths were in the range 9.4-23.4 and 4.4-11.8 repeating units, respectively. AFM

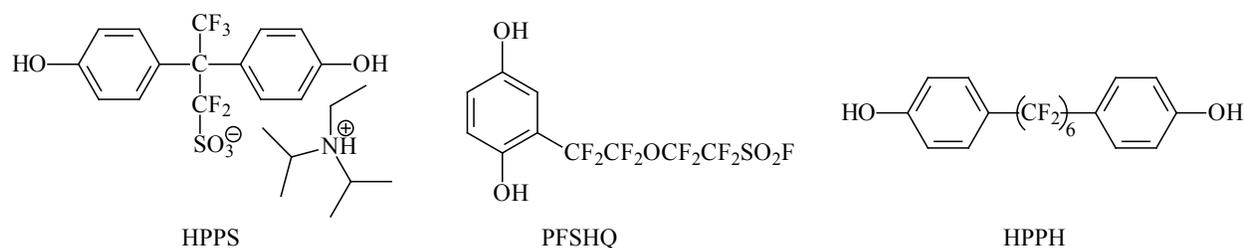

FIGURE 1. Three New Monomers for Ion-Containing PAES

showed phase separation for all block lengths. Conductivity at 80°C and 100% RH ranged from 6.2–34.3 mS/cm, with the best value obtained for hydrophilic/hydrophobic block lengths of 13.3/6.0.

Performance of HPPS-containing PAES were disappointing, and it was hypothesized that the tether element was too short. Thus, a new ion-containing bisphenolic monomer incorporating a longer tether, 2-(5-fluorosulfonyl-3-oxaoctafluoropentyl)-1,4-dihydroxybenzene (PFSHQ) (see Figure 1), was synthesized in two steps from 1,4-dimethoxybenzene and the tether element, 5-iodooctafluoro-3-oxapentanesulfonyl fluoride. Purified yield for the first step was low (12%); purified yield of the second step was 64%. The structure of the monomer (potassium sulfonate form) was proven by NMR and mass spectrometries. Gram quantities of the new monomer were produced, and used in an attempted synthesis of a new poly(arylene ether sulfone) polymer; however, a crosslinked product resulted.

Synthesis of a new hydrophobic monomer, 1,6-di(4-hydroxyl)phenylperfluorohexane (HPPH) (see Figure 1), was accomplished using a copper coupling reaction between 2 eq of 4-iodophenol and 1 eq of 1,6-diiodoperfluorohexane. The yield was 56%, the structure was confirmed by NMR spectroscopy. Copolymerization of HPPH with 3,3'-disulfonate-4,4'-difluorodiphenylsulfone in the presence of K_2CO_3 , however, resulting only in homopolymerization of HPPH to yield an insoluble polymer (assumed to be crosslinked). The failure of both PFSHQ and HPPH in nucleophilic aromatic substitution polymerization is apparently due to attachment of a CF_2 moiety directly to the aromatic ring. In contrast, HPPS polymerizes in a very predictable fashion.

The synthesis of triazole-functionalized polymers followed Figure 2. The rigidity of the PSf backbone limits the mobility of the mobility of the triazoles and decreases its charge transfer capabilities even at a concentration of triazoles of one per repeat unit. The stiffness of the

backbone also limits the ability of the material to undergo phase separation to create channels for the protons to travel through.

Initially, our work establishing efficient coupling strategies of acid chloride-functional PFPO with hydroxyl-functional poly(styrene) was centered around direct coupling of the two blocks. The challenges here were to determine proper solvent/solvent mixtures, reaction temperatures, concentrations, etc., to effectively produce block copolymers. The DLS results confirm (1) successful polystyrene (PS)-b-PFPO (SF) copolymer formation and (2) aggregate size in methanol after sulfonation of the PS blocks thereby forming sulfonated-PS-b-PFPO (sSF) block copolymers. Figure 3 presents an AFM phase image for SF 5-4 (~55 wt% polystyrene). This image suggests cylindrical formation with domain sizes of approximately 10 nm. The aggregate size in tetrahydrofuran illustrates efficient synthesis of SF block copolymers; however, after sulfonation, the aggregate sizes are extremely small. This suggests that scission is possibly occurring between PS and PFPO which seems to be a likely occurrence since the two blocks are connected by an ester linkage (susceptible to hydrolysis).

Further work has persisted on (1) modifying the functionality of PFPO-COOH to facilitate efficient coupling with proton-conducting blocks (i.e. PAES) and (2) attempted coupling reactions of modified PFPO with hydroxyl-terminated PAES to yield stable, robust linkages. PFPO chain end modification was performed by reacting PFPO-COOH with diamino halide compounds to form benzimidazole groups. We attempted nucleophilic aromatic substitution coupling with hydroxyl-terminated PAES. Encouragingly, we were able to make a homogenous solution in hexafluoroisopropanol, and the reaction was allowed to react for 1 day at 120°C. We are currently performing light scattering and NMR experiments to confirm to product of the reaction, and we note that the reaction yielded a product with a color (reddish) different from the two reactants.

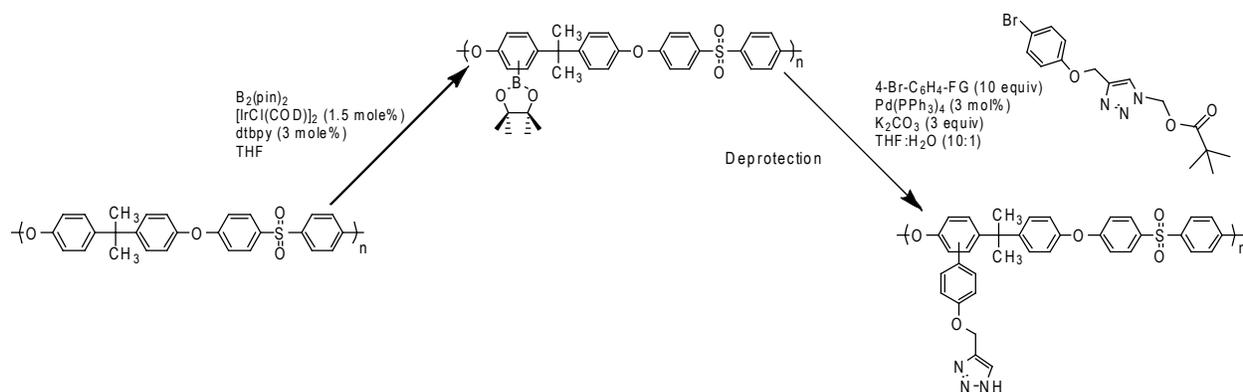

FIGURE 2. Functionalization of Aromatic Rings of Polysulfone through C-H Activation and Suzuki-Miyaura Reaction followed by Deprotection under Basic Conditions

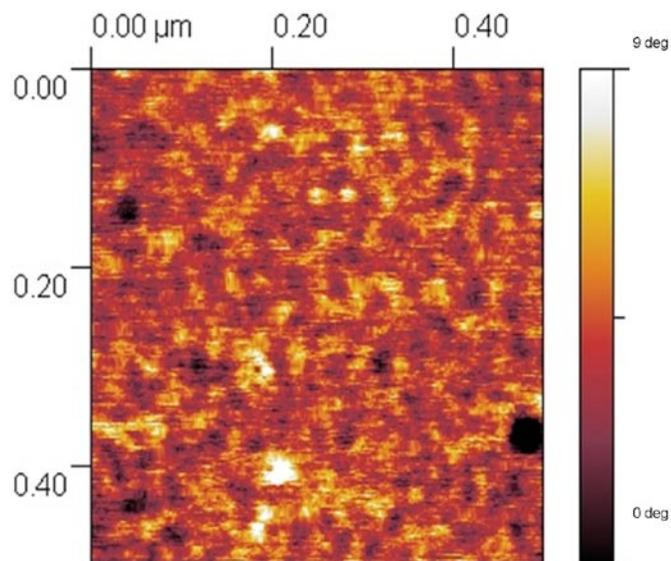

FIGURE 3. AFM Phase Image of a 50 mg/mL PFPO_{4K}-PS_{5K} Spin-Cast from a solution of 80% Trifluorotoluene and 20% Methoxy-nonafluorobutane

Mechanically robust membranes were prepared by blending the triazole-PSf and phosphonic acid PSf. However, preliminary conductivity measurements show the films exhibit low conductivity at 120°C. Triazole-PSf membrane films were also doped with phosphoric acid to improve their conductivity at high temperatures. However, conductivities at 120°C for the films were very low at over the range of RH. The reason for low conductivity is thought to be the -NH groups of the triazole tether is not accessible to H₃PO₄ or phosphonic acid groups. Efforts are now in progress to prepare and test PSf backbone with higher concentrations of tethered triazole (Figure 4).

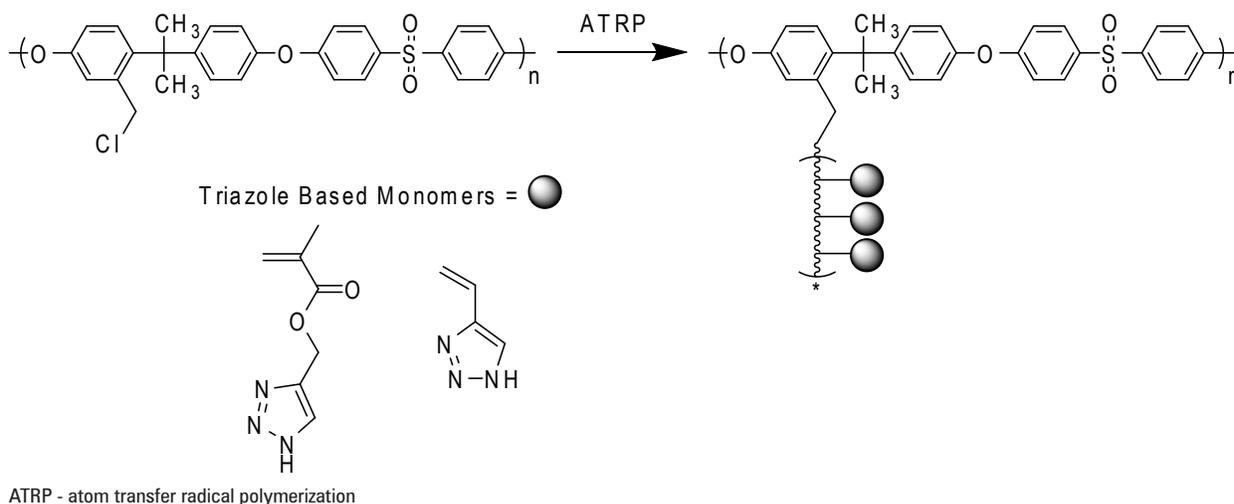

FIGURE 4. Polymerization of Triazole-Based Vinyl Monomers off of a Chloromethylated PSf Backbone via Atom Transfer Radical Polymerization

Conclusions and Future Directions

- The single tethered triazoles are limited due to the rigidity of the PSf backbone.
- A higher concentration of triazoles will allow for better phase separation to occur and can be achieved by growing triazole based monomers from a chloromethylated PSf backbone via atom transfer radical polymerization.
- Produce films of synthesized block copolymers and study the nanophase-separated behavior (due to the coupling producing triblock copolymers, we can exploit the block composition to produce even more morphologies than we see with diblock copolymers).
- Coupling of PFPO-bzimF with hydroxyl-functional PAES that has a higher degree of sulfonation (higher hydrophilicity and introduction of proton conductivity).

Contract Number: DE-FG36-08GO88113

Project Start Date: August 1, 2008

Project End Date: June 30, 2012

*Congressionally directed project

- Determine long-term performance of key components such as catalysts, sorbents, heat exchangers, control valves, reactors, piping, and insulation.
- Evaluate the impact of ambient temperatures (hot and cold environment) on performance and component reliability.
- Determine system response for transient operation.

Technical Barriers

This project addresses the following technical barriers from the Fuel Cells section of the Fuel Cell Technologies Program Multi-Year Research, Development and Demonstration Plan:

- (A) Durability
- (C) Performance
- (G) Start-Up and Shut-Down Time and Energy/Transient Operation

These barriers will be addressed as they relate to the three external fuel processor subsystems.

Fiscal Year (FY) 2011 Objectives

The main goal of this project is to perform extended durability testing of the external fuel processor (EFP) for a one megawatt (MWe) solid oxide fuel cell (SOFC) power plant concept being developed by Rolls-Royce Fuel Cell Systems (US) Inc. (RRFCS). The specific objectives are to:

- Conduct long-term tests in relevant environments for the three EFP subsystems that support operation of a 1-MWe SOFC power plant. The subsystems include:
 - Synthesis-gas subsystem
 - Start-gas subsystem
 - Desulfurizer subsystem

Technical Targets

This project addresses milestone 59 in the Fuel Cells section of the Fuel Cell Technologies Program Multi-Year Research, Development and Demonstration (RD&D) Plan. Milestone 59 is to “evaluate fuel processing subsystem performance for distributed generation against system targets for 2011.” These targets will be addressed as they relate to durability, performance (gas quality) and transient response of the EFP subsystems. Table 1 shows the technical targets for the project.

TABLE 1. Technical Targets

Characteristic	Units	2005 Status	DOE 2011 Targets	RRFCS 2011 Targets
Cold start-up time to full load @ -20°C ambient	minutes	< 90	< 30	60
Transient response (10 to 90% load) Load rate of change	Minutes (% per min)	< 5 (16)	1 (80)	2 (40)
Durability	hours	20,000	40,000	8,000
Survivability (min and max ambient temperature)	°C	-25	-35	-40
	°C	+40	+40	+40
Sulfur content in product stream	ppbv (dry)	< 10	< 4	< 100

FY 2011 Accomplishments

- Prepared samples from the post-test inspection of synthesis gas subsystem for analysis.
- Completed commissioning of the desulfurizer subsystem.
- Completed 4,649 hours of the 8,000-hr desulfurizer subsystem durability test.
- Commissioned mechanical and electrical hardware for the start-gas subsystem.
- Started commissioning of the control system software for the start-gas subsystem.

Introduction

RRFCS is developing a 1-MWe SOFC power plant for stationary power application. An integral part of the SOFC power plant is the EFP. It uses pipeline natural gas and compressed air to generate all the gas streams required by the SOFC power plant for start-up/shut-down (non-flammable reducing gas referred to as start gas), low-load operation (synthesis gas) and normal operation (desulfurized natural gas). Thus it eliminates the need for on-site storage of high-pressure, bottled gases such as nitrogen and hydrogen.

Approach

The approach for this project is to conduct durability tests in relevant environments using full-scale components for the EFP of a 1-MWe SOFC power plant. The components were designed and built as part of another project and made available for the durability testing. An outdoor test facility was constructed as part of a third project so that the EFP could be tested under hot- and cold-weather conditions that would be expected for a 1-MWe SOFC power plant operating in northeast Ohio. Figure 1 shows a photograph of the EFP desulfurizer subsystem under test in February 2011 in the outdoor test facility.

The durability testing includes:

- Synthesis-gas subsystem testing for multiple start-ups and 1,000 hours of operation in a heated, indoor enclosure. This subsystem is used only during low-load operation of the SOFC to balance the thermal input and is required to operate for only a few hundred hours per year. Therefore the 1,000-hour test will simulate a 5-year service life.
- Start-gas subsystem testing for multiple start-ups and 1,000 hours of operation in an outdoor (hot and cold) environment. This subsystem is used only during start-up and shut-down of the SOFC and is required to operate for only a few hundred hours per year. Therefore the 1,000-hour test will simulate a 5-year service life.

FIGURE 1. Desulfurizer Subsystem Being Tested in the Outdoor Test Facility (-23°C)

- Desulfurizer subsystem testing for 8,000 hours in an outdoor (hot and cold) environment. This subsystem operates whenever the SOFC is making power therefore it is expected to operate for much longer periods compared to the other two subsystems. The 8,000-hour test represents the time period between yearly maintenance intervals.

After completing the durability tests, post-test analyses of the hardware will be performed. Subsystem components (catalysts, sorbents, piping, reactors, insulation, valves, heaters, heat exchangers, nitrogen membrane, etc.) will be inspected for deposits, signs of wear, damage, corrosion, and erosion. Physical and chemical analyses will be performed on components as required.

The durability tests will demonstrate that the EFP subsystems are ready for a full-scale SOFC system demonstration.

Results for 2011

Synthesis-Gas Subsystem

The synthesis-gas subsystem was disassembled after completion of the 1,000-hour durability test. The catalyst was removed from the reactor and samples were submitted for chemical and physical analyses. Small samples of the subsystem's metal components were prepared for chemical and physical analyses to quantify metal loss and corrosion. Results from these analyses had not been received by the time of this report.

Desulfurizer Subsystem

The desulfurizer subsystem was the second of the three subsystems to be tested. It generates pressurized, desulfurized natural gas (DNG) from high-pressure pipeline natural gas. The RRFCS target for maximum allowable sulfur level in the DNG is 100 parts per billion (ppb) on a volume basis.

The software packages for the desulfurizer subsystem's control and safety systems were commissioned and verified for automatic operation. This enables unattended operation to support long-term (8,000-hr) durability testing. The desulfurizer subsystem is being operated in the outdoor test facility to determine the impact of ambient temperature on start-up and system operation. The testing also determined the transient response to load changes and subsystem durability.

The desulfurizer subsystem uses a natural gas burner to provide warm gas (300°C) to heat up the sorbent beds for start-up. The heat-up from 20°C required about 12 hours. This time increased to 27 hours when the heat-up was performed at -23°C, the coldest temperature recorded through the winter season at the outdoor test facility in North Canton, Ohio. The heat-up time at the very cold condition was longer than desired. The procedure for desulfurizer subsystem heat-up is being modified to reduce the time required to heat up from very cold conditions.

Once the sorbent was at temperature, it was maintained in a standby state using electric heaters. When in the standby state, gas flows were initiated for start up of the desulfurizer subsystem. Start-ups were performed at ambient temperatures ranging from -23 to 30°C. The start-up time required to begin producing DNG typically ranged from 56 to 74 minutes for these temperatures. These results were considered acceptable by RRFCS.

The transient response for the desulfurizer subsystem was tested over a load change from 10% to 40% of the design DNG flow rate. The upper range used for the load change was limited by the natural gas compressor and not the desulfurizer subsystem. The time required by the desulfurizer subsystem for the load change was 25 seconds. This gives a load rate of change of 72% per minute. This exceeded the RRFCS target of 40% per minute. The plots

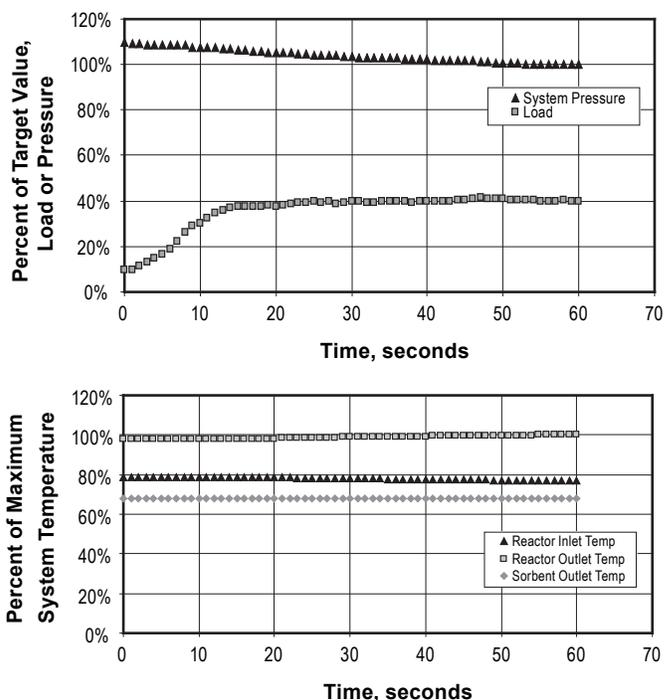

FIGURE 2. Desulfurizer Subsystem's Transient Response to Load Change

in Figure 2 show the load change as a function of time along with the response of the system pressure and temperatures. The pressure declined slightly at the higher load while the temperatures remain fairly constant. All the process variables showed a well controlled response to the rapid change in load.

The desulfurizer subsystem has been operating over the past eight months. It had logged a total of 4,649 hours on stream by the beginning of June 2011. The subsystem has maintained the sulfur level in the DNG to less than 10 ppb (the lower detection limit of the on-line sulfur analyzer) for the vast majority of the durability test period. This was lower than the RRFCS target of 100 ppb. The subsystem has successfully endured four trips due to auxiliary system failures (natural gas compressor, flare stack, and site power) and also has undergone two planned shutdowns to remove test-coupon samples. The plot in Figure 3 shows the sulfur level and the total hydrocarbons in the DNG leaving the desulfurizer subsystem. A small fraction of the hydrocarbons in the natural gas feed are converted into carbon dioxide and water to provide the heat required to support the desulfurization process.

The desulfurizer subsystem continues to operate and is expected to achieve the 8,000-hour durability target by mid-November (2011).

Start-Gas Subsystem

The mechanical and electrical commissioning for the start-gas subsystem has been completed. The operation of

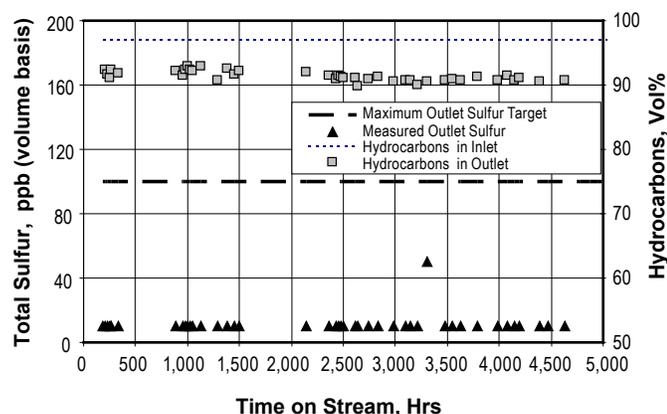

FIGURE 3. Sulfur Level and Total Hydrocarbons in Desulfurized Natural Gas

all control and safety system hardware was verified. Work continues on commissioning the control system software to allow automatic operation. Automatic operation of the start-gas subsystem had not been achieved by the time of this report. However, the subsystem was successfully started and operated at the full load condition in the manual mode of operation.

Conclusions

The desulfurizer subsystem durability testing has logged 4,649 hours of the planned 8,000- hour test. It is working well with test results showing that performance is meeting or exceeding RRFCS requirements:

- Transient response (load rate of change) was 72% per minute.
- Sulfur level was less than 10 ppb.
- Start-up times ranged from 56 minutes to 74 minutes for ambient temperatures ranging from -23 to 30°C.

The start-gas subsystem is ready for final commissioning activities. Once they are completed, durability testing will begin.

Future Directions

2011

- Complete commissioning of control system software for the start-gas subsystem (fourth quarter 2011).
- Complete the 8,000-hour desulfurizer subsystem durability test (fourth quarter 2011).

2012

- Begin durability testing of start-subsystem (first quarter 2012).
- Reduce heat-up time at cold conditions for desulfurizer subsystem (first quarter 2012).
- Complete durability testing of start-gas subsystem (second quarter 2012).
- Complete inspections of start-gas and desulfurizer subsystems (second quarter 2012).
- Issue final report for project (second quarter 2012).

Project End Date: July 31, 2011

*Congressionally directed project

Technical Barriers

This project addresses the following technical barriers from the Fuel Cells section of the Hydrogen, Fuel Cells and Infrastructure Technologies Program Multi-Year Research, Development and Demonstration Plan:

- (A) Cost
- (B) Durability
- (C) Performance
- (D) Water Transport within the Stack
- (E) System Thermal and Water Management
- (F) Air Management
- (G) Start-up and Shut-down Time and Energy/Transient Operation

Technical Targets

Carbon-based catalysts: To develop non-precious-metal catalysts for PEM fuel cells with high selectivity and durability which perform as well as conventional Pt catalysts with a cost of at least 50% less than the target of 0.2 g (Pt loading)/peak kW.

SOFC materials: Develop SOFC electrode materials that enable direct operation on hydrocarbon fuels.

Low-cost seals: Determine PEM seals materials that have no appreciable weight loss or leachants over a 60-week test period.

Hydrogen contamination: Establish the rate and mechanism of NH_3 transport in PEM cells over a 60-week period; identify the species of sulfur contamination on Pt catalysts in the presence of various gas species, e.g., H_2O and O_2 .

Multiphysics-based durability modeling: Use impedance spectroscopy to identify specific material state change driven degradation mechanisms during SOFC operation.

FY 2011 Accomplishments

- Metal-free oxygen reduction catalysts have been developed to reduce cost, facilitate manufacturing, and enhance durability of PEM fuel cells.
- Redox stable mixed ionic and electronic conductors for BSC symmetrical (and other) SOFC designs have been developed (completed 2010).
- The development of durable, low cost seals for PEM stacks, through the establishment of laboratory characterization methodologies that relate to cell/stack performance.
- Understandings and methodologies have been developed to enable the establishment of hydrogen

Fiscal Year (FY) 2011 Objectives

- Development of metal-free oxygen reduction catalysts to reduce cost, facilitate manufacturing, and enhance durability of fuel cells (Barriers A-C; Task 2-electrodes)
- Development of redox stable mixed ionic and electronic conductors for bi-electrode supported cell (BSC) symmetrical solid oxide fuel cell (SOFC) designs, to reduce cost by simplifying manufacturing, enhance durability, and greatly reduce sensitivity to thermal cycling (Barriers A-C,G; Tasks 8-portable power, 11-innovative fuel cells, 10-long term failure mechanisms)
- Development of durable, low cost seals for polymer electrolyte membrane (PEM) stacks, through the establishment of laboratory characterization methodologies that relate to cell/stack performance (Barriers A, C; Task 6-seals)
- Development of understandings and methodologies to establish hydrogen quality as it relates to PEM cell applications for transportation needs (Barriers B,C,G; Tasks 9-models for impurities, 8-portable operation)
- Development of a first principles multiphysics durability models based on interpretations of electrochemical impedance spectroscopy (EIS) data that link the multiphysics processes, the microstructure, and the material states, with cell impedance responses and global performance, mechanistically, as a foundation for engineering durability during design and manufacture of fuel cells (Barriers A-G; Tasks 9-models, 10-long term failure mechanisms, 11-innovative fuel cell design and manufacture)

quality as it relates to PEM cell applications for transportation needs (completed 2010).

- First principles multiphysics durability models based on interpretations of EIS data have been developed that form a foundation for engineering durability during design and manufacture of BSC SOFC fuel cell designs (completed 2010).

Introduction

The activities of the present project are contributing to the goals and objectives of the Fuel Cell element of the Hydrogen, Fuel Cells and Infrastructure Technologies Program of the Department of Energy through five sub-projects. Three of these sub-projects have focused on PEM cells, addressing the creation of carbon-based metal-free catalysts, the development of durable seals, and an effort to understand contaminant adsorption/reaction/transport/performance relationships at low contaminant levels in PEM cells. Two sub-projects addressed barriers in SOFCs: an effort to create a new symmetrical and direct hydrocarbon fuel SOFC designs with greatly increased durability, efficiency, and ease of manufacturing; and an effort to create a multiphysics engineering durability model based on EIS interpretations that associate the micro-details of how a fuel cell is made and their history of (individual) use with specific prognosis for long term performance, resulting in attendant reductions in design, manufacturing, and maintenance costs and increases in reliability and durability.

Approach

- Work on a previous DOE project, DE-FC36-03GO13108, was leveraged to create new carbon-based, metal-free catalysts for oxygen reduction.
- Develop new materials and material designs to create a high performance SOFC that can directly operate on hydrocarbon fuels with high power density.
- Recent advances at the University of South Carolina in controlled hydration and temperature characterization of polymer-based materials were used to establish a methodology for characterization of materials in seals in PEM stacks, and to develop a fundamental understanding how the degradation mechanisms of polymeric materials affects the performance and life of gasket/seals in PEM fuel cells.
- On-going work with the National Renewable Energy Laboratory, Argonne National Laboratory, Savannah River National Laboratory, and Los Alamos National Laboratory formed a foundation for the work on developing an understanding of the contaminant adsorption/reaction/transport/performance relationships at low contaminant levels in PEM cells. The study provided equilibrium and rate constants

suitable for use in new and existing models, and in computer codes at Argonne National Laboratory.

- Conceptual foundations laid by research supported by the National Science Foundation, the Air Force Office of Scientific Research and several industries including United Technologies Fuel Cells were expanded to create a multiphysics engineering durability model based on electrochemical impedance spectroscopy interpretations that associate the micro-details of how SOFC fuel cells are made and their history of individual use with long term performance, to achieve reductions in design, manufacturing and operating costs.

Results

Only one example of salient results is presented in the limited space available here. Other results appear in the quarterly reports.

Project 1. Development of Carbon Composite Electro Catalyst for the Oxygen Reduction Reaction (ORR) – Dr. Branko Popov

Objectives

- Synthesize carbon-based metal-free catalysts and carbon composite catalysts for ORR.
- Optimize catalytic active reaction sites as a function of carbon support, surface oxygen groups, nitrogen content, surface modifiers, pyrolysis temperature and porosity.

Technical Barriers

This project addresses the following technical barriers from the Fuel Cells section of the Hydrogen, Fuel Cells and Infrastructure Technologies Program Multi-Year Research, Development and Demonstration Plan:

- Cost
- Durability
- Performance

Technical Targets

- Non-Pt catalyst activity per volume of supported catalyst $>130 \text{ A cm}^{-3}$ (stack) at 0.8 internal resistance (iR_{free}).
- Cost: at least 50% less than a target of 0.2 g (Pt loading)/peak kW.

- Durability: >2,000 h operation with less than 10% power degradation.

Accomplishments

- The non-precious metal catalysts (NPMCs) with the exceptional activity and stability for oxygen reduction in alkaline electrolyte are developed by introducing N-based active sites.
- The pyridinic-N and graphitic-N are believed to play important roles in the active sites of NPMCs.
- The NPMCs shows comparable performance with Pt/C in alkaline fuel cells with the open circuit potential of 0.97 V and maximum power density of 177 mW cm⁻².

Introduction

Pt and Pt-based alloy catalysts are widely used in PEM fuel cells because of their high catalytic activity and selectivity as well as high corrosion resistance. In the last few years, several transition metal compounds such as macrocycle-based metal porphyrin system, chevrel phase-type compounds and other transition metal chalcogenides have been proposed as selective catalysts for ORR. However, significant increase in activity and stability of the catalyst is still essential for PEM fuel cell applications. The goal of this project is to develop highly active and stable carbon-based metal-free catalysts and carbon composite catalysts with strong Lewis basicity (π electron delocalization) to facilitate ORR.

We have systematically studied the activity and stability, as well as the nature of active sites of NPMCs for the ORR. In this work, the NPMC with high activity and stability in alkaline electrolyte was developed. The fuel cell performance of the catalyst was studied using an anion exchange membrane fuel cell.

Approach

The approach used to synthesize the catalyst includes the following steps: (i) the modification of a porous carbon black support; (ii) the deposition of Co-N or Co-Fe-N chelate complex on the support; (iii) the first high-temperature pyrolysis; (iv) the chemical post-treatment (acid leaching); and (v) the second high-temperature pyrolysis.

Results

Figure 1a shows polarization curves for oxygen reduction of NPMC heat-treated at 900°C (NPMC-900 or CoFeN/C-HLH) before and after potential cycling in 0.1 M KOH. The cycling was performed in N₂-saturated 0.1 M KOH with a scan rate of 10 mV s⁻¹ between 0.8-1.2 V vs. the reference hydrogen electrode. The polarization curves

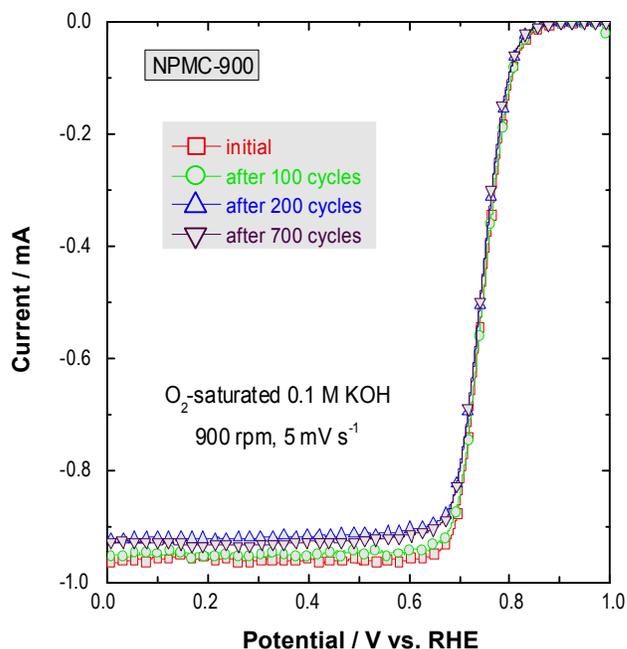

FIGURE 1A. Polarization curves for the oxygen reduction reaction in O₂-saturated 0.1 M KOH of NPMC heat-treated at 900°C before and after the potential cycling stability test; scan rate: 5 mV s⁻¹; rotation rate: 900 rpm.

were measured before and after 100, 200, and 700 cycles, respectively. It is evident that the NPMC-900 catalyst does not show any performance degradation during 700 cycles indicating that the catalyst is very stable in alkaline solution.

Figure 1b shows the X-ray photoelectron spectroscopy (XPS) spectra of N_{1s} for the NPMC-900 before and after the potential cycling stability test in 0.1 M KOH. The peaks of N_{1s} at 398.6 ± 0.3 eV, 401.3 ± 0.3 eV, and 403.3 ± 0.3 eV can be attributed to the pyridinic-N, graphitic-N, and pyridine-N-oxide, respectively. The pyridinic-N and graphitic-N are believed to be active catalytic sites for oxygen reduction. As shown in Figure 1b, the profile of the N_{1s} spectra of NPMC-900 is still similar to that of fresh catalyst indicating high stability of NPMC for oxygen reduction in alkaline electrolytes.

The kinetic parameters for oxygen reduction reaction on CoFeN/C subject to heat-treatment, leaching, and re-heat-treatment (CoFeN/C-HLH) and Pt/C catalysts including the ring currents, the numbers of electron exchanged and polarization curves were obtained using a rotating ring disc electrode (RRDE) system in O₂-saturated 0.1 M KOH. Figure 2 summarizes the RRDE results. The data of carbon black are also presented for comparison. The ring currents were measured on a Pt ring electrode held at 1.2 V for CoFeN/C-HLH and Pt/C catalysts. It is evident that the ring currents for CoFeN/C-HLH and Pt/C are comparable. In contrast, the ring current for carbon is much higher. The number of electrons exchanged in the redox reaction for CoFeN/C-HLH and Pt/C is 3.9-4.0 at high potentials.

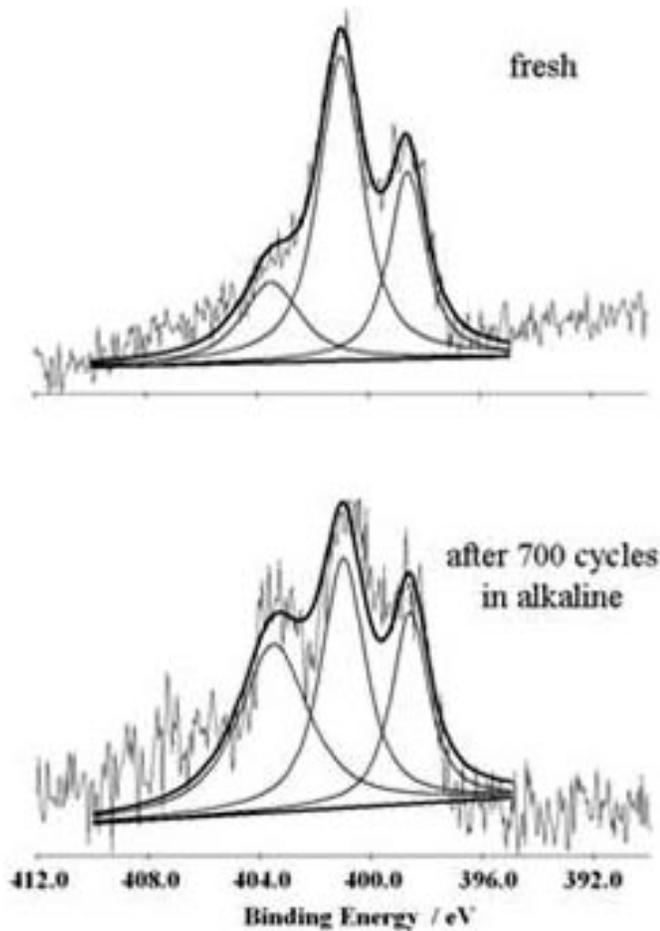

FIGURE 1B. XPS spectra of N1s obtained for: (a) fresh NPMC and for catalyst cycled 700 cycles in 0.1 M KOH.

The results indicate that both CoFeN/C-HLH and Pt/C catalysts catalyze the ORR mainly via a four-electron pathway in alkaline electrolyte. For carbon black alone, a lower selectivity with number of electrons exchanged in the range of 3.3-3.6 was observed at high potentials. The catalytic performance of CoFeN/C-HLH is comparable with Pt/C for oxygen reduction in alkaline electrolytes.

Figure 3 shows the preliminary performance of a H₂-O₂ anion exchange membrane fuel cell. The operation temperature is 50°C. The Pt loading at anode is 0.4 mg cm⁻², whereas the catalyst loadings at cathode are 4 mg cm⁻² for CoFeN/C-HLH and 0.4 mg_{Pt} cm⁻² for Pt/C. Anode and cathode gases are humidified at 50°C. The flow rates of H₂ and O₂ are 200 and 400 mL min⁻¹. The open circuit potentials are 0.97 and 1.04 V for CoFeN/C-HLH and Pt/C, respectively. The maximum power densities are 177 and 196 mW cm⁻² for CoFeN/C-HLH and Pt/C, respectively. At high potential, the performance of CoFeN/C-HLH is slightly lower than Pt/C. At intermediate potential, they show very similar performance. The lower performance of

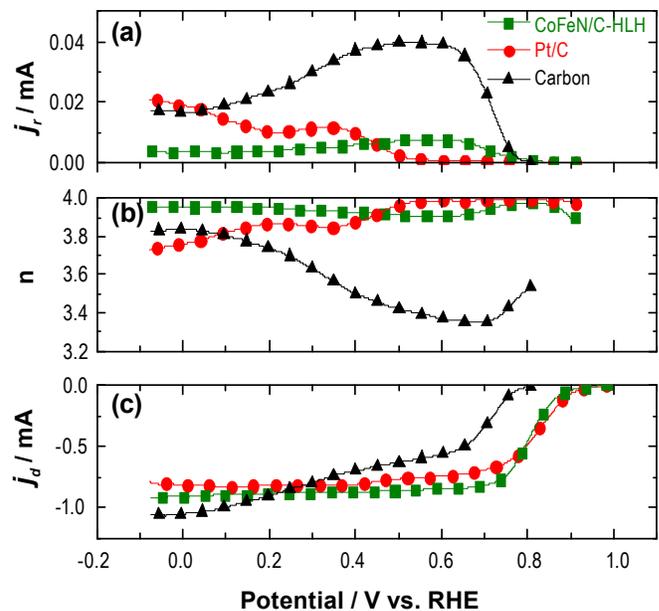

FIGURE 2. Comparison of CoFeN/C-HLH and Pt/C catalysts for the oxygen reduction reaction in O₂-saturated 0.1 M KOH. Scan rate: 5 mV s⁻¹; rotation rate: 900 rpm. (a) ring currents; (b) the number of electron exchanged during oxygen reduction; (c) polarization curves.

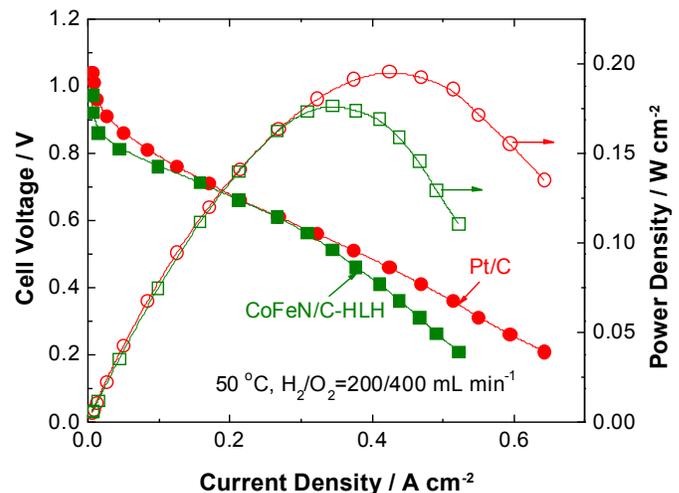

FIGURE 3. Preliminary performance of a H₂-O₂ anion exchange membrane fuel cell. The operation temperature is 50°C. The Pt loading at anode is 0.4 mg cm⁻², whereas the catalyst loadings at cathode are 4 mg cm⁻² for CoFeN/C-HLH and 0.4 mg_{Pt} cm⁻² for Pt/C. Anode and cathode gases are humidified at 50°C. The flow rates of H₂ and O₂ are 200 and 400 mL min⁻¹.

CoFeN/C-HLH over Pt/C at low potential may be attributed to higher mass-transfer resistance of the former resulting from higher catalyst loading and thus higher thickness of catalyst layer.

Conclusions and Future Directions

- NPMCs for oxygen reduction in alkaline electrolyte are developed by heating metal-nitrogen containing chelates followed by chemical post-treatment.
- The pyridinic-N and graphitic-N supported on graphitized carbon are active sites for oxygen reduction with high stability in alkaline electrolytes.
- The NPMCs exhibits comparable performance with Pt/C in anion exchange membrane fuel cells with the open circuit potential of 0.97 V and maximum power density of 177 mW cm⁻².

Future work includes the following tasks:

- Hydrogen Quality - Extract rate constants from experimental data for the case of a contaminant that desorbs from the catalyst surface; establish correlations between experimental data and model that will allow predictions of the effect of contaminant concentration and electrode potential.
- Carbon Composite Catalyst – Confirm protocol for preparation of mesoporous carbon support; improve integrity of the carbon composite catalyst layer in the membrane electrode assembly (MEA); reduce MEA resistance by decreasing the catalyst layer thickness and by increasing the specific gravity and activity of the catalyst.
- Hydrocarbon-Fueled SOFC - Evaluate solid oxide fuel cell performance using hierarchically porous electrode and LaGaO₃- as well as SFM-based ceramic anode.
- Gaskets and Seals - Design new compression set tests to include various compression strains and more realistic heating/cooling cycles to fuel cell operation; develop a life prediction model; and compare the performance of several off-the-shelf seal materials in the fuel cell environment.
- Durability Modeling in SOFC - Complete button cell test system and EIS test protocols; complete conductivity model of bi-supported cell electrode configuration.

Special Recognitions & Awards/Patents Issued

1. Prof. Ken Reifsnider, PI of this effort, is Director of the DoE Energy Frontiers Research Center on Heterogeneous Functional Materials, the “HeteroFoaM Center.”
2. The Crystal Flame Innovation Award in Research from FuelCell South was presented to Dr. Popov’s research group for research work in the field of non-precious catalyst development and preparation thin film assemblies with nano-structured catalysts and the development of the pulse deposition technique for preparation of membrane electrode assemblies.

Project End Date: July 31, 2011

*Congressionally directed project

Technical Targets

Reliability of the fuel cell system BOP components is a critical factor that needs to be addressed prior to fuel cells becoming fully commercialized. Failure or performance degradation of BOP components has been identified as a life-limiting factor in fuel cell systems [1]. The goal of this project will be to develop a series of test beds that will test system components such as pumps, valves, sensors, fittings, etc., under operating conditions anticipated in real PEM fuel cell systems. Results will be made generally available to begin removing reliability as a roadblock to the growth of the PEM fuel cell industry.

Stark State College students participating in the project, in conjunction with their coursework, will gain technical knowledge and training in the handling and maintenance of hydrogen, fuel cells and system components as well as component failure modes and mechanisms. This fuel cell work force development program will result in students trained in PEM fuel cell system technology.

TABLE 1. Progress towards Meeting Technical Targets for BOP Components for Transportation Applications

Characteristic	Units	2010/2015 Stack Targets	2011 Project Status
Durability with cycling at operating $T \leq 80^{\circ}\text{C}$	Hours	5,000	To be determined

Fiscal Year (FY) 2011 Objectives

There are two primary objectives of this project:

- To establish a testing project resulting in a reliability database for candidate proton exchange membrane (PEM) fuel cell balance-of-plant (BOP) components.
- To enhance the education of the technical workforce trained in PEM fuel cell system technology.

Technical Barriers

This project addresses the following technical barriers from the Fuel Cells section of the Fuel Cell Technologies Program Multi-Year Research, Development and Demonstration Plan:

(A) Durability

This project also addresses the following technical barrier from the Education section of the Fuel Cell Technologies Program Multi-Year Research, Development and Demonstration Plan:

(D) Lack of Educated Trainers and Training Opportunities

FY 2011 Accomplishments

- Students are being trained on the construction, programming and operation of the life cycle test beds.
- Commercial off-the-shelf test components have been identified based on functionality, cost and size.
- Candidate sensors have been purchased, integrated and tested in the test beds.
- Testing protocols have been designed for each component.
- Students have:
 - Fabricated third testbed.
 - Fabricated and tested housing and electrical design for sensors.
 - Implemented I^2C protocol.
 - Incorporated Hydrogen Safety Plan protocol in testbed operation.

Introduction

One of the major challenges that must be addressed by the fuel cell industry prior to commercialization is the reliability of the components of a system. To this end Stark State College of Technology and Lockheed Martin have teamed to address this critical factor.

Approach

Stark State College of Technology and Lockheed Martin have developed a series of test beds that test fuel cell system components such as pumps, tubing types, sensors, valves etc., operating under conditions anticipated in real PEM fuel cell systems. The test beds operate under various conditions continuously. Parts that continue operating demonstrate lifetime for potential fuel cell systems. Parts that have failed are removed and examined to learn the cause of the failure. Feedback will allow manufacturers to improve the products for future use in PEM fuel cells. Results will allow for a path towards removing reliability as a roadblock to the growth of the PEM fuel cell industry. A total of three test beds have been developed for this project; two at Stark State College of Technology and one at Lock Martin. In each case students in the engineering technology will monitor the test beds as part of their education program.

Results

A fuel cell system consists of a fuel cell and its supporting BOP – the pumps, valves, sensors, fittings, piping, etc. needed to turn a fuel cell into a useful power plant. Components in this complex system can have long-term exposure to hydrogen, air (oxygen), high purity water, heat and other chemicals. The BOP reliability test beds will be a simplified design, simulating the conditions of an operating fuel cell. The first two test beds are designed to replicate humidified hydrogen exposure in the PEM fuel cell at $\leq 80^{\circ}\text{C}$. These test beds are a hydraulic loop simulation of the fuel cell system to test the piping, connectors, sensors, valves, pumps, etc., without the fuel cell. Testing will be done to simulate the flow rates, temperature and pressure of operation, initially under a humidified nitrogen system with eventual operation under reactant conditions. This exposure would simulate the anode flow areas just before the fuel cell entrance and conditions in the hydrogen re-circulation loop. The humidified hydrogen would be circulated using a hydrogen blower such as the Parker Hannifin Model 55™ Univane rotary compressor [2].

Figure 1 shows the test bed process flow diagram. The test bed design can be viewed as two “separate” pieces. The upper flow diagram designated “Life Cycle Test” is the loop that will circulate humidified hydrogen. This loop will be

Dynamic Response Test
 Pre- and Post- Test
 Assessment

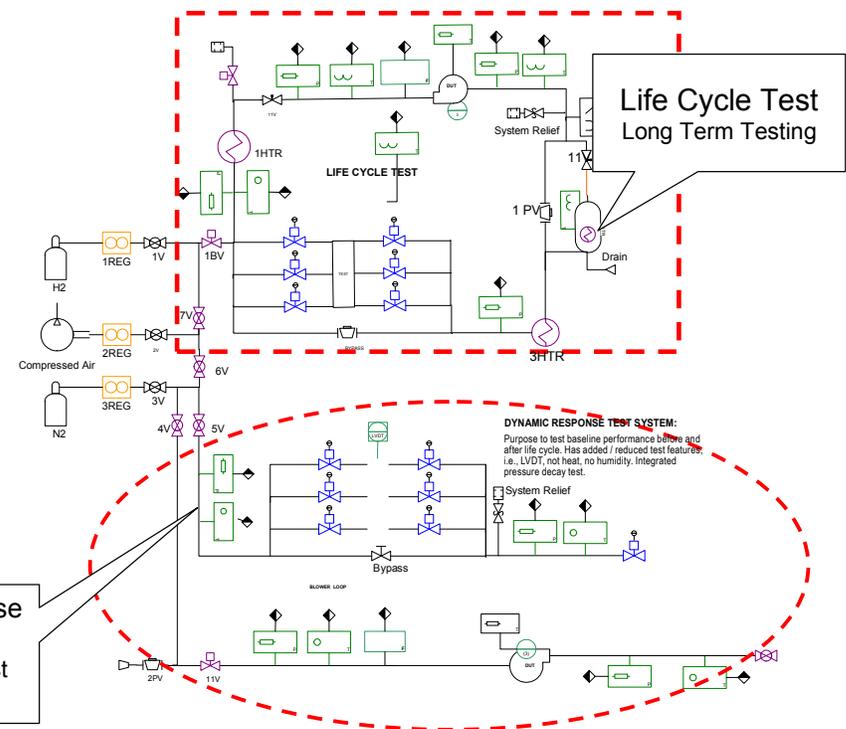

FIGURE 1. Fuel Cell BOP Reliability Test Bed Design

pre-tested with nitrogen for leaks before hydrogen usage. Operating conditions will be 50 psi static, 80°C, 70-95% relative humidity and 6-7 SCFM flow rate in the closed-loop system. The lower loop is designated for dry nitrogen or air only. The lower loop consists of the blower platform and the dynamic response test system. This section is for the pre- and post-test validations in our reliability testing, pump performance mapping, and pressure decay (leak) testing of the components.

A LabVIEW-based data acquisition program has been written for each test stand to log critical experimental parameters. Pressure, temperature and humidity sensors are currently under test. The testing protocol consisted of comparison of devices under test with traceable probes. The device then underwent testing to verify accuracy, measuring range and short term stability before longer term testing. Figures 2 and 3 show example evaluation testing for candidate pressure transducers. The system transducers

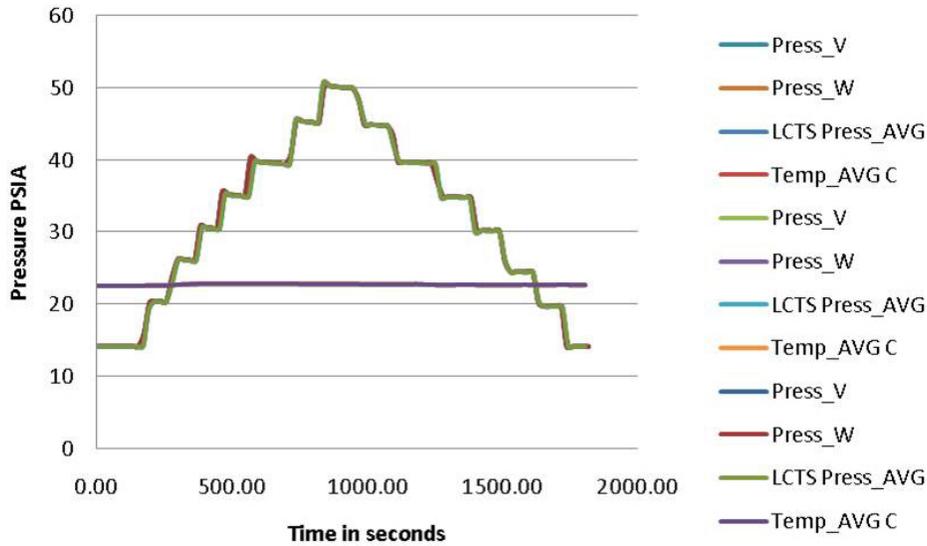

FIGURE 2. Testing Performance of Pressure Sensors

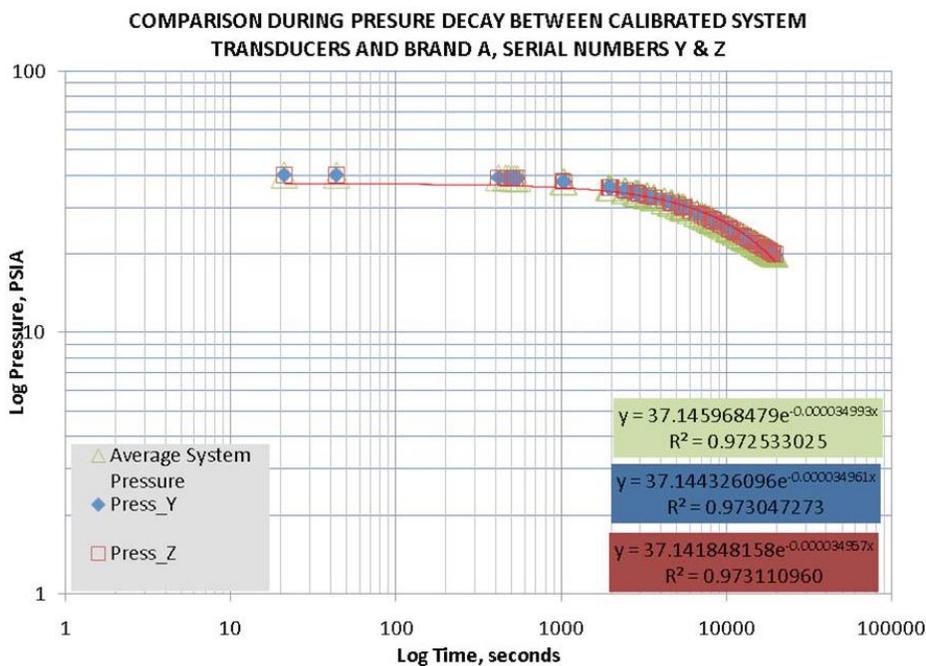

FIGURE 3. Pressure Decay Comparison

are traceable to the National Institute of Standards and Technology using a HEISE PTE-1 Calibrator with 0-200 psig pressure module to 0.02% accuracy.

A trade study of pressure sensing elements led to a product decision matrix of low-cost pressure transducers from large original equipment manufacturers. Of the transducers specified and evaluated thus far, two failures, one soft and one hard failure, have occurred under time conditions less than the PEM BOP and manufacturer's ratings. Sensors that have qualified continue to be tested on the Life Cycle testbed, exposed to high temperatures and humidity.

Low-cost, lightweight precision temperature sensors, typically procured in high quantities, required repackaging in a form that would impose negligible impedance on performance. These sensors were built-in with a high performance epoxy encapsulant of very high thermal conductivity and very low electrical conductivity. Evaluation of the temperature sensors and several encapsulation designs are continuing on the Life Cycle testbed. Integrated humidity and temperature sensors, in compact, lightweight form are also under test. These sensors utilize the I²C protocol for allowing upward of 100 sensors to be connected serially to a single data bus, eliminating the need for multiple controller cards. Special housings were also designed for these sensors and fabricated. Humidity/temperature sensors are currently being evaluated in the Life Cycle testbed.

Student training has been ongoing for the operation of the testbed. The training has continued for participating students to have a greater depth of understanding in LabVIEW programming and exposure to a broader range of software programming techniques to implementation of the I²C protocol. Training has included embedded controller information for LabVIEW programming and compiling to make a stand-alone program for data acquisition, control and analysis of the data, implementation of testing protocol, as well as compliance with the Hydrogen Safety Plan protocol.

Conclusions and Future Directions

- Further characterization of lower cost sensors over a wider range of test conditions.
- Further refinement of sensor housing and electronics for lower price sensors.
- Investigation of electrical actuated valves including modifications for improving flow, lowering power consumed and decreasing size and weight [3].
- Permeation testing of different tubing materials.
- The future is being planned with students being trained on the construction, programming and operation of the life cycle test beds.
- A one year extension no cost extension has been requested.

*Congressionally directed project

Fiscal Year (FY) 2011 Objectives

- Develop solid oxide fuel cell (SOFC) materials and architectures for robust operation on renewable/ biomass fuel streams.
- Identify optimal fuel-processing strategies for renewable fuels, specifically biogas derived from anaerobic digesters commonly utilized for sludge remediation at wastewater treatment facilities.
- Employ system modeling to optimize SOFC system configurations.
- Extend model-predictive control strategies to integrate system hardware for improved load following and dynamic response.

Technical Barriers

- Durability: Broaden SOFC operating windows under hydrocarbon and bio-derived fuel streams.
- Balance-of-plant costs: Integrate fuel reforming and heat recuperation hardware into a single low-cost ceramic micro-channel reactive heat exchanger.
- Performance: Increase efficiency and decrease costs through system optimization and balance-of-plant component development and integration.
- Transient operation: Develop model-predictive control algorithms for use in dynamic control.

This project addresses the following technical barriers from the Fuel Cells section of the Fuel Cell Technologies Program Multi-Year Research, Development and Demonstration Plan:

- (A) Durability
- (C) Performance
- (G) Start-up and Shut-down Time and Energy/Transient Operation

Technical Targets

In this project, we conduct a range of studies to improve the durability, efficiency, and transient operation of SOFC systems. Fuel streams for these systems include anaerobic digester-derived biogas. Insights gained from these studies will be applied toward the design and synthesis of SOFC materials and systems to meet the DOE 2015 Technical Target for durability (35,000 hours), start-up time (15-30 minutes), and cycle capability (250 cycles).

FY 2011 Accomplishments

- Demonstrated over 16 days of continuous SOFC power generation on unreformed simulated biogas (65% CH₄ + 35% CO₂).
- Established biogas fuel processing strategies and operating windows for upstream conversion of biogas into syngas.
- Quantified performance of SOFCs under biogas reformate fuel streams, and established performance comparisons under hydrogen fuel streams.
- Developed hybrid computational fluid dynamics (CFD)-chemical kinetics model to examine design tradeoffs in ceramic microchannel fuel reformer/heat exchanger.
- Utilized computation models to examine thermal, chemical, and electrochemical fields within tubular SOFC stack.
- Developed rapid, lower-order dynamic models to map response of slower, high-order physical models for use in dynamic system control of fuel-reformer hardware.

Introduction

The objective of this project is to advance the current state of technology of SOFC systems to improve performance when operating on biomass-derived fuel streams. The target fuel stream is “biogas” (~65% CH₄/35% CO₂) generated by the anaerobic digesters that are widely used for treatment of sludge in

municipal wastewater treatment facilities. In this project, we are developing new SOFC materials and architectures to improve the robustness of systems operating under biogas. Additionally, modeling and experimentation is being conducted to examine performance tradeoffs across numerous fuel-processing strategies for this fuel. Fuel-reforming processes are being integrated with exhaust gas recuperation processes through development of a single low-cost ceramic microchannel reactive heat exchanger, created in collaboration with industrial partner CoorsTek, Inc. System-level models are being used to predict SOFC system efficiencies under biogas fuels utilizing the fuel-reforming microchannel-reactor integration strategies under development. Model-predictive control strategies are being developed and applied to improving the dynamic response of the fuel-reformer hardware.

Approach

The Colorado School of Mines (CSM) has assembled a strong and diverse team of scientists and researchers with broad skill sets applicable to fuel cell development. Coordinated through the Colorado Fuel Cell Center, this team examines both the fundamental underpinnings and the key technical problems facing SOFC operation under biomass-derived fuel streams. We develop new SOFC materials and architectures to address the technical challenges and operating windows associated with SOFC operation on biomass-derived fuels. Through development of low-cost ceramic microchannel reactive heat exchangers with industrial partner CoorsTek, Inc., we create system-integration strategies to combine balance-of-plant processes into single hardware units, increasing system simplicity and decreasing cost. A range of computational models are developed to examine the physical processes underway during SOFC and fuel-reformer operation. Model-predictive control strategies are created and applied to fuel-reforming hardware in an effort to improve the dynamic response of SOFC systems.

Results

SOFC Materials and Architectures: Barrier Layers for Improved Robustness

Fuel cell reliability and performance can be greatly improved through development of new materials and architectures that promote robust SOFC operation on renewable and hydrocarbon fuels. In this task, we are currently developing new SOFC anode architectures utilizing anode “barrier layers” that mitigate carbon-deposit formation, seeking to optimize the structure of the cell for maximum efficiency and reliability. A conceptual drawing of a tubular SOFC with an inert barrier layer is shown in Figure 1a. The barrier layer reduces the transport of electrochemically produced steam out of the anode support. This increases the concentration of steam within the

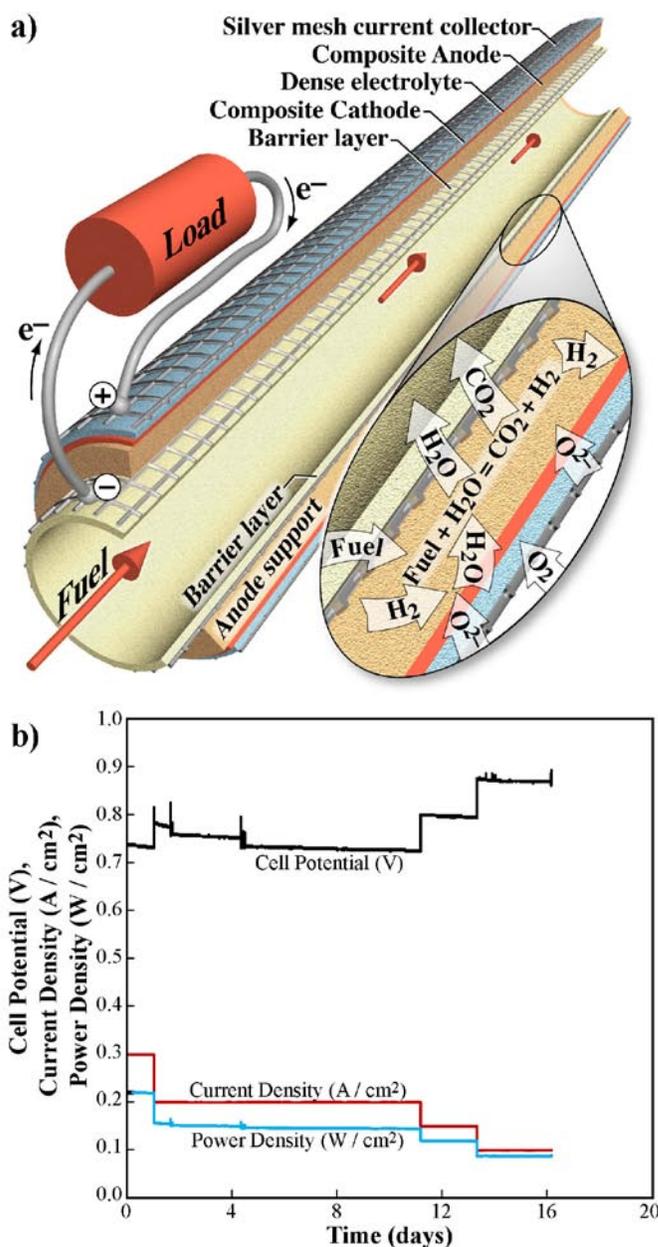

FIGURE 1. a) Illustration of a tubular SOFC employing an anode barrier layer with inset depicting internal-reforming processes; b) extended operation of barrier-layer equipped tubular SOFC under direct biogas fuel. Step changes represent changes in load applied to the cell.

support, promoting methane internal-reforming reactions over solid-carbon-forming reactions, preventing carbon deposition and cell deactivation.

During the previous year, we successfully integrated a barrier layer into a tubular CoorsTek SOFC, and continuously operated this assembly under a simulated humidified biogas fuel stream (63% CH_4 + 34% CO_2 + 3% H_2O). Biogas is a byproduct of anaerobic-digestion processes widely utilized in landfills and wastewater-treatment facilities for sludge remediation. Some cleaning

of biogas is generally required to remove siloxanes and sulfur-containing species upstream of biogas-fueled power generators. In this project, biogas is synthesized from near-pure compressed-gas cylinders to simulate the cleaned biogas fuel composition. The barrier-layer equipped SOFC continuously converted the chemical energy in the simulated biogas into electricity for over 16 days with negligible performance degradation as shown in Figure 1b. No biogas fuel reforming upstream of the SOFC was conducted. The barrier layer was fabricated in the Colorado Fuel Cell Center by slip-casting of lanthanum-doped strontium titanate ($\text{Sr}_{0.8}\text{La}_{0.2}\text{TiO}_3$). The CoorsTek SOFC utilizes fairly conventional materials, including a yttria-stabilized zirconia (YSZ) electrolyte, nickel-YSZ anode, and strontium-doped lanthanum manganate cathode. Testing was conducted at 850°C under very low fuel utilization in order to present a “worst-case” scenario for carbon-deposit formation. Steady operation was observed at each current density. This result presents the first long-term operation of a barrier-layer-equipped tubular SOFC under simulated biogas fuel, and the first multi-day performance of an SOFC on unreformed simulated biogas fuel.

Biomass-Derived Fuel Processing

In this task, we examine fuel-reforming strategies to convert biogas into syngas for subsequent electrochemical conversion in SOFCs. Upstream reforming of biogas prior to introduction into the SOFC stack presents a nearer-term solution to SOFC operation on biogas in comparison to barrier-layer architectures. The goal is to develop flexible, efficient fuel-processing strategies for the robust use of biogas fuels in SOFCs. The effort includes computational model development of biogas fuel reforming, experimental validation, and electrochemical performance measurements of biogas-reformate-fueled SOFCs. As part of this task, we examine the relationship between SOFC performance and biogas fuel-reforming approach, contrasting results of steam reforming with catalytic partial oxidation (CPOX) using air, and CPOX using oxygen. While CPOX with oxygen may at first seem impractical, many wastewater treatment facilities utilize cryogenically stored pure oxygen to decrease energy usage during waste-aeration processes. Such an oxygen source could potentially be utilized by a co-located SOFC electric generator.

During the previous year, a series of numerical and physical experiments were conducted to quantify biogas-reformate composition across a number of reforming approaches and operating conditions. Both modeling and experimentation focused on use of a rhodium-based catalyst on a porous alumina foam support. The operating conditions probed included reforming temperature, steam-to-carbon ratio, oxygen-to-carbon ratio, and space velocity. Computational modeling was first conducted to identify optimal biogas-reforming conditions over a wide operational space. These numerical results were then analyzed, and

then experimentally validated for select conditions with high methane-conversion levels.

The high CO_2 content of biogas can result in surprising reformate compositions. Through dry-reforming reactions ($\text{CH}_4 + \text{CO}_2 \rightarrow 2 \text{CO} + 2 \text{H}_2$), the biogas-borne CO_2 is reduced to CO. Higher reforming temperatures are required to drive this endothermic reaction. Within the SOFC anode, carbon monoxide is further internally reformed through the water-gas shift reaction ($\text{CO} + \text{H}_2\text{O} \rightarrow \text{CO}_2 + \text{H}_2$). Thus the CO generated from CO_2 during dry reforming directly leads to additional H_2 formation within the cell. This additional H_2 is in-turn electrochemically oxidized, resulting in additional electricity generation. Because of internal reforming, it is important to consider the CO content of the reformate as a fuel in the SOFC. Generating reforming conditions that maximize conversion of biogas-borne CO_2 to CO is critical to realizing peak efficiency. Increased dry reforming decreases the parasitic thermal requirements for addition of steam or air oxidizers to reform the biogas into syngas.

Our experimental and modeling efforts found that while steam reforming generates the highest H_2 mole fraction in the reformate (~54%), the combined $\text{H}_2 + \text{CO}$ mole fraction reaches only 78%. In contrast, biogas reforming via CPOX with O_2 results in a combined $\text{H}_2 + \text{CO}$ mole fraction of nearly 86%, and 10% higher utilization of the biogas chemical potential. This potential benefit comes with the added simplicity of the CPOX system design, as catalytic partial oxidation is a far more elegant reforming approach in comparison to that of steam reforming. Such results may prove valuable to engineers and scientists that design biogas-fueled SOFC systems.

After establishing the desired reforming conditions and reformate compositions for each of the three different approaches, SOFC electrochemical performance under the different reformate compositions was measured. Using the experimental results from the simulated-biogas reforming experiments, biogas reformate was synthesized and supplied to a tubular SOFC operating at 800°C in the Colorado Fuel Cell Center. An important aspect to the performance testing was ensuring that each test resulted in the same utilization of the supplied fuel (70%), and that each cell was operated at the same electric potential (0.65 V). Performance on reformate was compared to that under hydrogen fuel, with results shown in Figure 2.

Not surprisingly, the highest performance was observed under hydrogen-fuel conditions. Power density under reformate generated via CPOX using O_2 is 0.145 W/cm², only 3% lower than that of the pure-hydrogen condition (~0.15 W / cm²). In contrast, cell performance under reformate generated by steam reforming and CPOX with air is approximately ~0.124 W/cm², nearly 20% lower than the hydrogen condition. These electrochemical-performance differences can have significant impacts on the size, footprint, and cost of biogas-fueled SOFC systems.

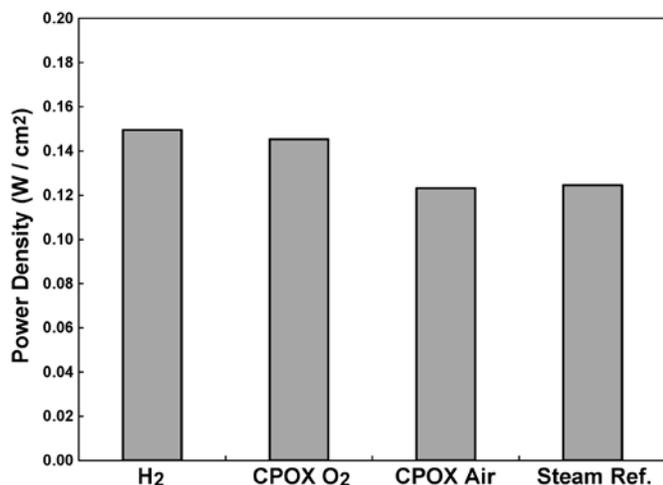

FIGURE 2. SOFC electrochemical performance at 0.65 V and 70% utilization under hydrogen and biogas-reformate fuel streams.

Ceramic Microchannel Reactors

Building on the biogas-reforming results, we are now configuring our ceramic microchannel reactor technology for biogas reforming. An illustration of this reactor is shown in Figure 3a and 3b. The reactor is fabricated by industrial partner CoorsTek, Inc. using low-cost ceramic materials (Al_2O_3) that are joined in a single high-temperature sintering process. This greatly reduces the materials and fabrication costs of the heat-exchanger device, with significant potential for decreasing SOFC balance-of-plant expenses. These microchannel reactors offer great advantages over conventional shell-and-tube reactors through improved heat transfer and thermal regulation of reforming processes. Exothermic reforming processes can cause hot spots in conventional reactors that reduce the efficiency and effectiveness of the reforming process. Similarly, supplying heat for endothermic-reforming processes can pose significant parasitic losses in SOFC systems. In microchannel reactors, the hot and cold streams are tightly integrated, so that thermal regulation, reforming activity, and reformate selectivity are maximized.

We are developing deposition processes of catalyst materials within the microchannel reactor. Sealing and manifolding of the microchannel reactors is also an area of development, with manifolding design and testing ongoing. An important aspect to our microchannel-reactor effort is the development and application of high-fidelity computational models to guide reactor design and operation. ANSYS-FLUENT CFD models are being modified to incorporate elementary chemical kinetic mechanisms for high-fidelity modeling of fuel reforming within the microchannel reactor. Such incorporation of elementary chemistry into CFD models is quite challenging; CSM is working directly with ANSYS-FLUENT developers on this effort.

Characteristic methane-steam-reforming results from the hybrid CFD-kinetics model are shown in Figure 3c and 3d.

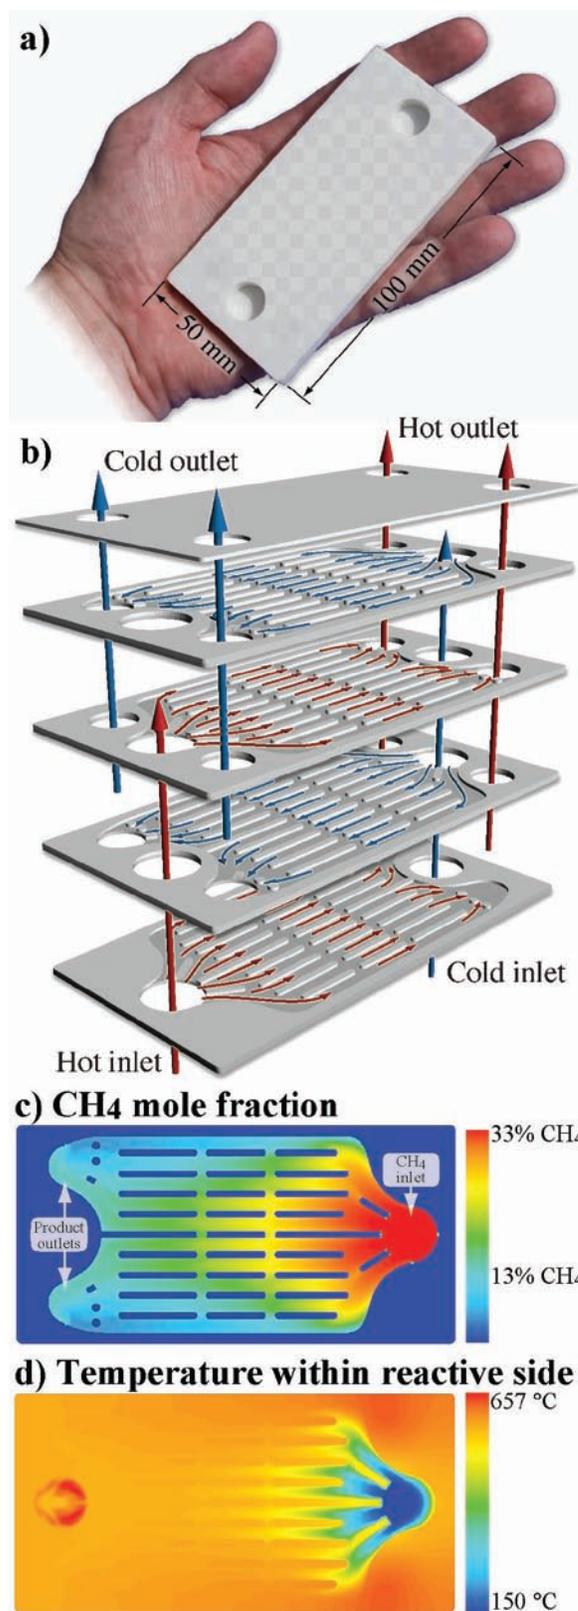

FIGURE 3. a) Image and b) exploded illustration of ceramic microchannel reactor; c) results from hybrid CFD-chemical kinetics model predicting methane mole fraction and d) temperature fields over the catalytically active layer of the microchannel reactor.

The catalytically active layers are fed with a methane–steam mixture at a ratio of 1 CH₄ : 2 H₂O flowing from the inlets at the right to the outlets at the left at a flow rate of 4 SLPM and temperature of 150°C. The model catalyst is rhodium, which has exceptional methane–steam–reforming activity and resistance to carbon-deposit formation. The heterogeneous reforming chemistry takes place on the walls of the catalytically active layers within the microchannel reactor. The non-reactive backing channels are fed with air flowing at 60 SLPM and an inlet temperature of 800°C. The hybrid model solves the complete three-dimensional flow field, and the conjugate heat transfer between the two inlet gas streams and the solid ceramic reactor body. These operating conditions result in 51% conversion of methane. The methane–steam inlet gas is heated from 150°C to reforming temperature within the first bank of microchannels, with reactions taking place primarily in the first and second banks of channels. Flow uniformity is reasonable, though some improvements seem possible. Peak temperatures within the reactive side reach approximately 600°C, a bit lower than desired for optimal steam reforming. This temperature could be increased through higher flow rates of the air supplied to the non-reactive backing channels, or higher inlet temperatures of either the air or the reactive methane–steam mixture.

This result demonstrates the application of a powerful research and development tool in which three-dimensional computational fluid dynamics and heat transfer are coupled to high-fidelity elementary chemical kinetics. Over the remainder of the project, we will utilize this tool to define operating windows for biogas reforming that result in high methane conversion and high selectivity to hydrogen and carbon monoxide.

System-Level Modeling

The complex component geometries of the SOFC hot zone and the chemical and electrochemical reactions within are coupled with heat transfer and three-dimensional fluid flow to simulate hot zone thermal energy management of representative SOFC geometries. A central feature of this task is to accurately capture the three-dimensional transport phenomena within the hot zone and derive representative reduced-order models. In this task, these reduced-order models are directed towards use in system process design and parameter specification. The domain of the CFD model includes the entire cathode and stack endplates along with the majority of the recuperator, fuel/air preheat flow, and system insulation. The hot zone is modeled after the 600-W tubular SOFC stack developed by industrial partner Protonex Technology Corporation.

A characteristic result is shown in Figure 4. It is increasingly clear that the outer tubes located near the periphery act as radiation shields, keeping inner-radii tube groups warmer. Local species concentration fields identify of critical O₂-depletion zones. These results and modeling

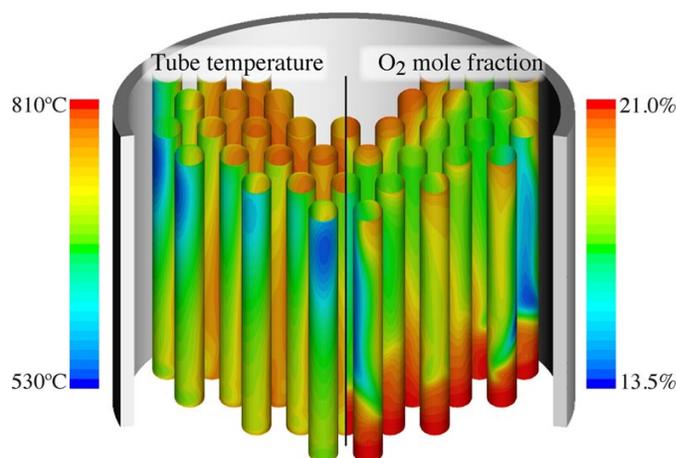

FIGURE 4. Model Predictions of Thermal and Oxygen-Concentration Fields across 600-W Tubular Stack

tools can be utilized by stack developers to improve stack design, performance, and efficiency.

Model-Predictive Control

Dynamic control efforts have focused on the effects of balance-of-plant components on performance and control. The balance-of-plant components of the stack include the fuel reformer, air and fuel blowers, heat exchanger, and tail-gas-combustion burner. A complete SOFC system is highly connected via the temperatures and mass compositions that flow through each of these components. As such, model-based dynamic control must incorporate the dynamics of all balance-of-plant components within safe operating limits. For example, the reformer outlet gas composition must be controlled in order to prevent carbon deposition within the stack. At the same time, carbon deposition is dependent upon the stack operating temperature and power level, which drives the operation of the reformer. Additionally, limits on reformer catalyst temperature need to be maintained while ensuring the mass flow and fuel composition provided to the stack are sufficient for the desired current output. The stack air temperature must also be high enough to prevent stack excessive stack cooling. It is for these reasons, that a system-wide control-oriented dynamic model is needed.

Current work has provided a system-wide model consisting of the fuel reformer, tubular SOFC stack, and heat exchanger. Improvements over existing system-wide models include the use of component models that allow for composition estimation throughout the system. Although increasing the required model complexity, composition is highly coupled with both performance of the system and robustness to real-world inputs. A characteristic result of this model is shown in Figure 5, which shows that even small changes on the inlet fuel composition to the fuel reformer has impacts on the stack performance.

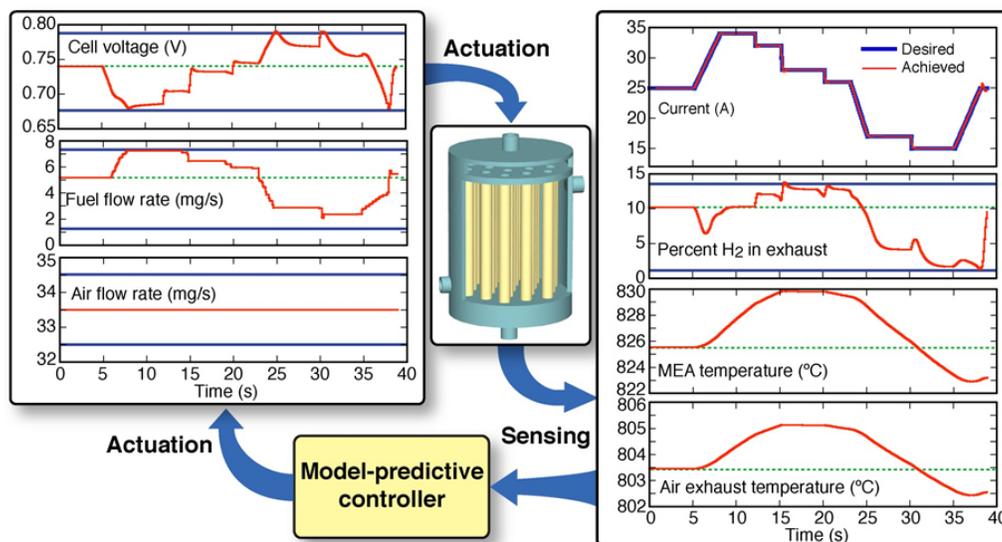

FIGURE 5. Dynamic Response Predictions from Model-Predictive Control Algorithms

Future Directions

Biomass-Derived Fuel Processing

- Explore operating windows for reforming of biogas within ceramic microchannel reactor.
- Extend hybrid CFD/chemical-kinetics modeling to examine effects of fuel-processing strategies on heat-exchanger effectiveness and fuel-reformate composition and quality.

System Modeling

- Quantify efficiency of SOFC operation on biogas under the different reforming conditions that may be utilized.
- Examine benefits of integrated unit processes enabled by utilization of the ceramic microchannel reactor.

System Control

- Implement explicit form for Model Predictive Control for use in biogas-reforming system.
- Extend model-predictive control strategy to reactive heat exchanger.

*Congressionally directed project

Technical Targets

Dynalene FC is expected to help the fuel cell industry achieve their durability and cost targets to some degree. First of all, the coolant itself is being designed to have a life of 5,000 hrs. It is also expected to have excellent compatibility with the system materials and inhibit corrosion in the coolant loop. This will help in extending the durability of the fuel cell system components such as the pump, the radiator, valves, seals/gaskets and any other components coming in contact with the coolant. The coolant is also designed to work at -40°C, which will assist both transportation and stationary fuel cells to quickly warm up during cold starts.

The cost target for the coolant (in plant-scale production) is about \$10/gallon, which is very close to the retail price of current automotive coolants. This coolant will also eliminate the deionizing filter and other hardware associated with it (i.e. fittings, valves). It is also being designed to work with cheaper, lighter and thermally efficient components such as aluminum radiators (instead of stainless steel) and brass heat exchangers.

Accomplishments

Dynalene FC has been demonstrated by field testing to maintain a very low electrical conductivity and stay stable over several years. This was possible due to the addition of a nanoparticle into the coolant. This project addresses the optimization and scale up of this nanoparticle ingredient. The main accomplishments in this project so far are the design and set up of 10 L, 20 L and 100 L reactor vessels, and optimization of the production of nanoparticles in the 10 L scale. Optimization in the 100 L scale is continuing now and it is expected to be finished by the project end date (August 31, 2011). Other accomplishments include the development and optimization of the filtration process for the nanoparticles and quality control procedures.

Introduction

This project addresses the goals of the Fuel Cell Technologies Program of the DOE to have a better thermal management system for fuel cells. Proper thermal management is crucial to the reliable and safe operation of fuel cells. A coolant with excellent thermophysical properties, non-toxicity, and low electrical conductivity is desired for this application.

Dynalene Inc. has developed and patented a fuel cell coolant with the help of DOE Small Business Innovation Research Phase I and Phase II funding (Project # DE-FG02-

Fiscal Year (FY) 2011 Objectives

The overall objective of this project is to optimize and scale up the process to make Dynalene FC fuel cell coolant with a great deal of reproducibility. Following are some specific objectives that would help to reach the overall goal of the project:

- Demonstrate the production of one key ingredient of the coolant (a nanoparticle) in 10 L, 20 L and 100 L batches in a pilot-scale operation and study the effect of various process parameters on the size and charge density of the particles.
- Produce the nanoparticles necessary for the fuel cell coolant, Dynalene FC, in a very consistent manner (i.e., particle size, charge density and yield).
- Optimize the filtration process for the nanoparticles to minimize the cleaning time for different scales of operation.

Technical Barriers

This project addresses the following technical barriers from the Fuel Cells section (3.4.4) of the Fuel Cell Technologies Program Multi-Year Research, Development and Demonstration Plan:

- (B) Durability
- (C) Cost

04ER83884). However, this coolant can only be produced in lab scale (500 ml to 2 L) due to problems in optimization and scale up of a nanoparticle ingredient. This project will optimize the nanoparticle production process in 10 L, 20 L and 100 L reactors, optimize the filtration process, and develop a high throughput production method for the final coolant formulation.

Approach

Before this project, Dynalene researchers were producing the nanoparticles ingredients used in the fuel cell coolant in 100 ml, 500 ml and 2 L reactors. At 100 ml scale, the nanoparticles were produced using magnetic stirring and the heating was provided by a constant temperature bath. At the 500 ml scale, the stirring mechanism was changed to a mechanical stirrer with impellers, while the heating mechanism was still through a constant temperature bath. At the 2 L scale, the stirring was through a mechanical stirrer whereas the heating was accomplished by pumping hot water through the jacket of the reactor. In this project (for 10 L and 100 L reactors), mechanical mixers with multiple impellers and heating systems using the jacket of the reactor will be used. Mixing/stirring mechanism as well as the heating method impacts the particle size, charge density and the yield of the reaction. Therefore, an understanding of the influence of these parameters is very essential to obtain the nanoparticles with reproducible properties. Dynalene and Lehigh University have partnered to develop the scale up criteria needed to go from a 2 L scale to a 10 or 20 or 100 L scale. The two types of emulsion polymerization methods used in this project to make the nanoparticles are batch and shot-growth methods.

Results

The batch style polymerization recipe at the 10 L scale did not produce the desired results (in terms of particle size and charge density). This method was abandoned in favor of optimizing the shot growth procedure which showed promise in the 2 L scale.

Shot growth polymerization is when a large portion of the reaction components are added to the reactor at the beginning of the reaction, the reaction is initiated, and the reaction is allowed to progress to 80 to 90% completion before a “shot” of co-monomers is added quickly to the reactor. This approach gives an added level of control to the reaction because the ratio of co-monomers in the shot has a large effect on the final particles.

The shot growth method has benefits over the batch method. The first is the large number of variables that can be altered to achieve the desired result. The following is a list of those parameters:

- Ratio of co-monomers
- Concentration of co-monomers
- Timing of shot

- Speed of shot
- Use of dip tube for shot addition
- Pre-emulsion of shot components

The shot growth method also has the benefit of a much higher solids concentration than the batch method. This higher concentration gives a much more efficient and cost-effective synthesis due to the increase in yield over the batch recipe. The optimum co-monomer concentrations and their ratio were determined at the 2 L scale and were left constant for the 10 L experiments. Experiments were also carried out to determine the correct timing of the shot, which was found to be between 2.5 and 3.0 hours after initiation of the reaction. All subsequent experiments were run with this timing.

Impeller position and the stirring speed were optimized next. Several reactions were run with the multi-impeller set-up in combination with the slower stirring speed. The scanning electron microscope (SEM) picture (Figure 1) showed a uniform, consistent particle size in the 200-250 nm range. Surface charge density was also within the expected range of 500-1,000 $\mu\text{eq/g}$ (Table 1).

Optimization of cationic nanoparticle synthesis at 10 L scale was completed and the initial testing with the 100 L reactor begun. The testing started with dyed oil and water in which the oil represents the styrene. It is necessary to decrease the stirring speed when scaling up because the tip speed on the larger impellers is much greater at the same rotational speed. Too much shear creates unwanted

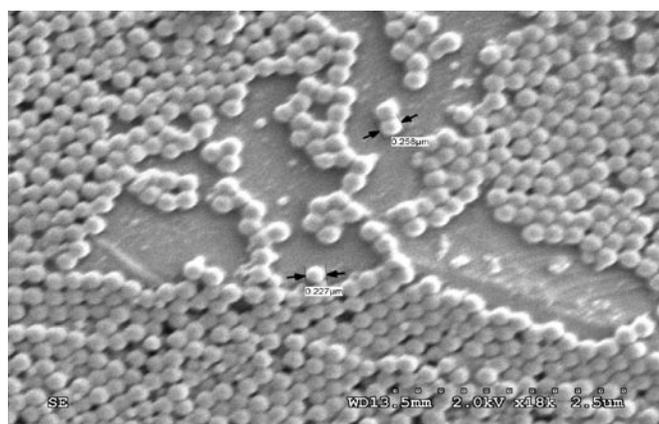

FIGURE 1. SEM Picture of the Cationic Particles Produced in 10 L Scale

TABLE 1. 10 L Scale Cationic Particle Experiments with Optimized Parameters

Experiment	Reaction type	Particle Size (nm)	Surface Charge Density ($\mu\text{eq/g}$)
JWM-0002-07	10 L shot growth	230	500-1,000
JWM-0002-10	10 L shot growth	225	500-1,000
JWM-0002-12	10 L shot growth	230	500-1,000
JWM-0002-14	10 L shot growth	235	500-1,000

results in the final latex, mostly coagulum and non-uniform particle distribution. The impellers were initially set up with geometric similarity to the final placement at the 10 L scale.

Testing was conducted at room temperature first to determine the minimum mixing speed to mix efficiently without high shear. It was not possible to achieve complete mixing at a speed low enough to eliminate vortexing at the initial reaction volume. It was necessary to either add another impeller or reduce the volume in the reactor to increase mixing efficiency. It was determined to decrease the reaction volume to better fit the reactor with the current number of impellers. The impeller spacing was altered to work with the decreased reaction volume.

Testing was resumed at room temperature with the new impeller placement and decreased volume concentration. It was possible with the new set-up to achieve complete mixing without the formation of a vortex. Photographs of the dyed oil/water mixing study can be seen in Figure 2.

Testing of the heating system also was carried out in conjunction with the mixing study. This testing included measuring the efficiency of the heating system while studying the effect of temperature on mixing efficiency. It was discovered at this time that the current heating system

configuration was not able to heat the full volume of the 100 L reactor to the reaction temperature. A larger pump was installed in the heating system to increase the flow rate of the heating water through the reactor jacket. Testing was resumed and the reactor achieved the reaction temperature within two hours.

The impeller configuration and stirring speed were optimized at the 100 L scale with dyed oil and water at the initial reaction volume. Further testing is currently being done to optimize the stirring conditions with the addition of the shot to the reactor.

Conclusions and Future Directions

Dynalene has set up all the reactors for the nanoparticle production. After some preliminary testing, the 10 L reactor was used for the synthesis of the nanoparticles. The scale up criteria developed in collaboration with Lehigh University was verified. It was determined that a shot-growth approach was better suited than a batch synthesis. Shot addition time and the process as well as the speed of the stirrer were optimized to obtain the right size and surface charge of the particles. Nanoparticle synthesis in the 10 L scale was repeated several times and the particle size

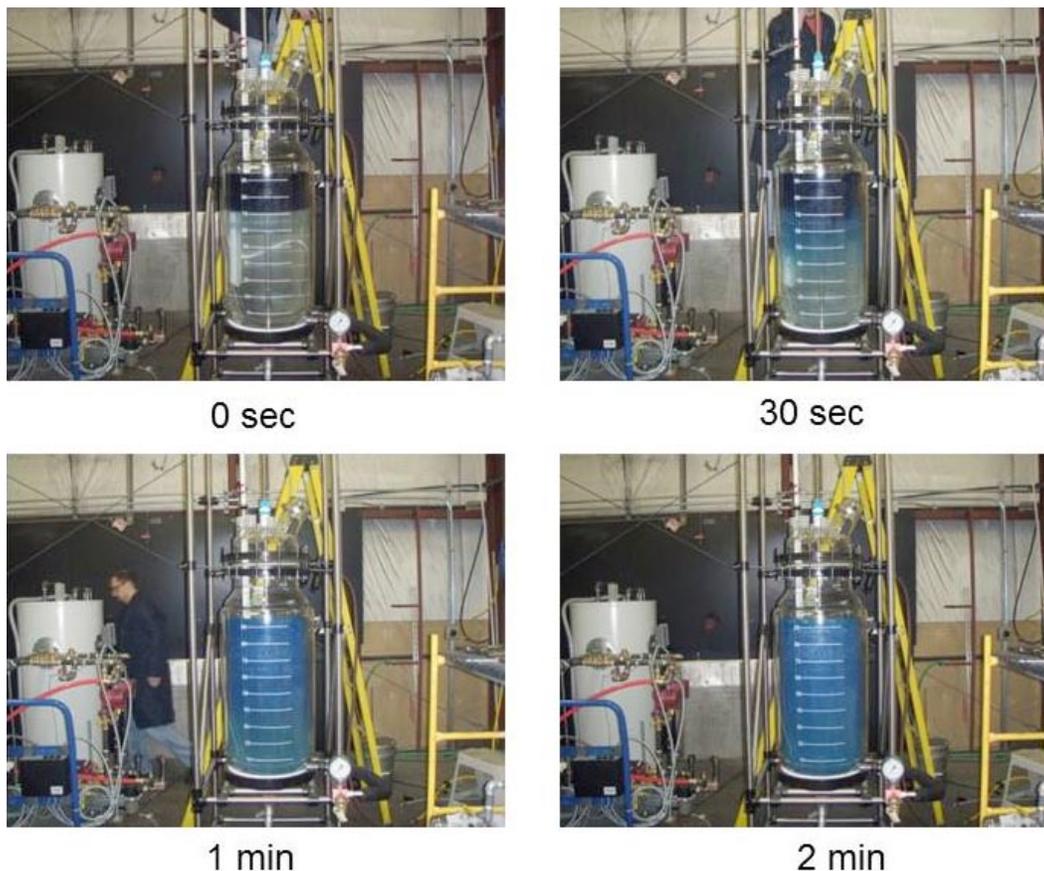

FIGURE 2. Oil/Water Study to Determine Mixing Parameters in the 100 L Glass Reactor

as well as the surface charge density was reproduced, thus making it a viable process for future commercial production. An oil/water study was conducted in the 100 L scale to optimize the stirrer position and the speed. In the future, nanoparticle synthesis will be performed at this scale, and filtration will be performed in 5 L scale to produce clean nanoparticles for subsequent production and testing of the fuel cell coolant.

Project Start Date: July 1, 2010

Project End Date: June 30, 2012

*Congressionally directed project

- (A) Durability
- (B) Cost
- (C) Performance

Technical Targets

This project is conducting fundamental studies to develop a new class of high-temperature PEM fuel cell materials capable of conducting protons at elevated temperature (180°C), multi-fuel reformer system, high power density lithium-air battery, and high energy yield bio-crop cost analysis and production model. If successful, insights gained from these studies will be applied toward the design and manufacturing of advanced membrane materials, lithium-air battery and multi-fuel reforming system that meet the following DOE 2015 targets:

- Cost: \$20/m² for high-temperature PEM membrane.
- Improved membrane conductivity and durability.
- Cost-effective multi-fuel reformer system.
- High power density lithium-air battery with simple control systems at a reduced cost.
- High energy yield agriculture bio-crop cost analysis and production model.

FY 2011 Accomplishments

- Polybenzimidazole (PBI)-polyamide (PA) membrane with good mechanical integrity has been successfully fabricated and a reproducible fabrication method has been developed where molecular mass was a function of the mechanical stirrer torque. Fabricated PBI-PA membranes with high molecular mass and good mechanical integrity. Sulfonic acid polyhedral oligomeric silsesquioxane (POSS) nanoadditive (S-POSS) was already prepared on the 100-g scale. Phosphonic acid POSS (P-POSS) nanoadditive was also prepared on the 2-g scale.
- The developed high-temperature PBI-PA-based PEM membrane is capable of meeting proton conducting membrane materials requirement at a cost of 60% below the DOE targets for 2015. Fabrication of a membrane electrode assembly (MEA) (Pt/C-membrane-Pt/C) is currently underway subject to exact real-world fuel cell operating conditions.
- Optimized design of a multi-fuel catalytic flat plate steam reformer with combustion and reforming catalyst separated by solid flat plate boundary is completed based on a computational fluid dynamics (CFD) model simulation results. Based on the optimized design, a first generation fuel reformer prototype has been fabricated. Currently we are testing the multi-fuel reformer prototype to generate data to benchmark the performance.

Fiscal Year (FY) 2011 Objectives

- Research, develop and fabricate an improved high-temperature proton exchange membrane (PEM) fuel cell membrane capable of low-temperature starts (<100°C) with enhanced performance.
- Research, develop and fabricate a 5 kWe novel catalytic flat plate steam reforming process for extracting hydrogen from multi-fuels and integrate with high-temperature PEM fuel cell systems.
- Research and develop improved oxygen permeable membranes for high power density lithium air battery with simple control systems and reduced cost.
- Research and develop a novel high energy yield agriculture bio-crop (Miscanthus) suitable for reformat fuel/alternative fuel with minimum impact on human food chain.
- Extend math and science alternative energy educator program to include bio-energy and power.

Technical Barriers

This project addresses the following technical barriers from the Fuel Cells section of the Fuel Cell Technologies Program Multi-Year Research, Development and Demonstration Plan:

- Fabricated numerous button cell lithium-air battery prototypes to evaluate performance of various components. Characterized various battery properties including charge-discharge cycle testing, open-circuit voltage (OCV), and total charge-discharge capacity. Characterized electrolyte conductivity and electrode polarization resistance for improved performance of lithium-air battery. Fabricated an oxygen permeable membrane for lithium-air battery cathode with an oxygen permeability of 10^4 to 4×10^3 barrer and a moisture permeability of 1 to 5 barrer.
- Two primary methods have been demonstrated at scale for the production of ethanol from cellulosic biomass crops, *Miscanthus giganteus* (MG) as a feedstock for ethanol: (i) *giganteus* hydrolysis and fermentation; and (ii) gasification and microbial reaction. The main output of this task will be a comprehensive cost- and energy-balance for the production of MG and its conversion to ethanol by each of these methods. A spreadsheet model has been developed that enables the practitioner/ bio-crop producer to evaluate the role of key agronomic factors on MG production costs and net energy balance relative to those of alternative energy crops.
- Learning objectives for the alternative energy educator program (workshop) are being developed. The development of the instructional design document including instructional strategy methodologies has begun. The identification and/or development of learning activities that will engage the participants in the learning process are also in process.

Introduction

Low-temperature PEM fuel cells operate at 80°C and requires nearly pure (99.9999%) hydrogen [1]. However, the lack of a hydrogen refueling infrastructure has been a significant barrier for commercialization, especially for large volume markets such as commercial transport, military silent watch, residential homes, telecommunications, and waste fuel processing to power applications [1]. To leverage the significant commercial potential of this emerging technology globally, the solution has always been considered as on-board fuel processing (or fuel reforming) for hydrogen extraction from locally available logistics fuels such as propane, diesel, JP8 fuel (for military), natural gas, methanol, ethanol, synthetic, and bio-renewable fuels [1]. However, the challenge has been the development of an on-board hydrogen fuel reforming “system” that is cost effective, compact, and commercially viable. Since the production of pure hydrogen required additional equipments and cost for fuel reforming, low-temperature PEM fuel cells are not a viable option for use with logistic fuels for large scale global fuel cell markets [1]. As such the primary technical and commercial challenge is the development of a cost-effective fuel cell electric power generation system capable

of using locally available logistics fuels and applicable for small- and large-scale applications worldwide. Traditionally, the approach has been to focus on the development of fuel reforming technology for low-temperature PEM fuel cells, including the removal of fuel impurities [1]. Unfortunately, this approach results in excessive fuel reformer cost, larger reformer size and high complexity. Conversely, our solution is to focus on the development of a more robust “PEM fuel cell combined with fuel reforming system” that is more tolerant of fuel impurities which reduces not only the fuel reformer cost, complexity, and size, but also increases the overall system efficiency. Since a high-temperature PEM fuel cell operates at 160-180°C, it allows the use of non-pure hydrogen (2% CO mixed with hydrogen stream) as a fuel [2] while maintaining the cost and expanding the application flexibility benefits comparable to low-temperature PEM fuel cells. The expected outcomes include: 1) more efficient use of thermal energy or by-product heat as a combined heat and power application resulting in high system efficiency; 2) reduction of balance-of-plant (BOP) components for cooling, water management and purification resulting in reduced maintenance and simpler operations and controls; 3) when using reformed fuels rather than pure hydrogen, the result is increased tolerance to carbon monoxide (CO) which reduce the equipment and capital cost necessary to remove fuel impurities; and 4) will move this emerging technology closer to meeting DOE’s 2015 power density target of 100 W/L for fuel cells and reformed fuels.

In this project, using Michigan Molecular Institute’s (MMI’s) patented [3] nanoadditives-based high-temperature PBI-PPA membranes those are known to be thermally stable up to 200°C with superior proton conductivity, we plan to test the performance of a 25 cm² active area high temperature PEM fuel cell with up to 5% CO mixed reformat directly pumped from the reformer to the cell. At Kettering, we designed and built the multi-fuel reformer based on a rigorous CFD model simulation to use locally available logistic fuels/bio-fuels. Bio-fuels are planned to be extracted from a high energy yield agriculture bio-crop, MG, which is suitable for bio-fuel extraction without any impact on human food chain. For fuel cell energy storage purpose, we are developing and fabricating lithium-air battery with superior charge-discharge capacity. Finally, we intend to extend math and science alternative energy educator program to include the research results in bio-energy and power generation topics.

Approach

- Use patented novel polymer synthesis technology to prepare a high-temperature proton exchange polymeric media that has been designed primarily to have high proton exchange capability at elevated temperature.
- Using CFD model results, design and fabricate a 5 kW novel catalytic flat plate steam reforming system for extracting hydrogen from multi-fuels and integrate with high-temperature PEM fuel cell systems.

- Develop improved oxygen permeable polymer membranes for high power density lithium air battery and use it to design simple control systems at reduced cost.
- Develop and research of novel high energy yield agriculture bio-crop (Miscanthus) suitable for reformat fuel/alternative fuel with minimum impact on human food chain.

Results

In the past year, the main focus has been on S-POSS and P-POSS nanoadditive synthesis, and development of a method for synthesizing high molecular mass PBI in PPA, and casting mechanically robust membranes from the same PBI-PPA reaction solution. The S-POSS synthesis has been completed on a 100-g scale (one-step process, Figure 1a) and the P-POSS synthesis has been completed on a 2-g scale (three-step process, Figure 1b, in which the first two steps have been scaled up to 10-50 g). In order to achieve maximum molecular mass, and therefore the best film integrity upon casting for the PBI syntheses in PPA, it was determined that a precise 1:1 monomer ratio was of paramount importance, we found that 4% solids in PPA was optimum, and minor deviations in either direction caused a significant decrease in molecular mass (see Table 1). A digitally controlled stirrer was used and the torque (related to viscosity and molecular mass) was monitored during the reaction. After 24 hours at 205°C, a plateau torque value of 40 in-oz was measured. Regarding reaction vessels, plain wall resin kettles performed better than indented wall resin kettles (in which reagents were trapped in the

indentations). Films were cast by pouring the hot PPA mixture onto a substrate and spreading it using a doctor blade. Final membrane thickness can be controlled by adjusting the doctor blade setting (where the size of the gap determines the film thickness). Granite and glass substrates were evaluated and granite was selected because it had a flatter surface to ensure uniform film thickness, and appeared resistant to temperature and acid exposure. The membrane thickness in the final MEA should be able to be controlled by varying the time, temperature, and pressure during the MEA pressing process.

TABLE 1. *m*-PBI Inherent Viscosity as a Function Of Reaction Conditions

Reference	Time (hrs)	Temperature (°C)	% Solids in PPA	Inherent viscosity (dL/g)
805-13	168	205	6.52	1.597
805-18	96	205	6.18	0.866
815-1	24	205	3.75	1.585
815-4	72	205	4.00	2.419
815-9	48	205	4.00	2.247
815-12	48	205	3.99	1.779

During the past year, by taking into account the effect of channel length, inlet gas velocity and catalyst layer thickness for flat plate reformer system we optimized the multi-fuel reformer system with water-gas shift (WGS) reaction in order to build a flat plate reformer prototype for real world testing. Figure 2a represents the production of dry H₂ with WGS reaction and optimized reformer geometry for methane reforming. The reformer geometry is optimized based on the optimized channel height, inlet velocity and catalyst layer thickness. From Figure 2a we see that the production of dry hydrogen only went up by 2% (mole fraction of H₂ from 0.76 to 0.78) with the WGS reaction. It is due to the fact that no methane is available in the WGS zone to produce H₂. Figure 2b represents the production of dry CO with the WGS reaction and optimized reformer geometry. From Figure 2b we see that the amount of dry CO was reduced by more than 50% (mole fraction of CO went down from 0.158 to 0.072 on dry basis) with WGS reaction. Therefore, it is advantageous to include WGS reaction with the optimized fuel reformer geometry especially in order to get low CO-rich reformat H₂. We already built a flat plate fuel reformer based on this optimized simulation study and the real world testing is underway to evaluate the effect of different parametric conditions.

For the lithium-air battery, in the past year, the main focus has been on fluorinated hyperbranched polymer (HBP) synthesis for oxygen permeable membrane fabrication, cathode development, solid electrolyte development, cell fabrication, and cell characterization. The fluorinated HBP was synthesized using MMI's patented bimolecular non-linear polymerization technology and used

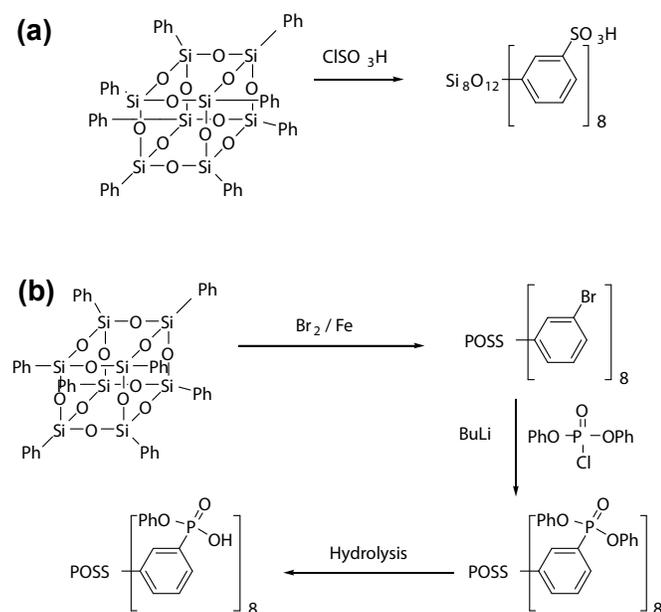

FIGURE 1. (a) Production of S-POSS Nanoadditive (b) Production of P-POSS Nanoadditive

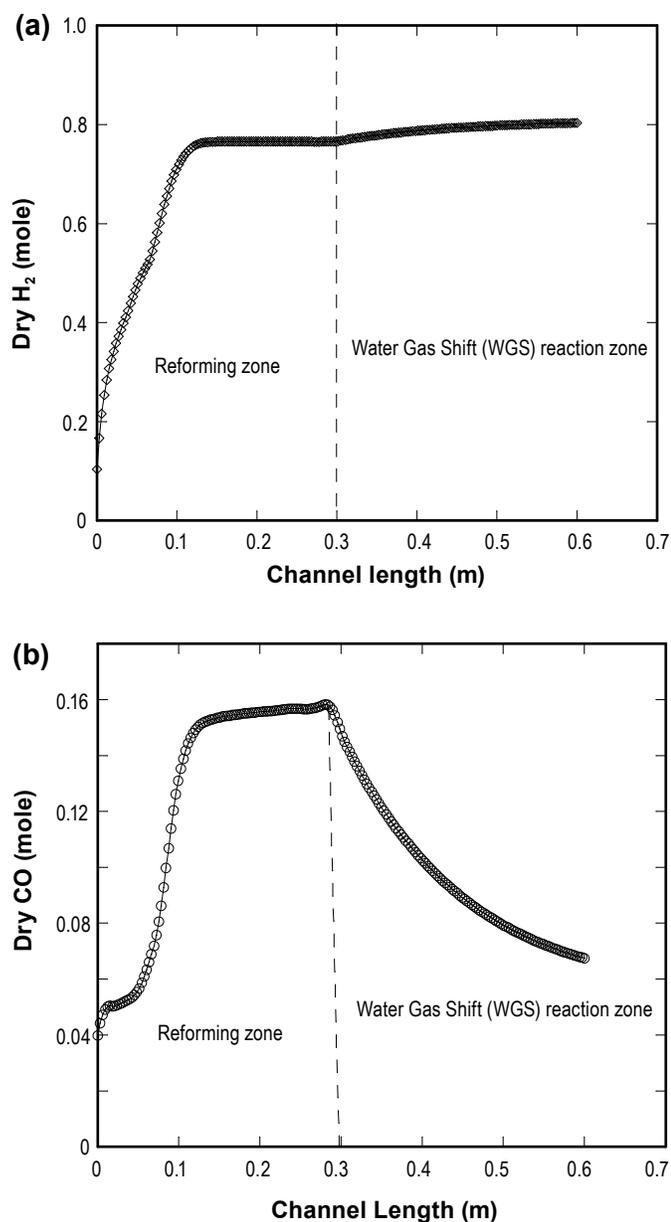

FIGURE 2. (a) Production of Dry H_2 with WGS and Optimized Reformer Geometry (b) Production of Dry CO with WGS and Optimized Reformer Geometry

in the oxygen selective membrane fabrication. A commercial porous PTFE/polypropylene (PP) support coated with the fluorinated HBP has been prepared. The evaluation for oxygen and moisture permeability is currently being carried out. Air cathodes for the lithium-air battery were based on nickel foam (current collector), carbon (electrical conductor), lithium aluminum germanium phosphate (LAGP)-based ion conductor, and PTFE (binder). The LAGP/C ratio was varied from 75/25 to 25/75 in order to obtain the best cell capacity and performance. A cobalt catalyst was explored which was found to enhance the cell capacity. The use of a solid ceramic electrolyte greatly

improves safety and durability of the cells, but requires the cells to operate at elevated temperature for best performance. In addition, the rigid ceramic electrolyte can suppress dendrite formation from the lithium anode during the charging process. A literature process was replicated as a starting point to develop an optimum battery. A three-layer electrolyte comprising a LAGP ceramic center sandwiched between two polymer electrolytes was used. A polymer electrolyte was used as a protective layer to prevent the direct contact of Li metal with the ceramic disc. In addition, the polymer layers also improve the contact between the electrolyte and both the anode and cathode. Several kinds of polyethylene oxide (PEO)-based polymer electrolyte layers were prepared. PC(Li₂O), PC(BN), and PC(SN) discs were obtained by ball mill mixing followed by pressing at elevated temperature. The three layer PC(BN)/LAGP/PC(Li₂O) electrolyte was obtained by lamination of the three layers at elevated temperature. The conductivities of these solid electrolytes were measured and shown in Figure 3a. Solid button cells were fabricated utilizing the Ni/C/LAGP/PTFE based cathode, the PC(Li₂O)/LAGP/PC(BN) solid electrolyte, and a lithium metal anode. The cells were tested under dry air using a 0.1 mA discharge current. The OCV of the cells were above 3.1 V, however, the cells did not show any discharge capacity at room temperature. When the cells were tested at elevated temperature (60-80°C) they did show some discharge capability even in the absence of any catalyst in the cathode. The cell capacity increased with an increase of the amount of carbon in the cathode. In addition, as expected, the specific cell capacity was greatly enhanced with the addition of a Co₃O₄ catalyst to the cathode (1,160 mAh/g C). Although the cells showed some promising properties, the maximum discharge current allowed was small. The internal resistance of the cells was very high at room temperature (>2,000 ohm) and decreased with an increase of temperature. However, the same or even higher internal resistance with a single layer polymer electrolyte compared to that of a three layer electrolyte suggests that interfaces, not the electrolyte itself, are the main factors for the high internal resistance and thus a low discharge current. A cell with a liquid electrolyte wetted interface between the solid electrolyte and the Li anode showed significantly improved cell capacity as shown in Figure 3b. To improve on the small discharge current, alternative polymer and gel type electrolytes are being explored. HBP materials based on organosilane and polyethylene glycol (PEG) are under development. Siloxanes are nonvolatile, nonflammable, highly resistant to oxidation, nontoxic, have a low T_g, and are environmentally benign. PEG is effective in solvating lithium salts and thus is lithium ion conducting. To further improve on the electrolyte, polar molecules are attached to the HBP periphery. For example, the reaction of tetrakis(dimethylsiloxy)silane with diacrylated PEG was carried out in toluene in the presence of platinum catalyst. A portion of the Si-H end groups (50-90%) are converted into polar groups such as cyclic carbonate, which can increase solvation and ion pair separation ability of the HBP.

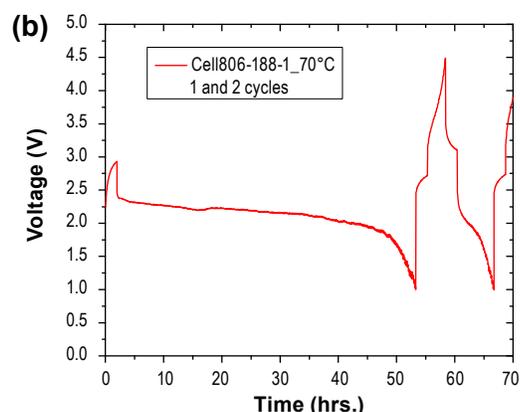

FIGURE 3. (a) Data of conductivity of the solid electrolyte components and three layer stacks. (b) The first two cycles (charge-discharge) of lithium-air battery prototype cell tested at 70°C.

In addition, it was expected that fast molecular motion of the hyperbranched side chains would contribute to fast ionic transport.

For high energy-yield bio-fuel agriculture crop MG production, during the past year, we developed a spreadsheet model for predicting the costs of production of MG relative to other energy crops (eg. switchgrass). Results of these studies are drawn together with the purpose of providing the U.S. Department of Energy with a convenient and flexible method of calculating production costs relative to alternative energy crops. The method is based on a standard, cost-accounting approach reported in earlier studies on MG production by Khanna et al. [4]. Using discount methodology [4], that analysis accounts for the outputs generated and the inputs required (cash flow) over the lifespan of the crop. The main result is a calculation of net present value, which is the total margin over the crop lifetime, converted into equivalent value in today's money. With that method, a breakeven price is calculated as the price in current dollars needed to offset all production costs over the lifetime of the crop discounted to current prices divided by the discounted value of successive crop yields:

$$\text{Breakeven price} = \frac{\sum_{i=0}^{i_{max}} C_i / (1+r)^i}{\sum_{i=0}^{i_{max}} \phi_i / (1+r)^i} \quad (1)$$

In this expression, i_{max} is the crop lifetime in years, ϕ_i is the yield per hectare in year i , r is the discount rate, and C_i is the cost of production per hectare in year i . Currently, we are performing detailed sample calculations to guide the user in building a spreadsheet model. Costs of production are split between one-time establishment costs in year one, and annual maintenance and harvesting operations in each subsequent year. Costs of production are further split among the primary unit operations of rhizome propagation, crop establishment, cultivation, harvesting, baling and storage, and delivery to a bio-energy plant.

Conclusions and Future Directions

From FY 2010 to the current date has resulted in a great knowledge expansion regarding manufacturing processes of new high-temperature PEM materials, lithium-air battery development and fabrication process, and multi-fuel reformer prototype development. We now understand the manufacturing process of new materials and the performance validation protocols in quantitative terms at least at the laboratory-based manufacturing stage. We have a good understanding of the polymer chemistry, thermodynamics and electro-kinetics. This information is critical to develop new high-temperature membrane materials for fuel cell applications where chemical treatment, polymer casting, and performance evaluations are of the utmost importance. Although the DOE deliverables of our project to date have been achieved, this year we intend to submit final project report after finishing the following attributes:

- Having developed a reliable method of membrane fabrication, PBI-PPA membranes carrying S-POSS or P-POSS at appropriate loadings will be prepared, compared with PBI-PA control membranes, and characterized for in-plane proton conductivity, tensile strength and elongation to break, phosphoric acid content (via titration), and morphology and domain structure. The best method of making MEAs to specifications suitable for utilization in fuel cell stacks will be developed. MEAs will be evaluated in stacks and also used to make through-plane conductivity measurements.
- Evaluate the multi-fuel reformer performance for different parametric conditions and further refinement of multi-fuel reformer will be performed if needed.
- Further refinements to the cathode formulation, electrolyte composition, solid electrolyte fabrication, and/or button cell fabrication will be made and the resultant batteries will be tested to insure that a reproducible system is obtained. Lithium-air batteries

will then be fabricated incorporating the fluorinated HBP-based membranes and tested under varying relative humidity conditions to determine how effective the membranes are towards enabling oxygen permeation while retarding moisture permeation. Prototype battery fabrication will require switching to a pouch type battery with non-ceramic electrolytes to achieve the desired voltage and power output.

- Develop a detailed cost- and energy-balance for miscanthus production.

Project Start Date: August 1, 2010

Project End Date: July 31, 2012

*Congressionally directed project

- Novel membranes, heterogeneous catalyst materials and structures will be developed and subsequently validated.

- Develop collaborative research projects with industries to improve the performance stability and long-term reliability of advanced fuel cells and other power generations systems.

Technical Barriers

This project addresses the following technical barriers from the Fuel Cells section of the Fuel Cell Technologies Program Multi-Year Research, Development and Demonstration Plan:

- (A) Durability
- (B) Cost
- (C) Performance

Technical Targets

The projects address technical aspects of stationary fuel cells and stationary fuel processors. DOE 2011 targets are as follows:

- Stationary proton exchange membrane fuel cell stack systems (5-250 kW) operating on reformat:
 - Cost: \$530/kWe
 - Durability: 40,000 hours
- Stationary fuel processors (equivalent to 5-250 kW) to generate hydrogen-containing fuel gas:
 - Cost: \$220 /kWe
 - Durability: 40,000 hours
 - H₂S content in product stream: <4 ppbv (dry)

FY 2011 Accomplishments

- The Center for Clean Energy Engineering has successfully developed 10 (year one) new industrially sponsored research, development and engineering projects in the field of clean and sustainable energy.
- These collaborative projects have leveraged DOE funds with industrial financial support to accelerate the development of advanced materials, cell and stack components, catalysts and fuel cleanup, and balance-of-plant sub-systems.
- The industrial projects support DOE through the development of reliable and cost-effective advanced clean and efficient fuel cell power generation systems.

Fiscal Year (FY) 2011 Objectives

- Develop an understanding of the degradation processes in advanced electrochemical energy conversion systems.
 - Advance fuel cell-based power generation systems architecture, including renewable hybridized energy conversion and storage.
 - Develop novel cell and stack structural and functional materials and validate their performance under the nominal and transient operational conditions for the evaluation of long-term bulk, interfacial and surface stability.
 - Gain fundamental understanding of chemical, mechanical, electrochemical and electrical processes related to:
 - Utilization of fuels ranging from bio-derived fuels to liquid petroleum to hydrogen.
 - The role of fuel impurities on degradation and processes for removal from feedstock.
 - Surface and interface phenomena related to surface adsorption, interfacial compound formation, and electron/ion generation and transport.
 - Electrodeics and electrochemistry.

Introduction

The overall scope of the energy systems and technology research and development initiative, at the UCONN Center for Clean Energy Engineering, will focus on the development and validation of the mechanistic understanding and subsequent creation of novel cost-effective materials to mitigate degradation processes. Through a unique collaborative program with industry we will solve technology gaps through joint industry/university projects. These relationships will accelerate the development and deployment of clean and efficient multi-fuel power generations systems.

The scope of the research projects will include identification and prioritization of the technology gaps and research needs along with the development of enabling technologies that meet the overall stack and balance-of-plant improvements from a durability, cost and performance perspective. Specifically, the performance stability and reliability of the power generation systems will be improved through the implementation of advanced materials and fabrication processes. Technical areas of interest, to be addressed by the industry/university collaborations will include: a) performance, stability and reliability of fuel cell systems, b) fuels, fuel processing and catalysis, c) advanced functional and structural materials, processes and systems, d) hydrogen storage and power management and e) renewable energy and resources.

Approach

The approach used for this project was to develop collaborative industry/university research projects aimed specifically at accelerating the development and deployment of clean and efficient multi-fuel power generation systems. Through a competitive process faculty developed relationships with industry that provided additional amounts of cash and in-kind support thus leveraging funding available through this project. By requiring a financial commitment from industry this methodology ensured that technology problems of commercialization relevance would be addressed.

During the first year industry collaborations have been executed with UTC Power, FuelCell Energy, UTC Research Center, nzymSys, NanoCell Systems, APSI, Oasys Water and W.R. Grace & Company. The project topics have addressed issues ranging from performance stability and reliability of fuel cell systems to fuels, fuel processing and catalysis and finally including advanced functional and structural materials, processes and systems.

Results

Modeling Resin Flow in Phosphoric Acid Fuel Cells (PAFCs) Gas Diffusion Layers (GDLs) – Project PI: Prof. Rajeswari Kasi, Industry Partner – UTC Power

UTC Power (UTCP) is interested in attaining stable graphitized GDLs that are used in PAFCs. GDLs coated

with catalyst (also called electrodes) are used to facilitate electrochemical reactions in PAFCs manufactured by UTCP. Resin flow into carbon fiber substrates blocks the open pore structure of the fibers impacting mass flow of various components to the catalyst layer. Furthermore, attaining stable GDLs is important to (1) increase the lifetime of GDLs, (2) efficiency of the power plant and (3) in lowering the cost of stationary and backup power. Thus in keeping with energy efficiency and renewable energy effort of DOE, the stability of GDLs is important for fuel cells to provide a clean, reliable, low-maintenance option for critical energy needs. So, UTCP is interested in generally understanding the morphology of these GDLs and overall resin distribution.

To address this issue, we have used optical imaging tools to qualitatively investigate the morphology of the carbon scaffold at every step of production of the GDLs. This allows us to establish where the carbonized resin is present in the final substrate. UTCP has supplied us with proprietary materials made via proprietary processing conditions. Using imaging as a tool, we have been able to identify two samples that show relatively uniform carbonized resin distribution as compared to other test variants. Our imaging studies (both surface and cross-sectional) have supplemented UTCP to understand the resin distribution and its impact on GDL morphology. In closing, this collaboration between UCONN and UTCP has resulted in improved understanding of morphology and material properties for GDLs in PAFCs, in keeping with the efforts of DOE. Furthermore, the knowledge gained from this study will be useful to implement in other examples of supported catalysts where optimal distribution of catalytic sites is essential for best catalytic performance.

Evaluation of Enzyme-Based Sulfur Removal Technology for Gas Cleanup – Project PI: Prof. Ashish Mhadshwar, Industrial Partner – nzymSys

A system designed for the enzymatic desulfurization of biogas has been tested at the lab scale. We have investigated the effect of several operational parameters such as enzyme concentration, biogas flow rate and enzyme boost on process performance. To date, our results show H₂S removal rates up to 100% without adverse effect on the methane and carbon dioxide concentration of the biogas. Long-term studies performed at high enzyme concentration (20 wt%) demonstrated formation of elemental sulfur, which could be recovered as a valuable product. As expected, the enzyme performance upon H₂S removal decreases when biogas retention time in the liquid enzyme is reduced. The H₂S breakthrough occurs at earlier times for higher biogas flow rates with a very steep change in concentration. Furthermore, fast enzyme saturation results upon increasing the gas flow rate. This could be overcome with enzyme replenishment, which indicates that this process could be potentially operated continuously for consistent removal of H₂S. This simple, reliable, non-conventional technology has various advantages to become one of the most efficient and economical desulfurization technologies and it could

be considered for larger scale applications. Future work will concentrate on evaluate the effect of reactor scale up and effect on mixing (stirring and packing material) on enzymatic desulfurization of biogas.

Waste to Energy: Biogas Cleanup (Desulfurization) for Energy Generation – Project PI: Prof. Steven Suib, Industry Partner – FuelCell Energy

This project involves the generation of getters (or adsorbents) and catalysts to react with sulfur species in feeds that would be used for fuel cells. The sulfur contaminants include hydrogen sulfide as well as various carbon sulfide materials. The major accomplishment of this work is that new adsorbents and catalyst materials have been made and are being tested for degradation of sulfur contaminants. Various materials have been prepared that are different from commercial desulfurization materials.

Testing of these systems with desulfurization studies clearly show that differences are observed for the various adsorbent materials. Breakthrough curves of various sulfur-containing species have been measured in this case of 0% relative humidity. In addition, studies have been done at various levels of relative humidity. Our results suggest that we have made materials that are more active than commercially available getters and adsorbents. Characterization studies are being done in order to optimize the performance of these materials.

Mechanistic Understanding of Matrix Stability in Molten Carbonate Fuel Cells – Project PI: Prof. Prabhakar Singh, Industry Partner – FuelCell Energy

Short-term and long-term electrically tested electrolyte matrix samples, obtained from our industrial partner FuelCell Energy, have been examined for morphological and structural changes to understand the coarsening and particle growth behavior. As received samples were examined at the matrix – anode and matrix – cathode interfaces. Samples were subsequently

washed in glacial acetic acid-acetic anhydride mixture to dissolve and remove the electrolyte. Obtained samples were further analyzed for the morphology of LiAlO_2 matrix material. It was observed that the matrix materials show different growth pattern in the anodic and the cathodic environments.

Two matrix samples tested for 240 and 6,984 hours were evaluated using X-ray diffraction, scanning electron microscopy (SEM), and Brunauer-Emmett-Teller techniques. As expected, the matrix samples containing electrolyte showed fully dense matrix structure (with localized porosity on the cathode side). The electrolyte was found susceptible to moisture as evidenced by localized overgrowth of hydrated crystals (Figure 1). Figure 2 shows the fractured cross-section of the matrix on the anode (AD-Side) and cathode (CD-side) tested for 240 h. The matrix morphology shows the presence of reinforcing fibers and core-shell structure. Very little change in the particle growth pattern is noted due to shorter exposure.

Figure 3 shows the cross-section of the electrolyte matrix electrically tested for 6,984 h. The matrix showed the features related to enforcement and core shell structure as observed earlier. Unlike the short-term tested sample, however, the long-term exposed sample showed growth in the particle size.

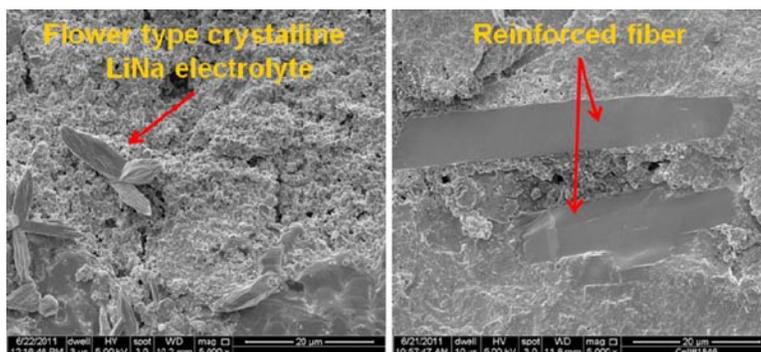

FIGURE 1. Field emission scanning electron microscope (FESEM) images of fracture cross-section of tested matrix. Flower type localized growth of Li-Na electrolyte and reinforced fibers in the matrix (right side).

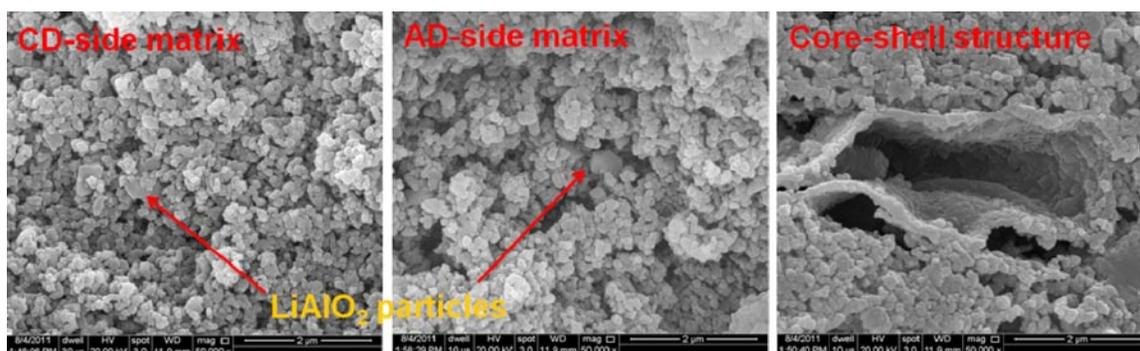

FIGURE 2. FESEM images of fracture cross-section of matrix tested for 240 h. Core shell structure shows the agglomeration of LiAlO_2 particles. Anode side matrix shows large crystallites.

It was also observed that the growth of particles in the anode side of the matrix was more pronounced than the particles present near the cathode electrode.

Evaluation of the Performance of Rapidly Quenched Yttria-Stabilized Zirconia (YSZ) Electrolytes in a Solid Oxide Fuel Cell (SOFC) and Its Comparison with Conventional SOFC Architecture – Project PI: Prof. Radenka Maric, Industrial Partner – NanoCell Systems

The microstructure and properties of rapidly quenched YSZ was investigated for 8 mol% YSZ (8-YSZ) powder manufactured by plasma sprayed using the solution precursor plasma spray technique, to produce metastable nanostructured powders using a pyrolytic melting or vaporization of an aerosol-solution precursor in a direct current-arc plasma. The preparation was done at the Center for Clean Energy Engineering at University of Connecticut in Storrs, Connecticut.

The material, plasma sprayed powder prepared in one processing step, was characterized for the microstructure of powder, thermal analysis and crystalline material structure at various temperatures and atmospheres. It showed stability of structure and composition in all the ranges of temperature and atmosphere the investigations were conducted. Conductivity tests for the plasma sprayed samples displayed slightly better conductivity than the most used YSZ powder, commercial available on market.

Optimization of Fluid Catalytic Cracking (FCC) Selectivity through Detailed Modeling of Catalyst Evaluation Experiments and the Contributions of Catalyst Components – Project PI: Prof. George Bollas, Industry Partner – W.R. Grace & Co.

An integrated model for Short Contact MicroActivity Testing (SCT-MAT) catalyst testing reactors (fixed bed) has been successfully developed. It couples a hydrodynamic model of a fixed bed reactor and a kinetic network that follows a lumping scheme. Moreover, it allows the comparison of predicted yields of the multicomponent

mixture from the reactor with experimental data provided by the industrial partner and acquired through a user interface developed in Microsoft Excel. The algorithm that simulates the fixed bed reactor solves a mathematical model derived from the continuity equation for multicomponent mixtures, using a more general approach than previous studies in the field, taking into account operational peculiarities of the SCT-MAT catalyst testing unit, as employed by the industrial partner. The kinetic network used involves parameters from lumping schemes. These parameters are obtained from an optimization algorithm developed to estimate reaction rates and constants, using the experimental data provided by the industrial partner. Thus, comparison between predicted and experimental yields of the different products of the catalyst testing reactors is available. More sophisticated hydrodynamic models have been developed for the Advanced Catalyst Evaluation (bubbling bed) and the Davison Circulating MicroActivity Riser catalyst testing reactors. Kinetic network models that provide a better insight of the reactions that take place in catalytic cracking reactors are being analyzed. In the near future, the effect of matrix type, zeolite content and diffusion characteristics, such as the crystal size, on the kinetic constants of the lumped kinetic network will be explored. In addition, a user-friendly interface has been developed in Microsoft Excel using visual basic serving two goals: (a) to facilitate the everyday use of the developed process models, and (b) to link the models with the extensive database provided by the industrial partner and ease usage of model during development.

These studies on reactor efficiency, lumped reaction kinetics and contributions of catalytic components will enhance productivity in catalyst research and development, will result in optimizing catalyst selectivity, and eventually lead to improving the overall refinery efficiency. Understanding the origins of coke deposits will help reducing the pollution from the FCC regenerator, while at the same time increasing FCC capacity by relaxing its carbon burning constraints. In that notion, this research project will aim to make FCC a cleaner process. Moreover,

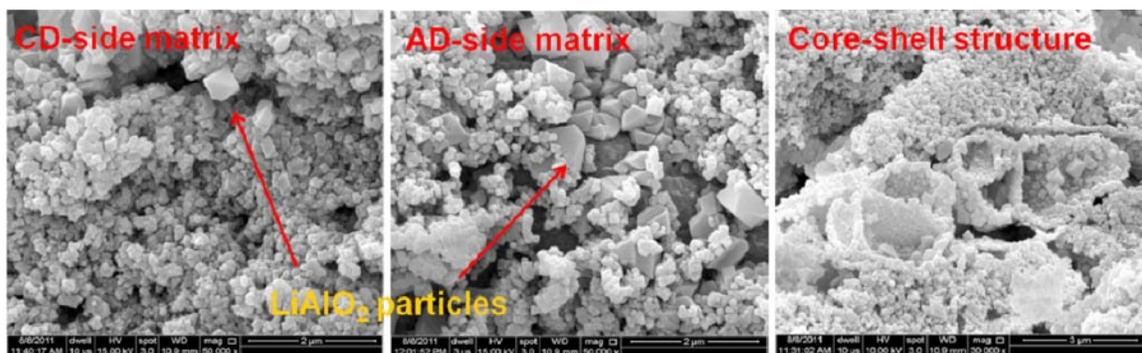

FIGURE 3. FESEM images of fracture cross-section of matrix tested for 6,984 h. LiAlO_2 particle coarsening is evident in cathode and anode side matrix. Core-shell structure shows the overgrowth of LiAlO_2 particles.

the fundamental knowledge acquired while decoupling reaction kinetics and catalyst deactivation and separation of the effects of zeolite and matrix on catalyst activity and selectivity, can be used to decouple gas and catalyst residence times to optimize biomass gasification and pyrolysis while decreasing secondary reactions.

Stannate-Based Semiconductor Nanocomposites for Solar Energy Utilization – Project PI: Prof. Puxian Gao, Industry Partner – UTC Research Center

First, continuous zinc hydroxystannate (ZHS) cube films have been achieved on both polycrystalline metallic substrates and transparent conductive substrates using hydrothermal synthesis method. As an example, via a fluidic chamber assisted hydrothermal method, continuous ZHS nanocube film have been fabricated on quartz or glass substrates, as shown in Figure 4. The temperature, pressure, and base concentration have been successfully used to control the cube coverage, crystallinity, size and film density.

Second, the structure evolution of ZHS cubes under various ambient annealing conditions has been extensively studied using a combination of structure, morphology and thermal analyses. Various in situ and ex situ microscopy and spectroscopy techniques have been utilized. The temperature windows of various phase transitions have been identified during the thermal decomposition of ZHS. Both temperature and ramping rate are found to be important parameters to control during the thermal processing of ZHS cube films, in order to achieve desired gradient functional composite cube films. The electronic and optical properties evolution in the ZHS cubes have been investigated. Using ZHS micro- or nano-cubes as template and precursor, gradient core-shell stannate-based composite cubes have been achieved after thermal processing. The optical and electronic properties of the gradient structures and corresponding photovoltaic cell performance are under investigation.

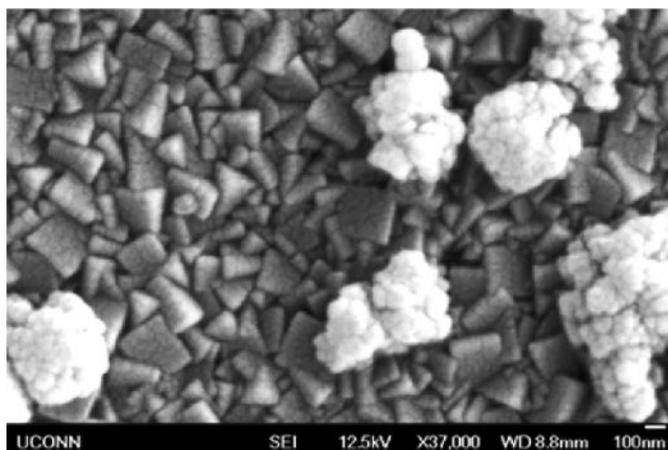

FIGURE 4. An SEM image for ZHS nano-cube films on quartz substrate synthesized by fluidic chamber assisted hydrothermal method.

Fuel Cell Electrode Microstructure: Nanoscale Stability and Efficiency – Project PI: Prof. Bryan Huey, Industrial Partner – UTC Power

Main results focus on two key aspects of fuel cell electrode microstructures.

First, atomic force microscopy (AFM) reveals profound differences in the catalytic nanoparticles in their raw state (Figure 5) and as a floc (upon Teflon[®] coating, Figure 6). The particle size is larger, Teflon[®] is occasionally drawn into fibers by the manufacturing process, and the <50 nm particles common in the raw material increases to >100 nm following Teflon[®] coating.

Second, upon phosphoric acid (PA) loading of the electrode, the Teflon[®] is occasionally found to separate from the underlying catalyst particles. This is clearly observed

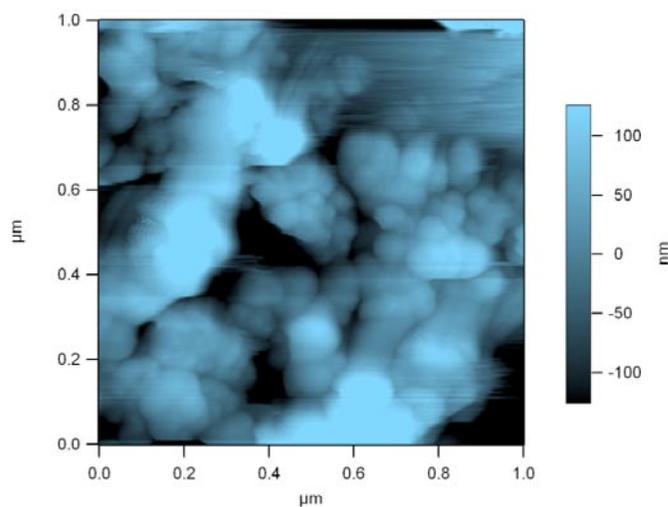

FIGURE 5. Pure Catalyst (10-100 nm particles)

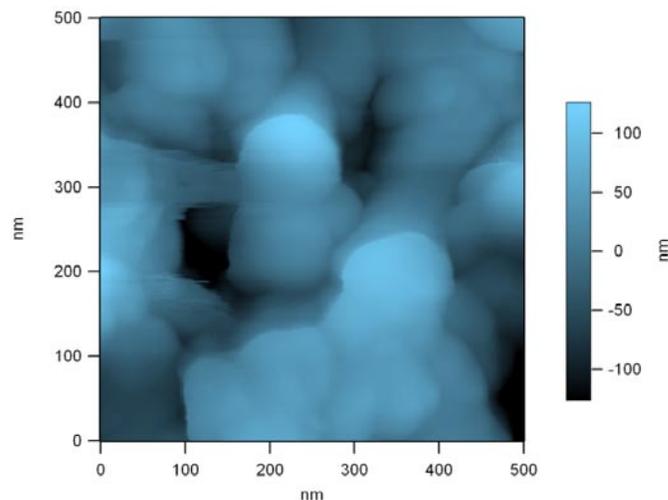

FIGURE 6. Teflon[®] Floc (>100 nm particles)

by AFM, both in topographic images where the Teflon[®] appears to have delaminated from the catalyst, as well as in simultaneous AFM phase contrast which reveals the local mechanical compliance. Notably, Teflon[®]/catalyst separation was only observed following PA loading, but never before PA exposure. It is unclear whether the PA loading procedure, or the simple act of Teflon[®] swelling upon PA exposure, causes such rupture.

Waste Heat Recovery using the Ammonia-Carbon Dioxide Osmotic Heat Engine – Project PI: Prof. Jeff McCutcheon, Industrial Partner – Oasys Water

Salinity gradient power technologies are quickly coming to the forefront of alternative approaches for producing electricity. One such technology being developed by Oasys Water is the Osmotic Heat Engine, a modified version of an engine cycle that uses a liquid phase intermediate to transfer energy to a turbine. Our work has been primarily focused on developing new membranes for this process. Our approach has two tasks.

First, we have developed a unique benchtop system for testing membranes under pertinent conditions in the osmotic heat engine. These systems are generally unavailable, and our system has shown that it can measure the power generating capacity of membranes (in watts/m²). The system has yielded positive results using a commercial membrane designed for *forward osmosis*, a sister technology to osmotic power. Figure 7 shows power densities approaching 4 watts/m² using 1M NaCl salt solutions. This is near the industry target (4 watts/m²) and this is the first time this commercial membrane has been successfully tested under this condition.

The second task has been to develop new membrane technology for pressure retarded osmosis (PRO) specifically.

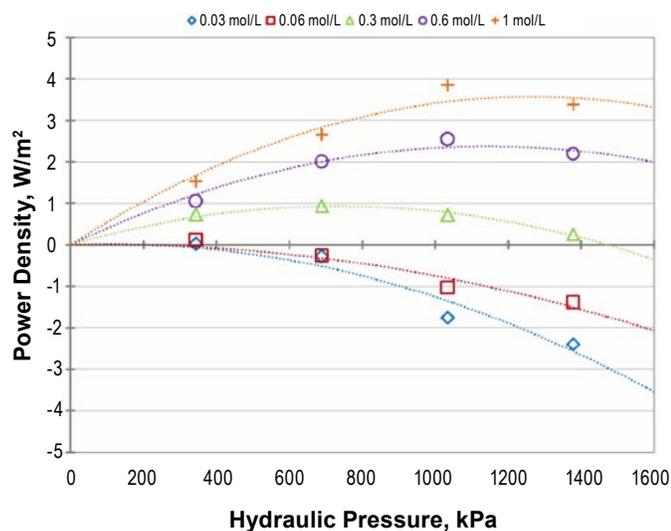

FIGURE 7. Power densities of commercial forward osmosis membrane using different salt concentrations over a range of hydraulic pressures.

We have found a way to modify current generation reverse osmosis (RO) membranes (which can operate under PRO conditions, but in the past have been very poor performers). We have modified RO membranes with polydopamine, a hydrophilic bio-inspired polymer to enhance osmotic flux. Our modifications have resulted in 8-12X increase in osmotic fluxes (Figure 8). Our next tasks will be to optimize this modification technique and test power density with the PRO system.

Fuel Reforming Catalysts for Efficient Energy Usage – Project PI: Prof. Steven Suib, Industry Partner – APSI

The major accomplishment of this project is that a new method has been discovered that allows formation of a fuel reforming catalyst with much less catalyst. This decreases cost and increases efficiency of the reforming of fuel. This method has been submitted as a patent application. The ability of this next generation catalyst to activate the reforming of hydrocarbons is under investigation and looks promising. This method involves the use of thin metal foils of various compositions that are immersed in solutions of precursors of other metals to produce metal alloy catalysts.

Characterization of these materials has involved surface composition, bulk composition, structure, electronic, and morphological properties. Various methods like atomic absorption, inductively coupled plasma, energy dispersive X-ray analysis, SEM, scanning Auger microscopy, X-ray powder diffraction, surface area, and pore size distribution methods are being used. Catalytic testing of the catalyst is being done with various fuels. Characterization of reactants,

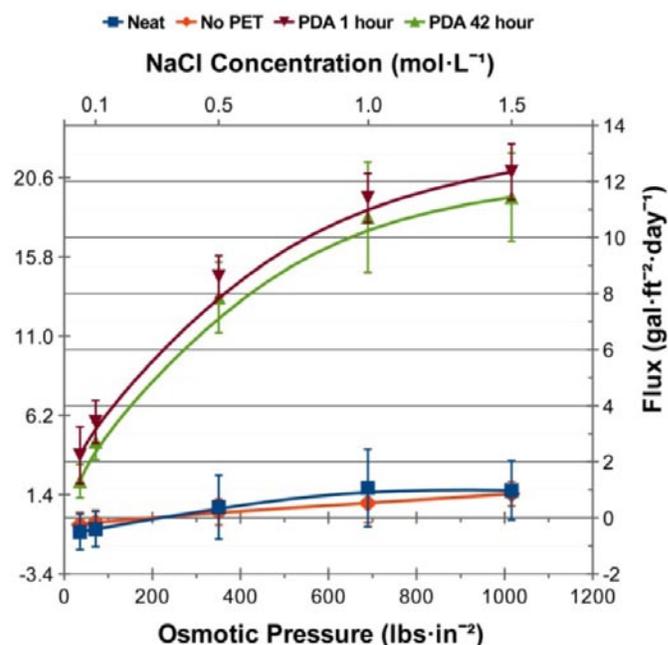

FIGURE 8. Osmotic fluxes of native and modified off the shelf reverse osmosis membrane from Dow Water and Process Solutions.

products and intermediates is done using gas chromatography, liquid chromatography, mass spectrometry, and temperature programmed desorption studies.

Conclusions and Future Directions

The 10 first-year projects are still ongoing and will continue through the balance of this calendar year. As appropriate, this list may be expanded to include a small number of additional relevant projects that address the technology gaps and barriers described. Future directions may include:

- Advanced functional and structural materials research and development will continue to address long-term surface, interface and bulk instabilities at engineered systems level. Research will continue in areas related to solid-liquid-gas interactions as they relate to surface corrosion, electrochemical poisoning, agglomeration and coarsening of porous aggregates, and catalytic degradation.
- UCONN and its partners will continue to develop advanced fuel cleanup and processing technologies to enable multi-fuel capabilities of advanced fuel cell systems. Cost-effective technologies for the removal of contaminants from gas phase will be developed and validated.
- Developed technologies will be transferred to industries to accelerate the development and deployment of advanced fuel cell systems.
- Research findings will be presented and published in technical meetings and peer reviewed journals. Intellectual property will be disclosed through invention disclosures and review by the university's center for science and technology commercialization.

FY 2011 Accomplishments

- Demonstrated SBTS mechanical performance over the required range of RRFCS fuel cell operating temperature, pressure and anode/cathode gas compositions.
- About 200 hrs of operating time at temperature with long-term operation planned in 2011 as part of the DOE Solid State Energy Conversion Alliance (SECA) program.
- Control and safety system hardware/software demonstrated up to powered stack operation.

Introduction

This project supported the mechanical/electrical build completion and mechanical commissioning of the SBTS located at the Stark State College (SSC) Fuel Cell Prototyping Center in North Canton, OH. As a result, SBTS is ready to support installation and powered operation of a RRFCS solid oxide fuel cell (SOFC) stack block in the second quarter of 2011. The SBTS will be used to evaluate the performance, reliability and durability of developmental fuel cell stacks at powers of about 20 kW. Fuel cell tubes that compose the SOFC stack are manufactured on the RRFCS PVL. The PVL is a fully automated production line for printing anode and cathode electrodes on fuel cell substrates, with the resulting assembly passed to a furnace for material sintering.

Approach

This project leverages earlier investments by the Ohio Department of Development (ODOD Grant TECH 08-053) through Ohio's Third Frontier and the Department of Energy (DOE Award No. DE-FE0000303, SECA), under which the SBTS mechanical build was completed. The subject work completed the mechanical/electrical build and completed the mechanical commissioning that included controls and safety system software checkout.

Results

Task 1 – Controls Software

Control functions were manually exercised to cover stack heat-up from room temperature to 900°C for stack reduction, transition from the stack reduction temperature to a lower temperature for stack electrical loading and stack cool down to ambient temperature. Startup burner control was established. The catalytic partial oxidation (CPOX) reactor light-off was proven with proper anode fuel gas composition provided to the stack. Operator actions were implemented into the automatic control system for SOFC

Objectives

- Complete the electrical/mechanical build of the RRFCS fuel cell Stack Block Test System (SBTS)
- Perform mechanical commissioning tests to assure SBTS readiness prior to fuel cell stack block install.

Technical Barriers

This project addresses the following technical barriers for the Fuel Cells section of the Fuel Cell Technologies Program Multi-Year Research, Development and Demonstration Plan:

- (A) Durability
- (C) Performance

Technical Targets

This project completes the mechanical and electrical build of a test apparatus (referred to as SBTS) that will allow RRFCS to test at fuel cell stack product size, full operating temperature and pressure, and with fuel cell inlet anode gas pre-processed from pipeline natural gas. Testing will prove the mechanical functionality of the SBTS prior to install of a fuel cell stack for electrical testing.

stack heat-up from ambient to about 750°C following startup burner light-off. Control functions associated with stack electrical operation (e.g., stack reduction and stack electrical loading) will be developed with existing manual control capabilities and then transferred into the automatic controls software as part of electrical commissioning under the 2011 SECA program.

In parallel with controls software development, the independent safety system software was exercised in response to trip signals with the SBTS responding properly during the emergency shutdown control sequence.

The user interface (HMI) to the control system was proven and enhanced as the various mechanical commissioning tests were completed under this contract. The HMI provides a satisfactory interface for SBTS operation and support for the future electrical commissioning tests.

Task 2 – Facility Electrical and Controls Wiring

All wiring tasks were completed in January 2011 with the installation of the high voltage (~1,100 V direct current) SOFC stack bus bar wires to the load controllers. Operational checks of the eight load controllers and calibration of associated current and voltage transducers were completed including communications to the control system and HMI. All instrumentation associated with SBTS was operated during mechanical commissioning except those associated with the electrical stack operation. The two items associated with cleaning of the oxygen supply tubing and cooling water connection to the load controllers were completed.

Task 3 – Commissioning

Stage 1 commissioning scope included the following:

- **Hardware and Configuration.** Verification of electrical continuity, component operation and instrument continuity through the control programmable logic controller and HMI. Verification of data storage to disk for each instrument.
- **Instrument Calibration.** Operation and calibration check of each flow meter.
- **Facility and Safety System.** Verify operability of natural gas; compressed air; and steam boiler delivery systems, system flare, exhaust pressure control system, and facility safety system/alarms. Exercise the CPOX reactor to demonstrate its functional performance and operating procedure.

System operation. Operation of the entire SBTS as a system from ambient temperature startup to hot stack operation at a condition ready for electrical power loading (Stage 2 commissioning performed in 2011 under the DOE SECA program). Demonstrate normal control system shutdown and safety system emergency shutdown. Perform control loop tuning to achieve acceptable

response and stability during normal operation and expected transients.

All of the planned Stage 1 commissioning tasks described by the previous bulleted items were completed by the middle of November, 2010. Progress was interrupted at the end of June due to damage of the high temperature insulation. Following its replacement, Stage 1 commissioning resumed and demonstrated the capability of SBTS to achieve the highest stack operating temperature of 900°C. During the interim period while the insulation was being replaced, the SBTS was able to operate for CPOX reactor control setup as well as establish the stack back pressure automatic control. Operation and automatic control of the startup burner was demonstrated. Functional performance and operation of the CPOX reactor was demonstrated with fuel delivered to the stack, albeit not electrically active for the Stage 1 program testing. All operations of the SBTS were demonstrated as needed to heat the stack from room temperature to 900°C for stack reduction and subsequent return to a lower stack temperature as required for stack electrical loading. Electrical stack tests will be accomplished outside of this project and part of the 2011 DOE SECA program.

Normal shutdown and safety/emergency shutdown response of the SBTS was demonstrated.

Controls operation was discussed in Task 1. During Task 3 commissioning, control loops were tuned to achieve acceptable response during SBTS operation.

For reference, Figures 1 and 2 show the completed SBTS test vessel and its installation for the Stage 1 project test.

Task 4 – Post-Operation Inspection

Following Task 3 test completion, inspection of the stack and hot zone components was made. In general, the internals were found to be in good condition and suitable

FIGURE 1. SBTS Vessel Assembly Prior to Install of the Outer Vessel Head

FIGURE 2. SBTS Ready for Commissioning Test

for use in the next test series subsequent to this contract. Carbon was observed in the burner inlet fuel line from CO use and will not be used in subsequent tests.

Conclusions and Future Directions

- Completion of the mechanical commissioning test proved the readiness of SBTS for install of a fuel cell stack and electrical commissioning test. Such testing is planned to begin in April of 2011.
- Control of the major SBTS subsystems was exercised and proven.
- The control and safety system software were exercised and shown ready for electrical commissioning test.
- The SBTS will be used in 2011 by RRFCS to obtain further performance and durability data for the RRFCS solid oxide fuel cell stack block which is the repeat unit for power generation at 1-MW scale.

VI. MANUFACTURING R&D

VI.0 Manufacturing R&D Sub-Program Overview

The Manufacturing R&D sub-program supports research and development needed to reduce the cost of manufacturing hydrogen and fuel cell systems and components. The manufacturing research and development (R&D) effort will enable the mass production of components (in parallel with technology development) and will foster a strong domestic supplier base. Activities will address the challenges of moving today's laboratory-produced technologies to high-volume, pre-commercial manufacturing to drive down the cost of hydrogen and fuel cell systems. This sub-program focuses on the manufacture of components and systems that will be needed in the early stages of commercialization. Research investments are focused on reducing the cost of components currently used (or planned for use) in existing technologies, as well as reducing the cycle times of the processes being developed. Progress toward goals is measured in terms of reductions in the cost of producing fuel cells, increased manufacturing processing rates, and growth of manufacturing capacity.

In Fiscal Year (FY) 2011, manufacturing projects continued in the following areas: novel electrode deposition processes for membrane electrode assembly (MEA) fabrication, high-volume fuel cell leak-test processes, novel assembly processes for low cost MEAs, gas diffusion layer cost reductions, flow field plate manufacturing variability and its impact on performance, and fabrication technologies for high-pressure composite storage tanks.

Goal

Research and develop innovative technologies and processes that reduce the cost of manufacturing fuel cells and related systems—providing critical support to industry and helping to spur the growth of a strong domestic supplier base.

Objectives¹

Currently, the sub-program is focused on technologies and processes for manufacturing polymer electrolyte membrane (PEM) fuel cells and tanks for high-pressure hydrogen storage.

Key objectives for fuel cell manufacturing include:

- By 2012, develop continuous in-line measurement for MEA fabrication.
- By 2013, reduce the cost of manufacturing MEAs by 25%, relative to 2008 baseline of \$63/kW_e (at 1,000 units/year).
- By 2015, reduce the cost of PEM fuel cell stack assembly and testing by 50%, relative to the 2008 baseline of \$0.84/kW_e (at 1,000 units/year).
- By 2017, develop improved fabrication and assembly processes for polymer electrolyte membranes that will enable an automotive fuel cell system cost of \$30/kW (projected to high-volume).

Cost targets for hydrogen storage tanks are currently being re-evaluated.

FY 2011 Technology Status

Presently, fuel cell systems are fabricated in small quantities. The cost of 5-kW, low-temperature PEM fuel cell systems for stationary applications is projected to be ~\$3,100/kW_{net} at a volume of 1,000 systems per year.² There were almost 2,000 stationary fuel cell systems shipped by North American manufacturers in 2010.³ For automotive applications using today's technology, the cost of an 80-kW PEM fuel cell system is projected to be \$49/kW for high-volume manufacturing (500,000 systems/year) and about \$220/kW at manufacturing

¹ Note: Targets and milestones are under revision; therefore, individual progress reports may reference prior targets.

² James, B. D., et al., "Low Temperature PEM Stationary Fuel Cell System Cost Analysis: Preliminary Results", NREL Subcontract Report, Subcontract number AGB-0-40628-01, May 2011.

³ *2010 Fuel Cell Technologies Market Report*, U.S. Department of Energy, June 2011. www1.eere.energy.gov/hydrogenandfuelcells/pdfs/2010_market_report.pdf.

volumes of 1,000 systems/year.⁴ The projected high-volume cost includes labor, materials, and related expenditures, but does not account for manufacturing R&D investment.

FY 2011 Accomplishments

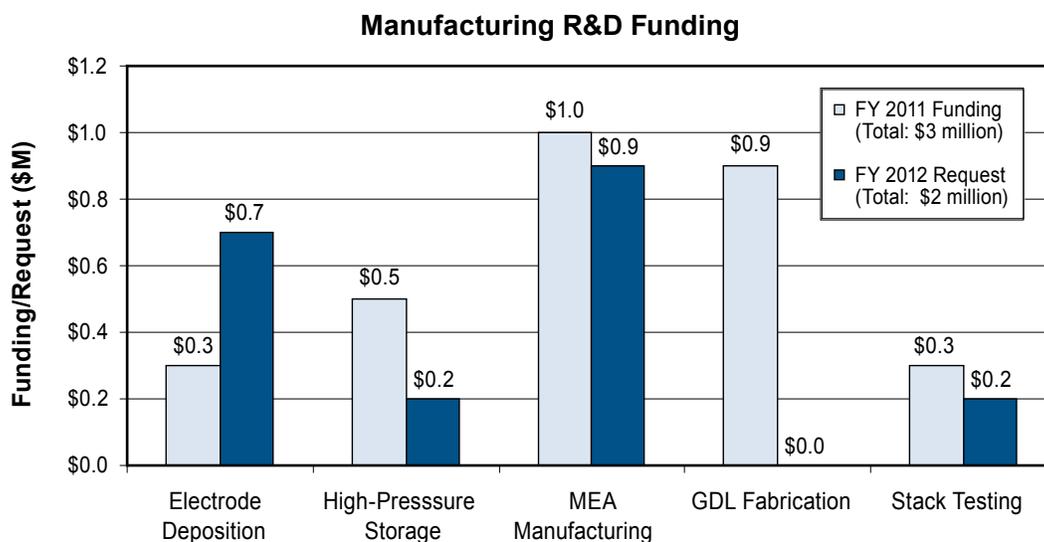

FY 2011 saw a number of advancements in the manufacture of fuel cells and storage systems, including:

- **Gas Diffusion Layer (GDL) Fabrication:** Ballard improved thickness and basis-weight uniformity of GDLs by adding mass flow meters to the “Many-at-a-Time” coating equipment, resulting in GDL cost reduction of over 60% since 2008, while increasing manufacturing capacity nearly four-fold.
- **Electrode Deposition:** W.L. Gore reduced membrane thickness, eliminated membrane backers, reduced scrap with better coating process, and eliminated finishing operations such as electrode and membrane edge trim. Gore previously demonstrated, using their cost model, that a new three-layer MEA process has the potential to reduce MEA cost by 25%.
- **High-Pressure Storage:** Quantum saved 17.4 kg of composite from the baseline (all fiber wound) vessel (23% savings).
- **MEA Manufacturing:** BASF reduced ink preparation time and the number of coating applications by >50%, and improved fuel cell performance by 20 mV over the baseline of 0.67 V at 0.2 A/cm². BASF also demonstrated a microporous layer on a production coater with full-width cloth.
- **Component and Stack Measurement:** The National Renewable Energy Laboratory demonstrated the ability to detect defects ≥ 6.25 mm² (e.g., pinholes, electrical shorts, and electrode thickness variations) and catalyst loading variations $\geq 10\%$ (at nominal 0.45 mg Pt/cm²) in MEAs using their internal resistance/direct current diagnostic.
- **Bipolar Plate Flow Field Uniformity:** Using their non-contact sensor apparatus for vertical and lateral measurement of flow field dimensions, the National Institute for Science and Technology showed that there was very little accuracy degradation as the scan rate was increased from 30 mm/s to 500 mm/s—allowing high-speed, fully-automated inspection.
- **Hydrogen and Fuel Cells Manufacturing R&D Workshop:** In August 2011, the National Renewable Energy Laboratory and DOE hosted a workshop to identify strategies and R&D needs for lowering the cost of manufacturing hydrogen production, delivery, and storage systems and fuel cell systems and components. The input from the workshop will be used to identify key barriers and needs for future Program activities as well as funding opportunities.

Budget

The President’s FY 2012 budget request for the Fuel Cell Technologies Program includes \$2 million for Manufacturing R&D. The FY 2011 appropriation for Manufacturing R&D was \$3 million.

⁴James, B.D., et al., “Manufacturing Cost Analysis of Fuel Cell Systems,” 2011DOE Hydrogen and Fuel Cells Program Annual Merit Review Proceedings, May 2011, www.hydrogen.energy.gov/pdfs/review11/fc018_james_2011_o.pdf, May 2011.

FY 2012 Plans

In FY 2012, activities in the Manufacturing R&D sub-program will: scale up production of low-cost MEAs; update the cost model of hydrogen pressure vessels to include the consideration of lower-performance carbon fiber; demonstrate a 2x reduction in the cost of MEAs by reducing labor involved in ink preparation and reducing the number of coating applications; and further develop the National Renewable Energy Laboratory's continuous in-line measurement of MEA fabrication.

Participants at the Hydrogen/Fuel Cell Manufacturing Workshop suggested a number of follow-on activities for DOE, including:

1. Hosting a meeting of manufacturers to initiate efforts to:
 - Establish a consensus on standard specifications for hydrogen and fuel cell systems and components.
 - Facilitate leveraging the buying power of multiple customers to reduce costs.
 - Facilitate development and expansion of the supply chain.
2. As an output of the first meeting, defining sub-groups to discuss and make plans to address (if possible) individual issues. Each sub-group can involve different supply chain vendors as necessary for their tasks/issues.
3. Hosting a meeting in which the sub-groups report back to the full working group for prioritization, decisions, etc.

Project Start Date: July 16, 2007

Project End Date: Project continuation and direction determined annually by DOE

- Use established models to predict the effects of local variations in MEA component properties, and integrate modeling of the operational and design characteristics of diagnostic techniques into the design and configuration of in-line measurement systems.

These objectives have strong support from our industry partners. Our specific development activities have been and will continue to be fully informed by direct input from industry. As new technologies emerge and as the needs of the industry change, the directions of this project will be adjusted. Additionally, in support of DOE's expanded scope, we have initiated activities to understand quality control needs for high-temperature fuel cell production and assess relevant inspection technologies.

Technical Barriers

This project addresses the following technical barriers, from the Manufacturing section (3.5) of the Hydrogen, Fuel Cells and Infrastructure Technologies Program's Multi-Year Research, Development and Demonstration Plan:

- (A) Lack of High-Volume Membrane Electrode Assembly (MEA) Processes
- (F) Low Levels of Quality Control and Inflexible Processes.

Contribution to Achievement of DOE Manufacturing Milestones

This project contributes to the achievement of the following DOE milestones, from the Manufacturing section (3.5) of the Hydrogen, Fuel Cells and Infrastructure Technologies Program Multi-Year Research, Development and Demonstration Plan:

- **Milestone 1:** Develop prototype sensors for quality control of MEA manufacturing (4Q, 2011).
- **Milestone 2:** Develop continuous in-line measurement for MEA fabrication (4Q, 2012).
- **Milestone 3:** Demonstrate sensors in pilot-scale applications for manufacturing MEAs (4Q, 2013).
- **Milestone 4:** Establish models to predict the effect of manufacturing variations on MEA performance (4Q, 2013).

FY 2011 Accomplishments

NREL accomplished the following in FY 2011:

- Developed continuous process prototype test-beds to enable initial validation of diagnostic techniques with moving substrates (simulating in-line measurement).

Fiscal Year (FY) 2011 Objectives

NREL and its collaborators are developing capabilities and acquiring knowledge for in-line quality control during manufacturing of polymer electrolyte membrane (PEM) fuel cells. We are focusing on membrane electrode assembly (MEA) components (membranes, coated electrodes, and gas diffusion media) in the transition to high-volume manufacturing methods. Our main tasks are to:

- Evaluate and develop in-line diagnostics for MEA component quality control and validate diagnostics in-line.
- Investigate the effects of MEA component manufacturing defects on MEA performance and durability to understand the required performance of diagnostic systems and contribute to the basis of knowledge available to functionally determine manufacturing tolerances for these materials.

- Demonstrated the operation of our infrared diagnostic system with direct current excitation (IR/DC) with moving gas diffusion media (GDM) and catalyst-coated membrane (CCM) sheet materials.
- Integrated LBNL modeling of the operational and design characteristics of the IR/DC technique into the design process for the in-line configuration of the diagnostic system.
- Developed a second infrared-based technique using reactive gas excitation to measure the spatial uniformity of electrodes on porous substrates, i.e., gas diffusion electrodes.
- Demonstrated the operation of our optical reflectometer diagnostic for areal membrane thickness imaging and defect identification with moving membrane sheet materials.
- Performed studies on the effects of MEA component defects, using single and segmented cells, including electrode thin spots, voids, and mud-cracks, and GDM polytetrafluoroethylene (PTFE) uniformity.
- Installed and commissioned a segmented cell system, using a 3M-developed design with 121 segments, to enable spatially resolved studies of the effects of as-manufactured defects in MEA components.
- Demonstrated the feasibility of using our optical diagnostic platform to make measurements of tape-cast solid oxide fuel cell layer uniformity.
- Continued collaboration with our industry partners, including three of DOE's competitively awarded manufacturing research and development (R&D) projects, in accordance with our project charter.
- Developed industry relationships and gained an understanding of quality control needs for the manufacture of high temperature cells.

Introduction

In FY 2005-2007, NREL provided technical support to DOE in developing a new key program activity: manufacturing R&D for hydrogen and fuel cell technologies. This work included a workshop on manufacturing R&D, which gathered inputs on technical challenges and barriers from the fuel cell industry, and subsequent development of a roadmap for manufacturing R&D. In late FY 2007, NREL initiated a project to assist the fuel cell industry in addressing these barriers, initially focusing on in-line quality control of MEA components. The project is utilizing the unique and well-established capabilities of NREL's National Center for Photovoltaics for developing and transferring diagnostic and process technology to the manufacturing industry.

Defects in MEA components differ in type and extent depending on the fabrication process used. The effects of these defects also differ, depending on their size, location

in the cell relative to the reactant flow-field, cell operating conditions, and which component contains the defect. Understanding the effects of these different kinds of defects is necessary to be able to specify and/or develop diagnostic systems with the accuracy and data acquisition/processing rates required for the speed and size scales of high-volume continuous manufacturing methods. Furthermore, predictive capabilities for manufacturers are critical to assist in the development of transfer functions and to enable assessment of the effects of material and process changes.

Approach

NREL and its partners are addressing the DOE manufacturing milestones listed above by evaluating, developing, and validating (in-line) diagnostics that will support the use of high-volume manufacturing processes for the production of MEAs and MEA component materials. Prioritization of this work is based on inputs from our industry partners on their critical manufacturing quality control needs. We are focusing on diagnostic capabilities not addressed by commercially available in-line systems, in particular evaluating methods to make areal rather than point measurements such that discrete defects can be identified. Given that specification of the required accuracy and precision of a diagnostic device to measure or identify material property variability or defects requires information about how this variability affects the functionality of the MEA, we are developing test methodologies to study the effects of size and/or extent of each important type of variability or defect. These results will additionally assist our industry partners in validating manufacturing tolerances for these materials, ultimately reducing scrap rates and cost, and improving supply chain efficiency. Finally, predictive models are being used at LBNL to understand the operational and design characteristics of diagnostic techniques by simulating the behavior of MEA components in different excitation modes. These results are being fed back to our design effort in configuring the diagnostics for in-line implementation. MEA models are also being utilized to understand the in-situ behavior of defect MEAs to guide and further elucidate experiments.

Results

Significant progress was made in moving our two diagnostic platforms, optical- and infrared-based, closer to in-line implementation. Benchtop prototype systems were designed and fabricated at NREL to enable validation of the operation and data acquisition of these techniques with a moving (as opposed to stationary) measurement target, a critical step in proving the viability of these techniques for in-line measurement. Using these systems, we successfully demonstrated the operation of the IR/DC and optical reflectometer diagnostics using GDM, CCM, and membrane sheet materials from our industry partners. Figure 1 shows the benchtop roller system used to validate

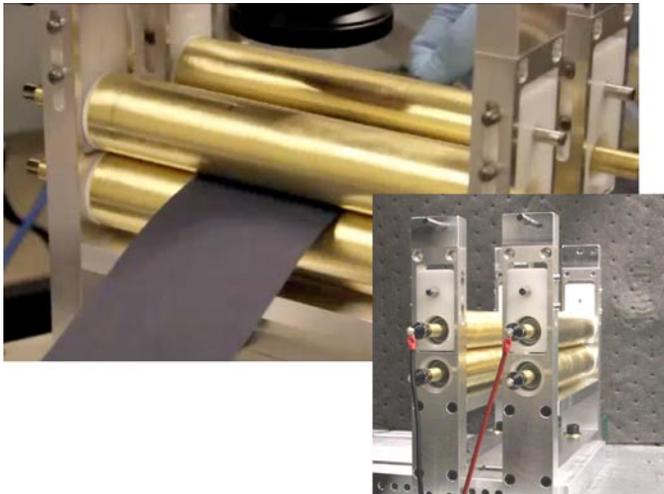

FIGURE 1. Benchtop Roller System (Inset: side view showing sliding electrical connectors.)

the IR/DC technique. Figure 2 shows an example from that validation, in this case scratch defects in a GDM sheet, and the resulting thermal response to those defects while the sheet was moving through the system. Studies were also performed to assess the response time and sensitivity, and to ensure that the technique would not damage the material during measurement. Models were developed by LBNL to assess the behavior of MEA materials during the DC excitation, enabling a full characterization of the operational space for the process, in terms of defect size and loading, detection criteria, response time, and magnitude of excitation. Figure 3 shows modeling and experimental results that indicate the response time for a given detection criteria and defect size as a function of the excitation magnitude. These simulations have fed back to the design specifications for an in-line system. We also performed in situ studies, using single and segmented cells, to determine

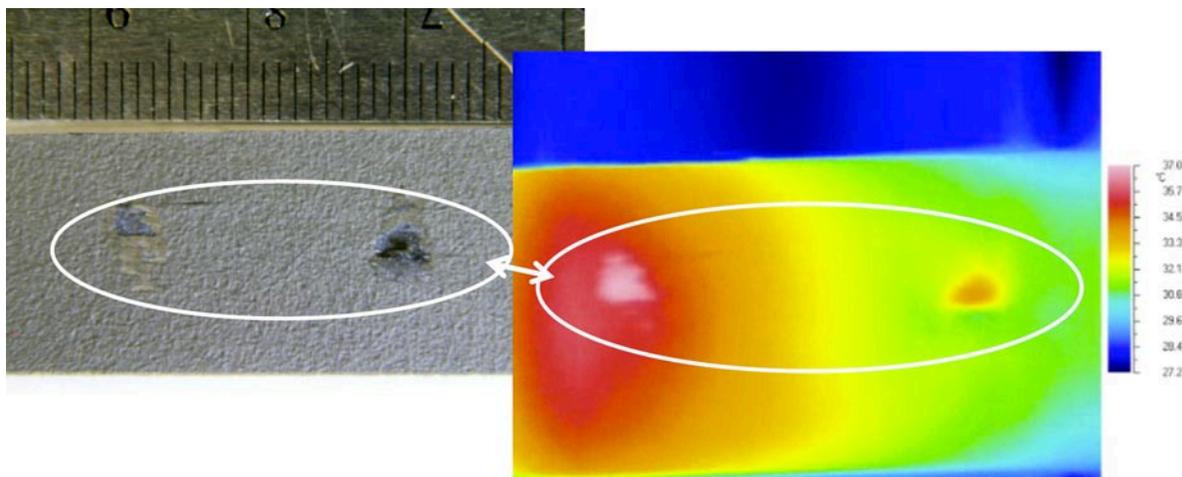

FIGURE 2. GDM sheet material with scratches and associated thermal response to those scratches, using the IR/DC technique on the benchtop roller system. The velocity of the sheet motion was approximately 10 feet per minute.

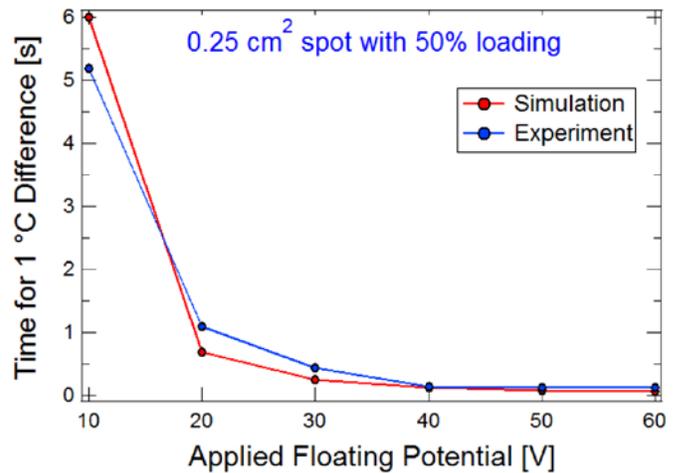

FIGURE 3. Comparison of modeling and experimental results indicating the response time for a given detection criteria and electrode defect size as a function of the DC excitation magnitude.

the effect on initial performance of MEA component defects, including electrode thin spots, voids, and mud-cracks, and GDM PTFE loading.

Continuing our efforts to expand the applicability of our optical reflectometer platform, we evaluated techniques to deconvolute membrane thickness from a composite measurement of a membrane still on its casting liner. This would enable the quality measurement farther forward in the manufacturing process, maximizing value. Depending on the difference in optical properties between the membrane and liner, the technique appears to be feasible. Software development to automate this calculation is ongoing. We also demonstrated the feasibility of using this diagnostic to measure the uniformity of tape-cast solid oxide fuel cell layers.

Future Directions

- Demonstrate the IR/DC and optical reflectometry diagnostics on our research web-line.
- Continue to use predictive modeling and single and segmented cell test methods to feed requirement and configuration information back to diagnostic development, device design, and detection algorithm assessment.
- Study how as-manufactured defects affect the performance of MEAs over time using standard or modified accelerated stress tests.
- Continue to work with our industry partners to ensure the relevance of our studies to their evolving needs and directions, including ongoing prioritization of diagnostic development needs.

- Ballard Power Systems (BPS), Burnaby, BC

Project Start Date: October 1, 2008

Project End Date: August 31, 2011

- (A) Lack of High-Volume Membrane Electrode Assembly Processes
- (F) Low Levels of Quality Control and Inflexible Processes

Contribution to Achievement of Manufacturing R&D Milestones

This project will contribute to achievement of the following DOE milestones from the Manufacturing R&D section of the Fuel Cell Technologies Program Multi-Year Research, Development and Demonstration Plan:

- Milestone 1: Develop prototype sensors for quality control of MEA manufacturing. (4Q, 2011)
- Milestone 2: Develop continuous in-line measurement for MEA fabrication. (4Q, 2012)
- Milestone 3: Demonstrate sensors in pilot scale applications for manufacturing MEAs. (4Q, 2013)
- Milestone 4: Establish models to predict the effect of manufacturing variations on MEA performance. (4Q, 2013)

FY 2011 Accomplishments

- Reduced GDL costs by 55% from \$36/kW to \$16/kW from FY 2008 to FY 2010 by:
 - Increasing the manufactured width from 40 cm to 80 cm wide.
 - Implementing process control tools to improve product uniformity, reducing the amount of ex situ testing, improving product yields and minimizing scrap rates.
 - Installing new equipment enabling the production of rolls over 800 m in length.
 - Developing empirical models to predict and control critical GDL properties early in the manufacturing process, thereby improving manufacturing efficiency.
- Manufactured multiple batches of various types of microporous layer (MPL) inks (10⁺ gallons per batch) using a 2" continuous mixer.
 - Purchased a rheometer to measure the visco-elastic properties of these various MPL inks:
 - Developed test methods to characterize our inks.
 - Collected data on both our standard and continuous inks.
 - Began to determine relationships between continuous mixing parameters and key fluid properties.

Fiscal Year (FY) 2011 Objectives

- Reduce the fabrication costs of gas diffusion layer (GDL) products by:
 - Reducing the number of process steps.
 - Replacing batch processes with continuous processes.
 - Utilizing in-line measurement tools to reduce costly ex situ testing.
- Develop and implement new, high volume GDL process technologies.
- Produce high-performance, low-cost GDLs at sufficient volumes for near-term fuel cell markets.
- Research, develop, and implement new in-line process control and measurement tools consistent with high volume manufacturing.
- Advance the understanding of the relationship between process parameters, ex situ GDL properties and fuel cell performance to maximize production of high-performance, low-cost GDLs for near-term markets.

Technical Barriers

This project addresses the following technical barriers from the Manufacturing R&D section of the Fuel Cell Technologies Program Multi-Year Research, Development and Demonstration Plan:

- Established mixing procedures to reduce the amount of agglomerations formed during the continuous mixing process.
- Successfully developed a process to filter and de-gas the continuous MPL inks.
- Manufactured rolls of GDL material combining the many-at-a-time (MAAT) coating process with continuously made inks:
 - Produced multiple rolls (~80 m) of both anode and cathode material within production specifications with minimal defects.
 - Verified fuel cell performance in both a single-cell and a 10-cell short-stack.
 - Optimized dryer profile utilizing non-contact infrared thermocouples throughout the oven and dew point sensors to prevent premature drying of top layer.
 - Due to modifications to the MPL ink formulations, the coating head slot heights were altered to eliminate coating defects and improve basis weight uniformity.
 - Improved GDL uniformity by installing mass flow meters for each MPL ink and continuously monitoring basis weight with an in-line basis weight tool.
- Identified, purchased and installed new process control tools for multilayer coating, in-line mixing and heat treatment processes:
 - Mass flow meters (in-line mixing/MAAT coating).
 - In-line basis weight tool.
 - In-line viscometers.
 - Non-contact thermocouples for MAAT drying conditions.
 - Non-contact thermocouples for heat treatment process (high temperature).
- Developed a method to relate continuous on-line Raman scanning, to slow off-line area Raman scanning in an effort to:
 - Investigate a link between poly-tetrafluoroethylene (PTFE) distribution throughout the GDL and GDL drying conditions.
 - Demonstrate that on-line Raman scanning will detect the differences at required speeds for an on-line manufacturing tool.
 - Determine if differences in PTFE distribution throughout the GDL have an impact on critical ex situ properties of GDL and/or in situ fuel cell performance.
- Examined each step of the manufacturing process and determined relationships between specific process parameters and critical GDL properties.
- Developed empirical models to predict and control critical GDL properties early in the manufacturing process.
- Implemented methods to adjust the manufacturing process to center GDL properties within production specifications to ensure proper functionality.
- Improved manufacturing capacity 4-fold from FY 2008 to FY 2010.
 - Additional capacity increases are expected to reach ~9-fold with the full implementation of continuous mixing and multilayer coating technologies demonstrated in this project (requires additional capital investment to complete).

Introduction

This project addresses the Manufacturing R&D sub-program's goal of research, development and demonstration of technologies and processes that reduce the manufacturing cost of proton exchange membrane fuel cell systems. Specifically, this project reduces the fabrication costs of high-performance GDL products, while also increasing manufacturing capacity and improving product uniformity. The end result of this project is the production of low-cost, high-performance GDLs for near-term fuel cell markets, such as back-up power or materials handling. A conceptual design of a Greenfield manufacturing plant that is capable of meeting the 2015 GDL target price of \$4/kW at specified volumes will also be developed.

Approach

The largest barrier to the commercialization of fuel cell products is cost. The cost of the GDL was evaluated at the end of 2008 and found to be \$36/kW, almost 10 times the DOE cost target for 2015. A breakdown of this cost revealed that the majority of the fabrication cost of GDLs was due to manufacturing labor, specifically for ink mixing, coating and quality control.

It was believed that much of that cost could be removed by reducing the number of process steps, replacing slow batch processes with faster continuous processes, and utilizing modern on-line tools to improve product quality and reduce the amount of ex situ testing. In addition to these process modifications, it was also critical to determine the relationships between manufacturing parameters and critical GDL properties. From this understanding, empirical models will improve production controls, ensure product performance, and aid in the development of next generation GDLs that can meet the needs of state-of-the-art membranes and catalysts. Although the costs cannot be reduced to the DOE program target through this project alone, Ballard will use the knowledge gained in this project to design a Greenfield facility that is capable of producing

GDLs at or below \$4/kW which should help meet the DOE stack target cost of \$30/kW in 2015 at appropriate manufacturing volumes.

Results

Throughout this project, BMP has been able to reduce the fabrication costs of GDLs by 55% from \$36/kW to \$16/kW, as shown in Figure 1. This has been accomplished by increasing the manufactured width of the GDL from 40 cm to 80 cm, installing new web-handling equipment to allow for processing of rolls in excess of 800 m long, implementing better process controls, and incorporating an empirical process model which has resulted in improved process yields and reduced scrap rates. As a result of these efforts, the plant capacity has been increased 4-fold, as shown in Figure 2, which allows for production of low-cost, high-performance GDLs at volumes suitable for near-term markets.

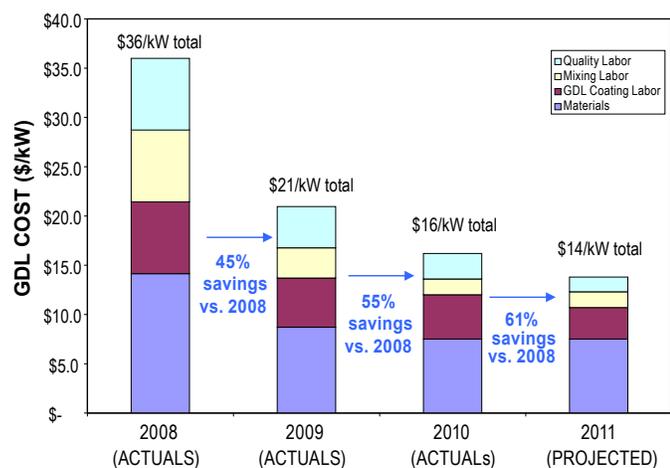

FIGURE 1. GDL Cost Reduction Data

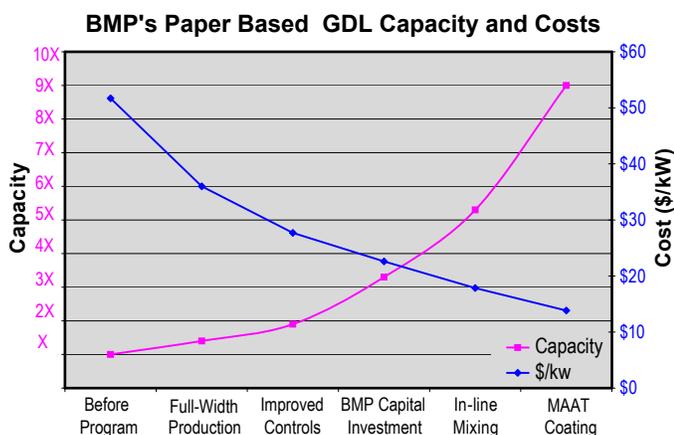

FIGURE 2. Impact of Various Program Milestones on Manufacturing Capacity and GDL Cost

Ballard has also demonstrated methods for future cost reductions based on the implementation of MAAT coating and continuous mixing. Multiple short rolls (~80 m) of anode and cathode GDL designs have been manufactured to date, demonstrating that GDLs manufactured with this new technology are similar to standard baseline materials [1]. Ex situ validation of GDLs made with these methods is shown in Figure 3, while in situ validations are still being completed and will be available in the next quarterly report. This validation work is different than previously reported work because it combines both MAAT coating and continuous mixing technologies together for the ultimate low-cost GDL design. Additional capital investments will be required by Ballard to fully integrate these new technologies into the GDL manufacturing process, but this work is critical in demonstrating their viability for GDL production.

In addition to the cost reduction work, Ballard has determined relationships between critical GDL properties and fuel cell durability and performance. Additionally, BMP has examined every step in their manufacturing process to find relationships between manufacturing process variables and these critical GDL properties [1]. These relationships have led to the development of empirical models, which allow BMP to predict and control critical GDL properties early in the manufacturing process. This understanding also allows BMP to make adjustments during the manufacturing process to meet specific customer targets, allowing for a more stable, consistent product, that improves yield rates and cell performance. This knowledge will also allow for the development of enhanced GDL designs that are tailored for a specific application (e.g. air-cooled vs. liquid-cooled) and should help in manufacturing GDLs with tight specifications.

The Pennsylvania State University, under the direction of Dr. Michael Hickner, is working with BMP to develop an in-line method for measuring the chemical homogeneity of the GDL. This work has led to the discovery of a potential link between PTFE distribution and GDL drying conditions,

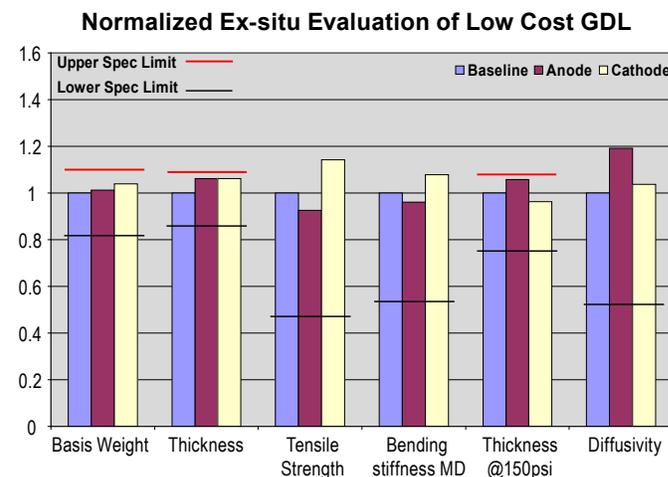

FIGURE 3. Ex Situ Evaluation of Low-Cost Anode and Cathode GDL Materials

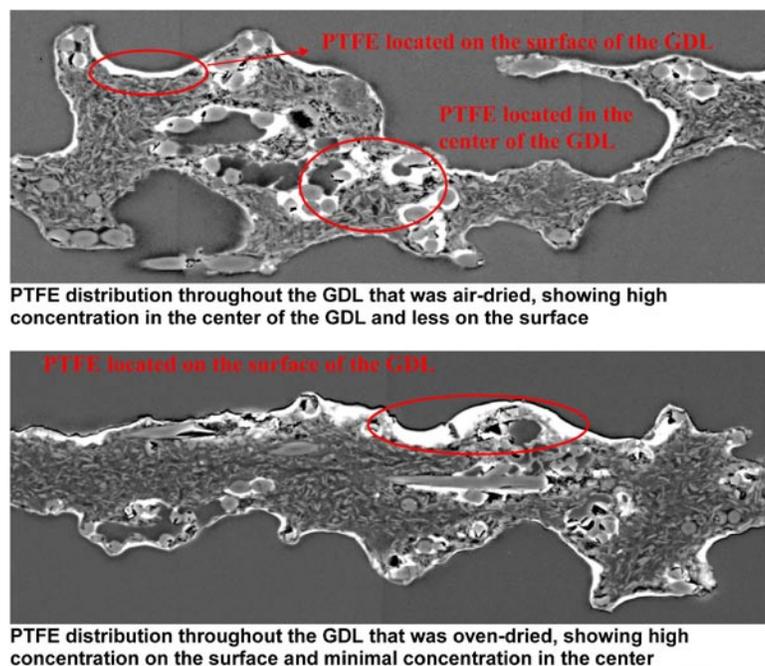

FIGURE 4. Impact of Drying Conditions on PTFE Distribution throughout the GDL

as shown in Figure 4. Dr. Hickner's team has demonstrated that on-line Raman scanning can detect differences in the PTFE distribution at speeds high enough to be used as an on-line manufacturing tool. In an effort to further this understanding, BMP has manufactured a variety of GDL designs with different PTFE loadings that were exposed to various drying profiles. Dr. Hickner's team is now working on determining if differences in PTFE distribution throughout the GDL are seen in these samples, while BMP and BPS are working to determine if there is a significant impact on critical ex situ properties of GDL and/or in situ fuel cell performance. This work will be valuable to the fuel cell community as a whole, by either providing a method to determine the PTFE distribution throughout the GDL with an on-line tool or demonstrating that variations in the PTFE distribution do not impact critical GDL properties or fuel cell performance.

Conclusions and Future Directions

BMP was able to reduce the fabrication costs of GDLs by 55%, while increasing manufacturing capacity 4-fold and improving product quality throughout this project. Multilayer coating and in-line mixing technologies have been successfully combined and ex situ testing showed that both anode and cathode materials were within production specification, while in situ testing (both single cell and short stack testing) is underway to validate fuel cell performance. These technologies will lead to further cost reductions (~65% from FY 2008) and capacity increases (~4-fold from FY 2008) with appropriate capital investments by Ballard

to bring them on-line. In addition, Ballard has been able to determine relationships between critical GDL properties and fuel cell performance/durability. BMP has determined relationships between various manufacturing parameters and these critical GDL properties, which will allow for more uniform GDL production, improved GDL design and increased production yields. This work is beneficial for production of high-performance, low-cost GDLs for near-term fuel cell markets, as well as the development of new GDLs to meet the needs of state-of-the-art membranes and catalysts.

The Pennsylvania State University, under the direction of Dr. Michael Hickner, has determined a method to measure PTFE distribution in the GDL using Raman Scanning at rates fast enough to be considered for use as an on-line tool. They are currently examining a variety of GDL designs with different PTFE loadings made with different drying profiles to determine if there are differences in PTFE distribution. This work, combined with ex situ GDL measurements and in situ cell performance data gathered by Ballard, is important to understand how variations in the PTFE distribution throughout the GDL influence fuel cell performance, if at all.

In the final months of this project the activities include:

- Production of commercial length rolls of both anode and cathode GDL designs using both continuously made inks and MAAT coating.
- Validation of these low-cost GDL materials utilizing ex situ validation as well as single-cell, short-stack and full-stack testing.
- Determination of manufacturing capability with these new process technologies with a goal of achieving 6 sigma standards.
- Completion of the design of a Greenfield facility capable of producing GDLs that meet the DOE 2015 target at specified volumes.
- Determination of the impact of PTFE distribution on both ex situ GDL properties and in situ fuel cell performance, as well as development of a measurement process that could be used as an on-line process control tool for GDL manufacturing.
- Pennsylvania State University will complete their work on Raman scanning and deliver a measurement procedure that is capable of being converted to an on-line process control tool with the appropriate capital investment.

- Pacific Northwest National Laboratory, Richland, WA
- Cincinnati Test Systems, Cleves, OH

Project Start Date: September 1, 2008

Project End Date: June 14, 2011

- **Milestone 9:** Select stack assembly processes to be developed. (4Q, 2010)
- **Milestone 10:** Develop automated pilot scale stack assembly processes. (4Q, 2012)
- **Milestone 12:** Demonstrate pilot scale processed for assembling stacks. (4Q, 2013)

FY 2011 Accomplishments

- Tested and evaluate leak-test suite prototype.
- Achieved five part per hour leak test rate on the prototype.
- Demonstrated that the stack test labor time is reduced dramatically.
- Demonstrated that the stack leak failure is reduced significantly.
- Demonstrated that the prototype can accurately detect leaks in stacks.
- Demonstrated that the prototype does not cause any new failure modes in fuel cell stacks and systems.

Fiscal Year (FY) 2011 Objectives

- Design a modular, high-volume fuel cell leak-test suite.
- Performance leak tests in-line during assembly and break-in steps.
- Demonstrate improved fuel cell stack yield rate.
- Reduce labor time.
- Reduce fuel cell stack manufacturing cost.

Technical Barriers

This project addresses the following technical barriers from the Manufacturing section (3.5.5) of the Fuel Cell Technologies Program Multi-Year Research, Development and Demonstration Plan:

(F) Low Levels of Quality Control and Inflexible Processes

Contribution to Achievement of DOE Manufacturing Milestones

This project will contribute to achievement of the following DOE milestones from the Fuel Cells section of the Fuel Cell Technologies Program Multi-Year Research, Development and Demonstration Plan:

Introduction

There are three fluid circuits in a fuel cell stack. Any fluid leakage between these circuits or to the external atmosphere leads to reduced individual cell or stack performance and results in a failure during stack testing. Fuel cell stacks are typically hand assembled and tested, and it is very time-consuming. Furthermore, the leak-test equipment is often composed of expensive analytical devices, with extensive and excessive capabilities, that are not well suited to rapid testing of stack assemblies in medium- or high-volume manufacturing environments. High labor content and expensive test equipment limit the amount of online leak checks during the assembly process, leading to high scrap rates and low yields.

The development of a modular, high-volume fuel cell leak-test suite and process is proposed to address these challenges by reducing labor content; providing more robust, high confidence automated testing; and increasing the speed and throughput at which manufacturing is performed. Each leak test component will be highly specialized to its specific task and optimized for high throughput, thereby allowing for dramatic cost savings. A variety of methods will be employed to test for leaks between the fuel cell fluidic paths and the environment during the entire process from build to break-in to final test. The test suite will enable manufacturers to select modular test components as needed.

Approach

Six leak-test methods were proposed in the project. These tests include crossover current, current interrupt, voltage decay, pressure decay, flexo-tiltometer test, and fuel cell sensor for coolant leak. These methods will be investigated, and some will be selected to implement in the leak-test suite. These tests will automatically perform in-line during fuel cell stack manufacturing. The leak-test methods not only check the overall leakage, but also identify the location of leak and accelerate the diagnostics and remediation of fuel cell stacks.

Phase I of the project focuses on the analysis of current manufacturing processes, stack failure modes, and leak-test processes. A verity of leak-test methods will be surveyed, and recommendations for the leak-test suite will be made. Leak-test suite prototype will be designed, fabricated, and evaluated. A leak-test suite with 50 stacks per hour capability will be designed. Phase II will focus on pilot production line modification, leak-test suite fabrication, integration, and verification. A limited production test run will be carried out to validate the 50 stacks per hour operation.

Results

Twenty-three fuel cell stacks were built and tested on the leak-test suite prototype. There were 12 cells in each stack. The Celtec-P 1000 high temperature membrane electrode assembly with 18 cm² active area was used. Pressure decay (PD), crossover current (CC), and open-circuit voltage (OCV) decay were used to detect leak in stacks. The results are shown in Table 1. This demonstrated that 95% of leaks can be detected by the prototype. The leak test times are shown in Table 2. The average leak test time is 590 seconds, and the leak test rate is 6 parts per hour, which exceeds the Phase I milestone: 5 parts per hour.

TABLE 1. Leak Test Results

	YES	NO
PD correctly confirms CC or OCV results	19	4
CC correctly detects failure on retest	15	0
OCV correctly detects failure on retest	15	0
CC/OCV correctly detects swap or replacement	24	0

TABLE 2. Leak Test Time

Leak Test Process	Test Time (sec)
Pressure decay	227
Crossover current	253
OCV decay	60
Flexo-tiltometer	50
Total	590

Five stacks were built and tested on the leak-test suite prototype. These stacks passed leak, break-in, and performance tests. Then they were subjected to 30-day life test with one start/stop per day. The stack life test results are shown in Figure 1. All stacks completed life test and meet exit criteria. One cell in stack 084618-02 failed due to the fuel starvation, and was replaced at ~400 hr. However, this type of failure is occasionally observed in production stacks, so the failure should not be attributed to the prototype. Overall, the stack life test demonstrates that leak-test suite prototype does not cause new failure modes in stack.

Three stacks were built and tested on the leak-test suite prototype. These stacks passed leak, break-in, and performance tests. Then they were integrated into fuel cell systems. The system tests include static/dynamic load, cartridge run, -5°C performance, 50°C performance, emission, surface temperature, and polarization curve. System 26 and 50 passed all tests. System 45 passed all tests except emission and polarization curve test (Table 3). During diagnostics, a stainless steel tube on fuel processor broke off. This indicated there was a bad welding in the fuel line. This might cause fuel leak and result in fuel starvation in fuel cell. Later, an air compressor was found to have a manufacturing defect that caused an air leak. The failures

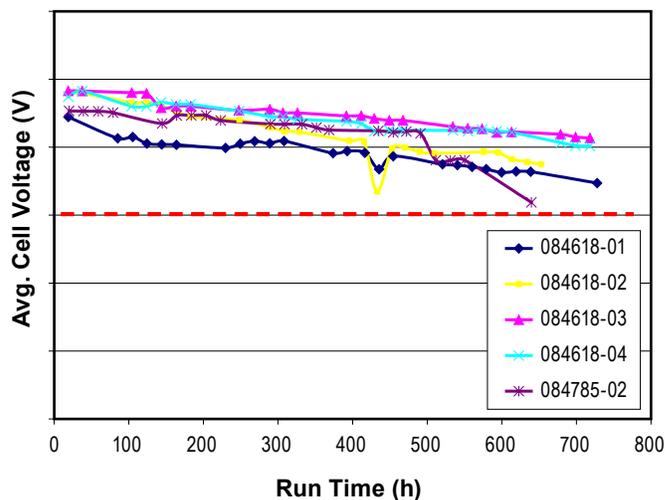

FIGURE 1. Fuel Cell Stack 30-Day Life Test

TABLE 3. System Test Results

System Tests	25E1LC0026	25ENDY0050	25E1LC0045
Static/Dynamic Load	Pass	Pass	Pass
Cartridge Run	Pass	Pass	Pass
-5C Performance	Pass	Pass	Pass
50C Performance	Pass	Pass	Pass
Emission	Pass	Pass	Fail
Surface Temperature	Pass	Pass	Pass
Polarization Curve	Pass	Pass	Fail

in the system test are due to the balance of plant component failure and not related to the fuel cell stack. The system validation test demonstrates the leak test suite prototype does not cause new failure modes in the fuel cell stack.

Conclusions and Future Directions

The conclusions include the following:

- The fuel cell stack leak-test suite prototype was tested and evaluated. The prototype achieved five part per hour leak test rate. The prototype is fully automated, significantly reducing the stack test labor time.
- The validation test demonstrated that the prototype can accurately detect leaks in stacks. The leak test processes do not cause any new failure modes in fuel cell stack and system.

Contract Number: DE-FC36-086018052

Subcontractors:

- UTC Power, South Windsor, CT
- University of Delaware, Newark, DE
- University of Tennessee, Knoxville, TN

Project Start Date: October 1, 2008

Project End Date: June 30, 2013

Fiscal Year (FY) 2011 Objectives

The overall objective of this project is to develop a unique, high-volume manufacturing processes that will produce low-cost, durable, high-power density 5-layer (5-L) membrane electrode assemblies (MEAs) that minimize stack conditioning:

- Manufacturing process scalable to fuel cell industry MEA volumes of at least 500k systems/year.
- Manufacturing process consistent with achieving \$15/kW_e DOE 2015 transportation stack cost target.
- The product made in the manufacturing process should be at least as durable as the MEA made in the current process for relevant automotive duty cycling test protocols.
- The product developed using the new process must demonstrate power density greater or equal to that of the MEA made by the current process for relevant automotive operating conditions.
- Product form is designed to be compatible with high-volume stack assembly processes: 3-layer (3-L) MEA roll-good (anode electrode + membrane + cathode electrode) with separate rolls of gas diffusion media (GDM).

- The stack break-in time should be reduced to 4 hours or less.

Phase 2 Objectives:

- Low-Cost MEA Research and Development (R&D)
 - New 3-L MEA Process Exploration
 - Investigate equipment configuration for low-cost MEA production.
 - Investigate raw material formulations.
 - Map out process windows for each layer of the MEA.
 - Mechanical Modeling of Reinforced 3-L MEA
 - Use model to optimize membrane reinforcement for 5,000+ hour durability and maximum performance.
 - Develop a deeper understanding of MEA failure mechanisms.
 - 5-L Heat and Water Management Modeling
 - Optimization of GDM thermal, thickness, and transport properties to enhance the performance of thin, reinforced membranes and unique properties of direct-coated electrodes using a validated model.
 - Optimization
 - Execute designed experiments which fully utilize University of Delaware (UD) and University of Tennessee, Knoxville (UTK) modeling results to improve the new MEA process and achieve the highest possible performance and durability.
 - MEA Conditioning
 - Evaluate potential for new process to achieve DOE cost targets prior to process scale up (Go/No-Go decision).
- Scale-Up and Process Qualification
- Stack Validation

Technical Barriers

This project addresses the following technical barriers from the Manufacturing section of the Fuel Cell Technologies Program Multi-Year Research, Development and Demonstration Plan:

- (A) Lack of High-Volume Membrane Electrode Assembly (MEA) Processes
- (D) Manual Stack Assembly

Contribution to Achievement of DOE Manufacturing Milestones

This project will contribute to achievement of the following DOE milestones from the Manufacturing section of the Fuel Cell Technologies Program Multi-Year Research, Development and Demonstration Plan:

3.5 Manufacturing R&D/ Fuel Cells/ Task 1: Membrane and MEA

4. Establish models to predict the effect of manufacturing variations on MEA performance. (4Q, 2013)

3.4 Fuel Cells/ Task 3: Membrane Electrode Assemblies Meeting All Targets

38. Evaluate progress toward 2015 targets. (4Q, 2012)

FY 2011 Accomplishments

- Direct Coating Process Development
 - The primary path for the new 3-L MEA process has succeeded in incorporating the previously modeled process improvements which indicated potential for a 25% reduction in high-volume 3-L MEA cost.
 - Lab-scale development of the new 3-L MEA process is nearing completion:
 - Primary and alternative paths have been determined.
 - Current density of un-optimized direct-coated electrodes is equivalent to or better than current commercial electrodes over a robust range of automotive operating conditions.
- Gore has demonstrated mechanical durability of a 12 micron expanded polytetrafluoroethylene (ePTFE) reinforced membrane. In previous testing, GORE™ MEAs exceeded 2,000 hours of accelerated mechanical durability testing, which has been equated to achieving 9,000 hours of membrane durability in an 80°C automotive duty cycle. This exceeds the DOE 2015 membrane durability target of 5,000 hours. Gore's 12 micron ePTFE reinforced membrane technology has been successfully incorporated into the lab-scale new 3-L MEA process.
- A quasi-static elastic/plastic layered structure MEA mechanical model has been modified to include visco-elastic/plastic behavior. Mechanical property experiments which are required to calculate model input parameters are 95% complete. The final model will be used to predict reinforced MEA mechanical lifetime for a variety of temperature and relative humidity cycling scenarios. The model will also be used to explore different reinforcement strategies and optimize mechanical durability of the MEA structure targeted by the new low-cost process.

- 5-Layer Heat & Water Management Model development at UTK is complete and the experimental test progress is on track to enable efficient optimization of GDM for the new 3-L MEA.

Introduction

Over the past 20 years, great technical progress has been made in the area of improving power density and durability of fuel cell stacks, so much so that most of the requisite technical targets are now within reach. Yet, three major technical challenges remain. First and foremost is meeting the cost targets. The second challenge is producing components that are amenable for use in a high-speed, automotive assembly line. One impediment to this latter goal is that stack components must currently go through a long and tedious conditioning procedure before they produce optimal power. This so-called “break-in” can take many hours, and can involve quite complex voltage, temperature and/or pressure steps. These break-in procedures must be simplified and the time required reduced, if fuel cells are to become a viable power source. The third challenge is to achieve the durability targets in real-world operation. This project addresses all three challenges: cost, break-in time, and durability for the key component of fuel cell stacks: MEAs.

Approach

- The overall objective of this project is to develop unique, high-volume manufacturing processes for low-cost, durable, high-power density 3-L MEAs that require little or no stack conditioning. In order to reduce MEA and stack costs, a new process will be engineered to reduce the cost of intermediate backer materials, reduce the number and cost of coating passes, improve safety and reduce process cost by minimizing solvent use, and reduce required conditioning time and costs. MEA mechanical durability will be studied and optimized using a combination of ex situ mechanical property testing, non-linear mechanical model optimization, and in situ accelerated mechanical durability testing. Fuel cell heat and water management will be modeled to optimize electrode and GDM thermal, geometric, and transport properties and interactions. Unique enabling technologies that will be employed in new process development include:
 - Direct coating which will be used to form at least one membrane–electrode interface.
 - Gore's advanced ePTFE membrane reinforcement and advanced perfluorosulfonic acid ionomers which enable durable high-performance MEAs.
 - Advanced fuel cell testing and diagnostics.

Results

Low-Cost MEA Process Development

The primary path has changed during the past year and process development for the current primary path is progressing rapidly.

- Previous Primary Path
 - Process step 1: Direct coat cathode electrode on a carrier-film-supported reinforced membrane.
 - Process step 2: Remove carrier film and direct coat anode electrode on 2-layer intermediate.
- Current Primary Path
 - Process step 1: Coat bottom electrode on low-cost, non-porous backer.
 - Process step 2: Direct coat reinforced membrane on top of the bottom electrode.
 - Process step 3: Direct coat top-side electrode on top of the reinforced membrane.

The alternate path is to directly coat the anode electrode onto a backer-supported reinforced half-membrane to make an anode-side 1.5-layer intermediate rolled-good. The cathode electrode is then directly coated onto a backer-

supported reinforced half-membrane in a similar process. In the final step, the backers are removed from the anode-side and cathode-side 1.5-layers intermediates and the webs are laminated together to form the 3-L product.

Electrodes made using lab-scale versions of the current primary path process equipment have demonstrated performance equivalent to or better than the current commercial electrodes across a broad range of operating conditions. This is a substantial improvement over the previous primary path which produced electrodes that were equivalent, at best, to the current commercial electrodes. Figures 1 and 2 show performance of direct coated electrodes paired with opposing control electrodes in a range of operating conditions which can be used to assess the viability of an MEA for different applications (automotive, stationary, portable, etc.), or for dynamic operation within a single application.

Coating research during the past year focused on developing the new primary path process and understanding the interactions between cathode ink formulation and low-cost backer for the current primary path, in which the cathode is the first layer to be coated in the 3-L MEA. Future experiments will combine direct-coated anodes and direct-coated cathodes and test the durability of direct-coated electrodes.

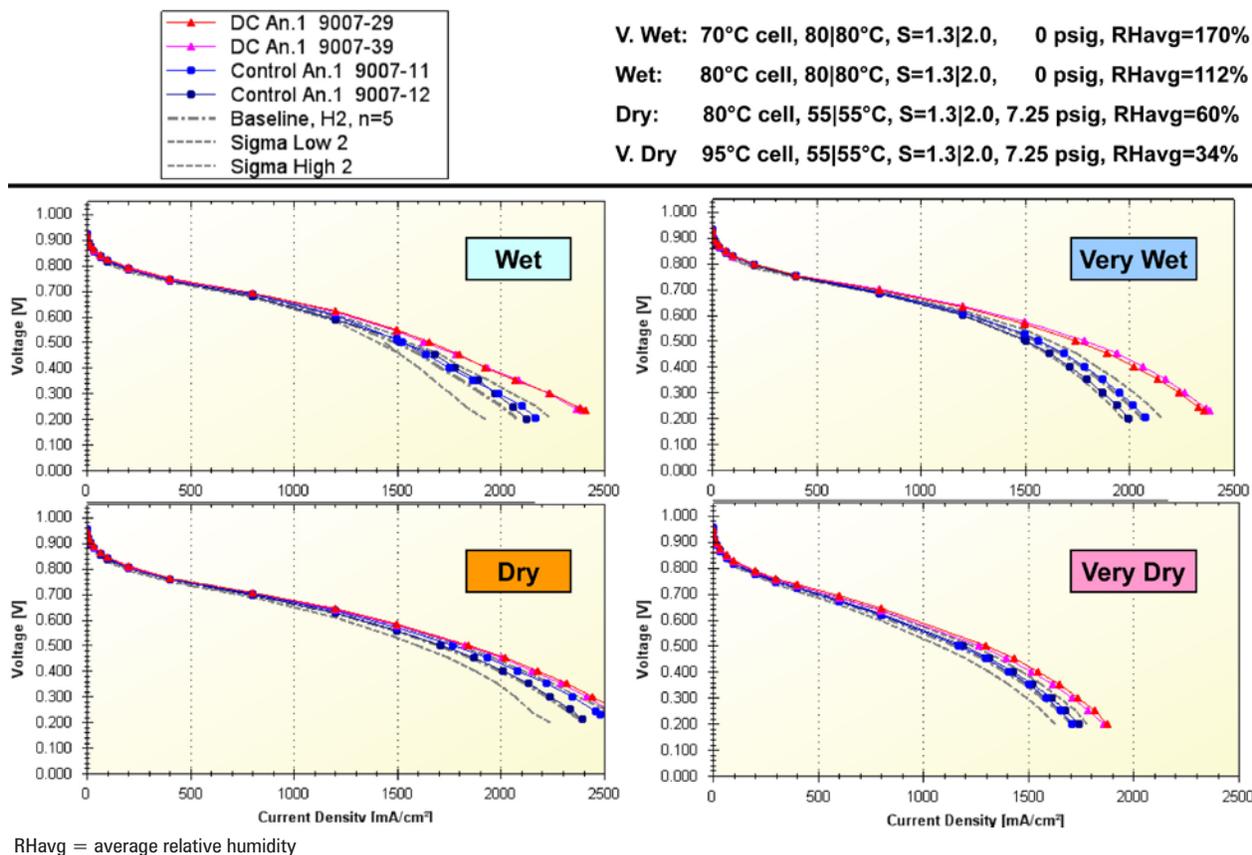

FIGURE 1. Direct Coated Anode Performance (PL = Platinum loading in mg/cm²)

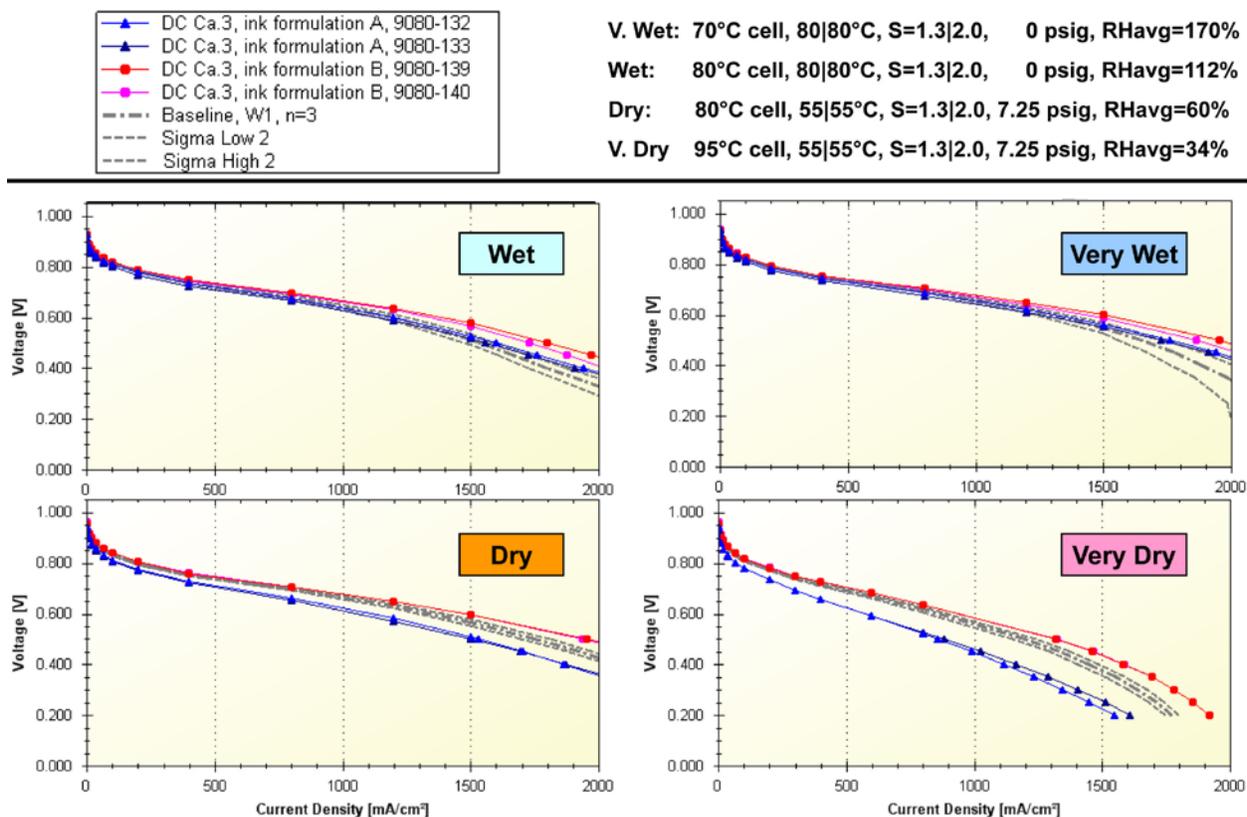

FIGURE 2. Direct Coated Cathode Performance (PL = Platinum loading in mg/cm²)

Mechanically Durable 12 μm Reinforced Membrane

Gore has successfully incorporated a mechanically durable 12 μm reinforced membrane into the current primary path process. The 12 μm membrane construction has also demonstrated high performance due to reduced resistance and increased waster back-diffusion (see Figure 3). In previous testing, GORE™ MEAs exceeded 2,000 hours of accelerated mechanical durability testing, which has been equated to achieving 9,000 hours of membrane durability in an 80°C automotive duty cycle. This exceeds the DOE 2015 membrane durability target of 5,000 hours. The accelerated mechanical durability testing protocol is summarized below:

Tcell (°C)	Pressure (kPa)	Flow (Anode/Cathode, cc/min)
80	270	500 N ₂ /1,000 N ₂

- Cycle between dry feed gas and humidified feed gas
- (sparger bottle temp = 94°C)
- Dry feed gas hold time: 15 seconds
- Humidified feed gas hold time: 5 seconds
- For further protocol information, see: W. Liu, M. Crum [1]

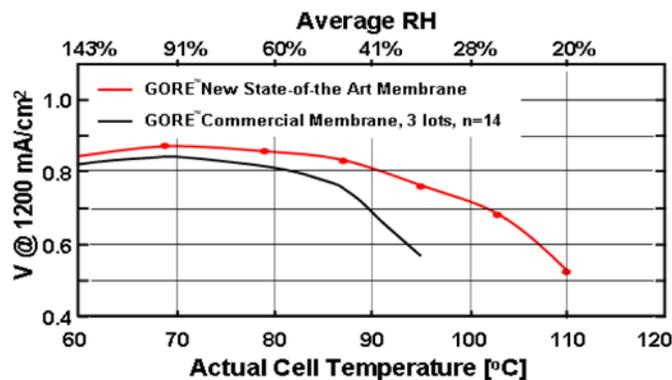

FIGURE 3. Performance of Thin, Mechanically Durable Reinforced Membrane

Mechanical Modeling of Reinforced 3-L MEA (UD)

A quasi-static elastic/plastic layered structure MEA mechanical model has been modified to include visco-elastic/plastic behavior. Mechanical property experiments which are required to calculate model input parameters are 95% complete.

Nafion® 211 membrane is used for the model membrane and the temperature, relative humidity, and time dependant

properties are calculated from the ongoing experimental results. The viscous properties are modeled using a 2-layer viscoplastic constitutive model. This material model consists of an elastoplastic “arm” that is in parallel with an elastoviscous “arm.” The elastoplastic arm consists of an elastic spring (stiffness K_p) and a plastic component (yield stress, σ_y and hardening H'). Yielding according to the Mises criterion is used here. The elastoviscous arm has two elements, one spring (stiffness K_v) and one dashpot (using a time hardening law $\dot{\epsilon}_v = A\sigma_v^n$). Thus, the instantaneous elastic stiffness of the material is the sum of the elastic elements, $K_p + K_v$. In summary, the parameters that are required for this model are K_p , σ_y , H' , K_v , A and n . These properties are determined from the experimental results. Figure 4 shows the modeled membrane stress as a function of membrane water fraction for two cycling scenarios using preliminary experimental data.

Tensile testing was conducted for a range of displacement rates to investigate the influence of this parameter on the mechanical response. The rates were selected so that the full visco-elastic-plastic constitutive equations can be determined. The relationships obtained from the MEA testing are “composite properties,” combining the properties of the membrane with the electrodes. The constitutive equations for the electrodes will be obtained

via reverse analysis. The experimental results have shown that the mechanical response of Nafion® 211 membrane and the MEA is dependent on temperature and humidity as well as displacement rate. Results also indicate that lower temperature, lower humidity or faster displacement rate result in a larger stress for a given strain.

5-L Heat and Water Management Modeling (UTK)

Membrane electrode assemblies and diffusion media materials were selected and experimental testing was initiated. Computationally, an initial first round of two-dimensional single-phase computational model simulation was completed to simulate the impact of diffusion media and membrane thickness and thermal properties. This analysis has enabled some understanding of the consequences of the various micro/macro diffusion media designs. The thermal properties of the diffusion media and micro-porous layer were shown to be critical to facilitate proper water management and are critical engineering parameters. Later, computational simulations were upgraded to include multi-phase flow.

Conclusions and Future Directions

The combination of Gore’s advanced materials, expertise in MEA manufacturing, and fuel cell testing with the mechanical modeling experience of University of Delaware and the heat and water management experience of University of Tennessee enables a robust approach to development of a new low-cost MEA manufacturing process.

- Electrodes made using lab-scale versions of the current primary path process equipment have demonstrated performance equivalent to or better than the current commercial electrodes across a broad range of operating conditions. Future work will focus on combining direct coated anodes and cathodes as well as accelerated stress testing to ensure that durability of the new, direct-coated MEAs is equivalent to or better than the current commercial control MEA.
- Fuel cell heat and water management modeling will be used to efficiently optimize electrode and GDM thermal, geometric, and transport properties and interactions. Direct coated electrodes will be paired with the most appropriate GDM materials identified in this study. In this way, GDM will enable maximum performance and durability of the low cost 3-L MEA.
- A quasi-static elastic/plastic layered structure MEA mechanical model has been modified to include visco-elastic/plastic behavior.

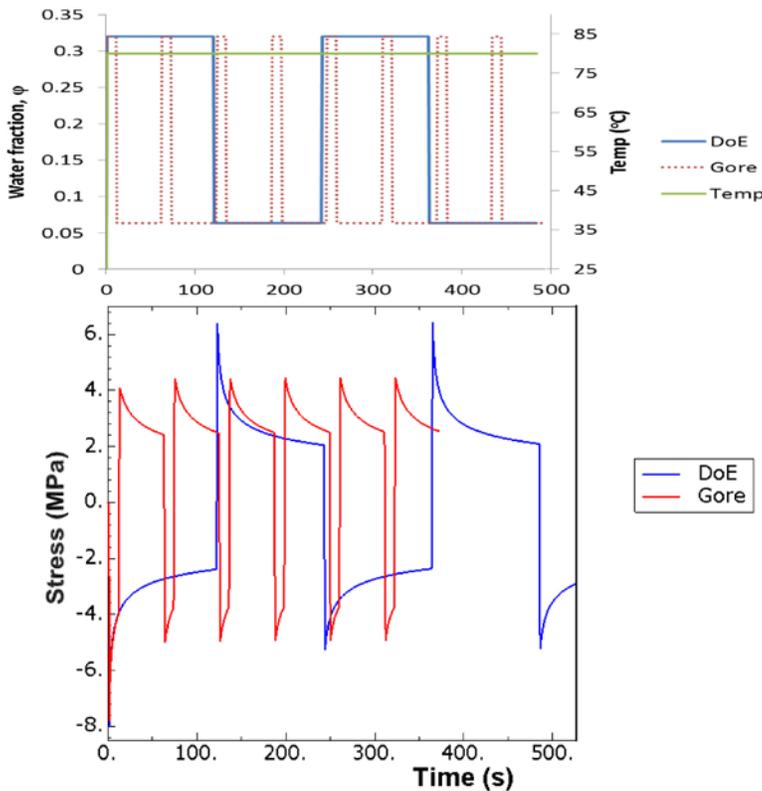

FIGURE 4. Modeled Membrane Stress as a Function of Membrane Water Fraction for Two Cycling Scenarios

Mechanical property experiments which are required to calculate model input parameters are 95% complete. When data collection is complete, the model will be validated with MEA accelerated durability testing. The final model will then be used to predict reinforced MEA lifetime for a variety of temperature and relative humidity cycling scenarios. The model will also be used to explore different reinforcement strategies and optimize mechanical durability of the MEA structure targeted by the new low-cost process.

Project Start Date: September 1, 2008
Project End Date: June 30, 2012

Fiscal Year (FY) 2011 Objectives

The high level objective of the proposed work is to enable cost-effective, high-volume manufacture of high- (160-180°C) and low-temperature (<100°C) proton exchange membrane fuel cell (PEMFC) membrane electrode assemblies (MEAs) by:

- Achieving greater uniformity and performance of high-temperature MEAs through the application of adaptive process control (APC) combined with effective in situ property sensing to the MEA pressing process.
- Greatly reducing MEA pressing cycle time through the development of novel, robust ultrasonic bonding processes.

Technical Barriers

This project addresses the following Manufacturing R&D technical barriers in the Manufacturing R&D section (3.5.5) of the Fuel Cell Technologies Program Multi-Year Research, Development and Demonstration Plan:

- (A) Lack of High-Volume Membrane Electrode Assembly (MEA) Processes
- (F) Low Levels of Quality Control and Inflexible Processes

Contribution to Achievement of DOE Manufacturing Milestones

This project will contribute to achievement of the following DOE milestones from the Manufacturing R&D section (3.5.7) of the Fuel Cell Technologies Program Multi-Year Research, Development and Demonstration Plan:

- **Milestone 2:** Develop continuous in-line measurement for MEA fabrication. (4Q, 2012)
- **Milestone 3:** Demonstrate sensors in pilot scale applications for manufacturing MEAs. (4Q, 2013)
- **Milestone 4:** Establish models to predict the effect of manufacturing variations on MEA performance. (4Q, 2013)

FY 2011 Accomplishments

- Added APC capability to Rensselaer's MEA thermal bonding station.
- Designed, built, and tested temperature-controlled stack hardware, servo press, and fuel cell test stand that can handle one MEA and short stacks of 5 and 10 high-temperature MEAs (50 cm² active area) bonded using thermal pressing and APC or ultrasonics.
- Designed, built and tested thermal and ultrasonic bonding tools, component assembly and laser cutting fixtures, and single cell test hardware for thermal pressing, ultrasonic bonding, and characterization of larger scale high-temperature MEAs (140 cm²).
- Found that heat treatment (to boil off excess water), low pressing pressure, low anvil support backer stiffness, and high booster amplitude were optimal process parameters for ultrasonic bonding of high-temperature MEAs.
- Created a vibration model coupled with thermal finite element analysis (FEA) model to accurately predict transient temperatures through MEA thickness during ultrasonic bonding.
- Found that current heat treatment time can be reduced as much as 50% without adversely affecting performance, membrane thickness and acid concentration in the MEA.
- Designed, built, and tested thermal and ultrasonic bonding tools, component assembly and laser-cutting fixtures, and single cell test hardware for low-temperature (Nafion[®]) MEAs (10 cm² active area).
- Found that MEAs sealed ultrasonically with optimized process parameters exhibit excellent stability (no cell voltage degradation and minimal cell internal resistance change) under extreme start/stop operating conditions over a period of 200 hours.

- New cost model predictions between Phase I and Phase II based on actual experimental data include lower cost reductions for implementing APC (29% vs. 38%) but higher reductions for implementing ultrasonics (90% vs. 84%).

Introduction

To realize the tremendous potential that fuel cell technology has to improve the world's environment and reduce our dependence on fossil fuels, it is essential that high volume, high quality manufacturing technologies are developed in parallel with the materials and designs for MEAs, stacks, and the other stack components, which is currently not the case. There are currently three main barriers to the development of high volume fuel cell manufacturing. First, the current practice involving extensive testing and burn-in of components and stacks will not allow the industry to achieve the necessary cost targets and throughput for stacks, components, and systems. Second, for the current process used to press low-temperature (e.g. Nafion[®]) MEAs used in both PEMFCs and direct methanol fuel cells, it is common to thermally press for as long as 1½-5 minutes. Even the pressing process for high-temperature (polybenzimidazole, or PBI) MEAs, while much shorter than for Nafion[®]-based MEAs at about one minute, is still too long for high volume manufacture. Third is the variability of MEA performance. The component materials, including gas diffusion layer or gas diffusion electrode (GDE), membranes or catalyst-coated membrane, and gasketing materials all exhibit variations in key properties such as thickness, porosity, catalyst loading, and water or acid content and concentration. Yet, it is common practice to employ a fixed combination of pressing process parameter values (time, temperature and pressure), regardless of these variations. As a result, MEAs exhibit variations in physical and performance related properties.

The research being conducted in this project will help reduce all three of these barriers by reducing the unit process cycle time for MEA pressing by the use of ultrasonic sealing, and by minimizing the variability in performance of MEAs produced using adaptive process control. This will in turn help lead to the reduction or elimination of the practice of burn-in testing of fuel cell stacks. All of these benefits will contribute to a reduction in manufacturing costs for MEAs.

Approach

The current state of practice in MEA manufacturing calls for the application of fixed pressing process parameters (time, temperature, and pressure), even though there are significant variations in incoming material properties of the membrane and electrodes including thickness, mechanical properties, and acid/water content. MEA manufacturers need to better understand the relationships among those

incoming material properties, the manufacturing process parameters, the resulting MEA physical and electrochemical properties, and the eventual electrical performance of the MEA in a stack.

We plan to address the problems associated with different methods of pressing high-temperature MEAs, specifically PBI with phosphoric acid as the electrolyte, by applying APC techniques and ultrasonics, and pressing low-temperature MEAs, specifically Nafion[®]-based, by applying ultrasonics. Through extensive experimentation and testing, we will develop analytical and empirical models of the relationships among incoming component material properties, the manufacturing process parameters, the resulting MEA properties, and the performance of the MEA in a stack. With the knowledge gained and new hardware designs, we will then attempt to identify one or more key properties (e.g., alternating current [AC] impedance, electrochemical capacitance) of the MEA that can be measured in situ during the thermal or ultrasonic pressing process, and then correlate these properties to the eventual physical and electrochemical performance of the MEA in a stack. If we are successful in identifying such an in situ measurement(s), adaptive control algorithms along with integrated process parameter and MEA performance sensing capabilities will be developed to allow us to vary the thermal and ultrasonic pressing process parameters in real time in order to achieve optimal uniformity of MEA performance.

We anticipate that the APC and processing techniques being investigated can be applied equally well, with certain modifications, to the pressing of both high-temperature and low-temperature MEAs, although the focus of this work to date has been on the former because of our extensive experience with these materials and the enhanced performance they offer (e.g., high operating temperature, no water management issues, high CO and H₂S tolerance). Our research is not application specific as the results may be applied to a broad range of fuel cell applications.

Results

APC: The application of APC to the experimental manufacturing of high-temperature PEMFCs has been an on-going effort. Experiments have been conducted to determine the best sensing method to correlate real-time electrical characteristics to eventual performance for MEAs made by thermal pressing. Using in situ alternating current (AC) impedance measurements, we are able to determine when the electrochemical cell has been formed by observing the drastic change in reactance. Our experimentation points to this change, specifically when the impedance reaches a minimum, as being the indicator of the completion of the manufacturing process.

In our current work, we apply the instrumentation method to our manufacturing process and complete the cycle when the impedance (sensed with a 1 kHz milliohmmeter) becomes a minimum. In preliminary tests,

we have found that the cycle time is reduced significantly. Our continuing experimentation will determine how much of an improvement will be made to the uniformity of performance of the cells produced using this method.

MEA Performance Evaluation Via Stack Testing: High-temperature MEAs (with 50 cm² active area) produced using APC and ultrasonics will be tested in single cell test fixtures and the performance of the MEAs will be compared to those tested during the Phase I experimentation. MEAs will also be tested in short stacks of 5 and 10 cells to determine cell to cell performance variations (e.g., voltage, temperature). Uniformity of MEAs produced by thermal pressing with APC and by ultrasonics will be compared to those produced by thermal pressing alone.

FIGURE 1. Fuel cell stack for testing 50 cm² MEAs produced using thermal pressing, thermal pressing with APC, and ultrasonics.

We have completed the design and fabrication of the stack that will be used for this investigation, as shown in Figure 1. It is be highly instrumented so that we will be able to identify individual cell performance (impedance, voltage, temperature) and also stack performance.

A serious experimental issue that was identified and corrected involved leaching of phosphoric acid into the porous graphite bipolar plates during testing. The solution was to procure POCO graphite plates that are first machined and then subjected to a post surface sintering process to completely seal surfaces.

The current experimental schedule will test single baseline MEAs (i.e. made by thermal pressing only), then a 5-cell stack, and finally a 10-cell stack test to validate the hardware. After stack performance is validated, the performance of thermally bonded MEAs with APC and ultrasonic MEAs will be tested in stacks.

Large-Scale MEA Testing: Tooling for thermal and ultrasonically bonding large scale MEAs has been designed, built and tested. The ultrasonic and thermal press tooling including registration fixtures is shown in Figures 2a and 2b, respectively. An MEA with 140 cm² active area was specially designed for this task, because the size is similar to those used in automotive applications and it was the maximum size that could be accommodated by ultrasonic horns commercially available from Branson Ultrasonics Corporation, a project collaborator. Laser cutting fixtures and a carrier frames were also designed and built. MEAs have already been fabricated using thermal and ultrasonic bonding. Performance testing of thermally and ultrasonically bonded large-scale MEAs are on-going.

Ultrasonic Bonding Process Optimization and Process Modeling: Optimal process parameters were determined for ultrasonic bonding of high temperature MEAs. Since heat treatment (i.e. boiling off excess water using an oven) was identified as the most significant process parameter in a previous designed experiment and statistical analysis (Phase I), all membranes were heat treated while the other process parameters – membrane thickness, anvil support backer stiffness, sealing pressure, and energy flux - were

FIGURE 2. (a) Ultrasonic tooling, (b) thermal press tooling and (c) single-cell test fixture for large-scale MEAs (140 cm²)

systematically varied in a two-level, full-factorial (2^4) experimental design with two replicates. Testing including creating a pole curve and measuring cell resistance after a 16-hour incubation period required for the hydrolysis and vaporization reactions to reach equilibrium. Specifically, current density at two voltages (0.4 and 0.6 V) and cell resistance were measured as output variables. In addition to heat treatment, process conditions for making optimal performing MEAs included low pressing pressure, low anvil support backer stiffness, and high booster amplitude based on analysis of variance. A comparison of polarization curves between the manufacturer's baseline thermally pressed MEA and an MEA fabricated with optimal ultrasonic process parameters is shown in Figure 3.

The MEA ultrasonic bonding process is being modeled using a combination of vibration and FEA theory. The vibrational model – masses coupled in series with a spring and spring/damper in parallel for each of the three layers (GDE, membrane, GDE) – currently contains six degrees of freedom. Model input is a high frequency (20 kHz) and low amplitude (20 μm) vibrational signal along with a constant preload (pressing pressure) from the ultrasonic horn. Because of the extreme ratio of the model spring stiffness to the model mass, the natural frequencies are very high. This necessitates the use of a stiff computational solver. Currently, the model is still being refined to balance model accuracy with computational time. Heat dissipated by the dampers in real time is used in a COMSOL FEA transient thermal analysis with internal heat generation at each of the MEA material interfaces (GDE/membrane $\times 2$). Because of the symmetry of the model and the fact that the heating is assumed to be uniform, the COMSOL model is now two-dimensional, rather than three-dimensional. A one-dimensional model was found not to give as clear of a visualization of the heating process.

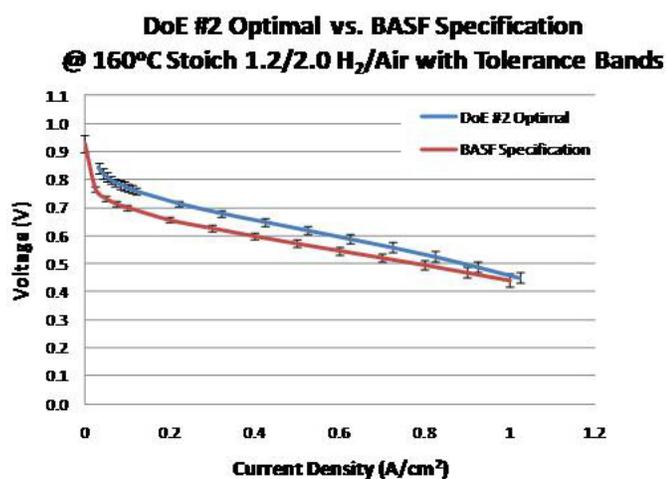

FIGURE 3. Polarization curve of optimal ultrasonically bonded MEA with superior performance as compared to the BASF specification.

Using experimentally derived stiffness and damping values for each layer of the MEA (no fudge factors), the model closely matches thermocouple temperatures measured through the MEA thickness during ultrasonic bonding.

Heat Treatment Optimization: A 2-factor, 3-level, 2-replicate design of experiment was designed for the MEAs with oven temperature and soak time as the variables. Single cell evaluation of the heat-treated MEAs was performed after an 18-hour burn-in period at 200 mA/cm² followed by polarization curve measurements at 160°C. The single cell performance of the heat-treated, ultrasonically sealed MEAs was measured along with membrane thickness and acid concentration. Statistical analysis showed that the middle and low temperature and their corresponding heat treatment duration were all significant. More importantly, heat treatment duration beyond the lowest level (15 min) provided no performance benefit.

Ultrasonic Bonding of Low Temperature MEAs: Low-temperature MEAs with 10 cm² active area have been successfully sealed using a 20 kHz ultrasonic machine and by thermal pressing. With ultrasonic bonding, the MEA is built carefully by hand, ensuring alignment between the two electrodes, on a piece of Kapton. A second layer of Kapton is placed on top of the assembly to protect the ultrasonic horn, and it is placed on a smooth anvil in the ultrasonic sealer. The ultrasonic welding setup is shown in Figure 4a. Finally, registration holes for alignment in the single cell test hardware are laser-cut into the oversized Nafion[®] membrane. An ultrasonically welded MEA is shown in Figure 4b.

Testing of the low-temperature MEAs is planned so that those that are ultrasonically bonded can be compared to thermally pressed baseline MEAs. The bonding process on the ultrasonic setup will be optimized by varying the sealing pressure and energy flux and evaluating the performance. Various techniques and “recipes” to produce thermally pressed MEAs will be explored to maximize the baseline performance.

Durability Testing of Ultrasonically Bonded MEAs: Accelerated durability testing of the high-temperature MEAs (50 cm²) was performed using test protocols designed to simulate real life operating conditions. The accelerated durability testing protocols involved fuel cell startup/shutdown, load cycling and thermal cycling processes performed over 200 hours. MEAs sealed ultrasonically with optimized process parameters exhibited excellent stability, i.e. no cell voltage degradation and minimal cell internal resistance change, during the 200-hour tests. The authors believe that the ultrasonic sealing technique combined with accelerated durability testing will be vital to the development of high volume fuel cell manufacturing

Conclusions and Future Directions

We are encouraged by the performance of ultrasonically bonded high temperature MEA performance made using

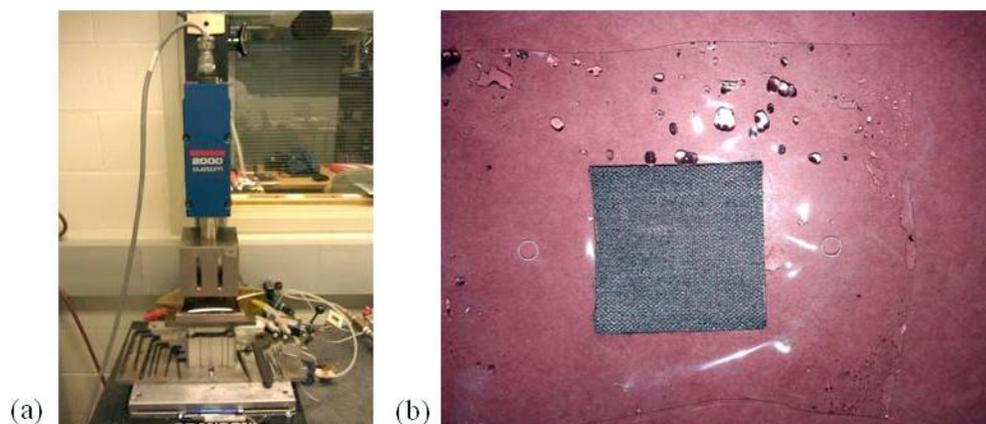

FIGURE 4. (a) Ultrasonic setup used to bond low-temperature MEAs and (b) resulting MEA after laser cutting alignment holes.

optimized process parameters based on single-cell testing after standard incubation and accelerated durability testing. Performance to date has been at least equal to baseline data provided by the manufacturer for thermally bonded MEAs. APC offers a way to minimize cycle time and improve the consistency of thermally pressed MEAs, although cycle times will still be at least an order of magnitude longer than for ultrasonic bonding. Likewise, cost model predictions based on actual experimental data include a 29% reduction by implementing APC and 90% by implementing ultrasonics. The entire research team is prepared to test the performance of 50 cm² high temperature MEAs made by standard thermal pressing, APC, and ultrasonic bonding in short stacks and monitor individual cell characteristics. We are also prepared to test and compare larger scale (140 cm²) high temperature MEAs made using the same three bonding methods. Finally, the team is prepared to compare the performance of small (10 cm²) low-temperature MEAs made by thermal pressing and ultrasonic bonding. Major activities planned for the remainder of Phase II include:

- Showing how MEAs made by thermal pressing with APC and ultrasonic bonding perform in short stacks compared to those made by conventional thermal pressing.
- Showing how the ultrasonic bonding process scales by comparing the performance of larger scale MEAs (ultrasonically and thermally bonded) to that of standard size MEAs.
- Continue refining the ultrasonic bonding models, validate with experimental data, and demonstrate how such a model would be used for process design and optimization.
- Showing how ultrasonic bonding works for low-temperature MEAs and identifying significant process parameters.

Project Start Date: October 1, 2007 Revised
Interagency Agreement (October 1, 2009)
Project End Date: October 1, 2009 Revised
Interagency Agreement (October 1, 2011)

- **Milestone 13:** Complete development of standards for metrology of PEM fuel cells. (4Q, 2010)

FY 2011 Accomplishments

- Implemented performance testing protocol improvements to better highlight performance issues (1/2011).
- Quantified baseline repeatability of performance testing as a metric for determining what differences are statistically significant (1/2011).
- Completed initial round of performance testing on all experimental cathode plates at 25 psig back pressure which showed some significant performance differences (2/2011).
- Expanded protocol to include testing at ambient back pressure (as a result of a 2010 Annual Merit Review meeting reviewer comment) using the two worst performing experimental plates #3 and #7 (3/2011):
 - This testing showed that the performance differences still existed, regardless of back pressure.
 - The best performing experimental cathode plate #5 was to be tested under this extended protocol but broke during assembly (fabrication of replacement in process).

Fiscal Year (FY) 2011 Objectives

Develop a pre-competitive knowledge base of engineering data relating fuel cell performance variation to bipolar plate manufacturing process parameters and dimensional variability.

Technical Barriers

This project addresses the following technical barriers from the Manufacturing R&D section of the Fuel Cell Technologies Program Multi-Year Research, Development and Demonstration Plan:

- (B) Lack of High-Speed Bipolar Plate Manufacturing Processes
- (F) Low Levels of Quality Control and Inflexible Processes

Contribution to Achievement of DOE Manufacturing R&D Milestones

This project will contribute to achievement of the following DOE milestones from the Manufacturing R&D section of the Fuel Cell Technologies Program Multi-Year Research, Development and Demonstration Plan:

Introduction

Based on a workshop organized by the Center of Automobile Research and NIST in December 2004; industry bipolar plate manufacturers identified a need for engineering data that relates geometric bipolar plate tolerances to fuel cell performance. This need is in response to pressure from fuel cell designers to produce lower cost plates, as such, plate manufacturers are being forced to consider potential quality related trade-offs to achieve desired cost targets. To justify these trade-offs, manufacturers are questioning the relevance of stated tolerances on dimensional features of bipolar plates; they expressed a desire for published engineering data relating performance and dimensional quality of the plates that can be used as reference when making these decisions. In response to the identified need, this project was conceived in 2004 and partially funded through the NIST Advanced Technology Program (ATP) Intramural Competition for a period of three years (FY 2005-FY 2007). The ATP funding was also intended to aid NIST with the development and validation of a single-cell testing laboratory. In 2008, funding was provided through DOE in an attempt to bring this project to a successful completion by the end of FY 2008.

To date, the reference single-cell design has been selected, the fabrication and dimensional verification of

all experimental plates has been completed according to a statistically based design-of-experiments. All that remains to be completed is the repeatability testing to verify the initial performance test results, the fabrication, dimensional verification, and performance testing of replacement cathode plate #5C at the various back pressures, and the analysis of the performance testing along with the derivation of conclusions based on the full-factorial design of experiments.

Polymer Electrolyte Membrane (PEM) Fuel Cell

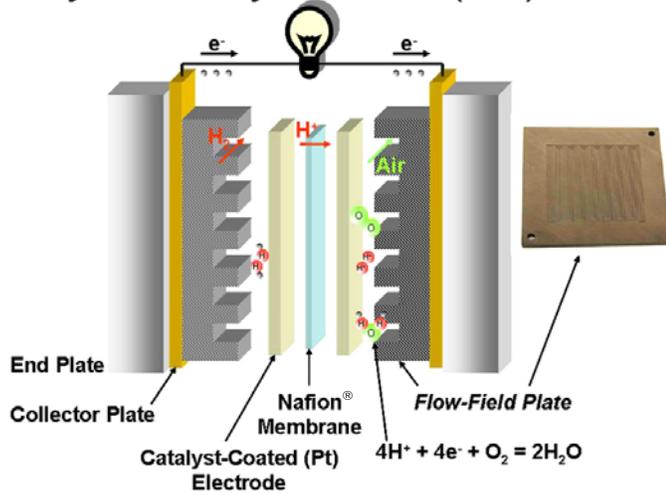

FIGURE 1. Concept - Reference Single-Cell and NIST Fabricated Cathode Flow Field Plates

Approach

Using a statistically based design-of-experiments (Figure 1), fabricate experimental “cathode” side flow field plates with various well defined combinations of flow field channel dimensional variations (Figure 2); then through single-cell fuel cell performance testing using a well defined protocol, quantify the performance effects, if any, and correlate these results into required dimensional fabrication tolerance levels.

Results

The initial performance testing last year, as reported, revealed some very necessary modifications to the protocol.

FIGURE 2. Design of Experiment 2⁴⁻¹ Fractional Factorial Design...4 Parameters, 2 Levels, and Replicate Center Point

The most significant was that the same catalyst coated membrane (CCM) could not be reused from plate-to-plate thus a new CCM had to be used. To increase the likelihood of acceptable repeatability, we ensured that all the CCMs came from the same batch. As any particular level of repeatability cannot be assumed, we then performed multiple voltage-current (V-I) curves using the same plate configuration with a different CCM. The results as shown in Figure 3 demonstrate repeatability commensurate with previous high-level single cell testing round robins where multiple labs tested the same single cell assembly, thus we concluded we have attained the desired benchmark repeatability.

Two more recent modifications were identified to better highlight the impact of the intentional dimensional variabilities on performance in the mass transport region. To promote the onset of mass transport we: (1) reduced the anode and cathode platinum loadings from 0.2/0.4 mg/cm² respectively to 0.1/0.2 mg/cm² and (2) increased the cathode utilization from 50% to 71%. These modifications proved effective, thus we completed the initial V-I curves for all 10 experimental cathode plates as shown in Figure 4. These data were collected applying 25 psig backpressure at the outlets as originally defined in our protocol.

After receiving the reviewers' comments from the 2010 DOE Annual Merit Review meeting in June 2010 we added some additional testing to address a specific reviewer's concern that the backpressure chosen was not within realistic operating conditions. To address this concern, we selected cathode plates #3C, #5C, and #7C which represent the best and worst performers for repeated testing at an intermediate backpressure and ambient. The results for plates #3C and #7C are shown in Figure 5. Unfortunately plate #5C, the best performer, broke during assembly due to a misalignment of one of the sealing gaskets.

Initial VIR curves for all plates @ 80°C, 100% & 50% RH, 25 psig

RH - relative humidity

FIGURE 4. Initial Polarization Data for All 10 Experimental Cathode Plates

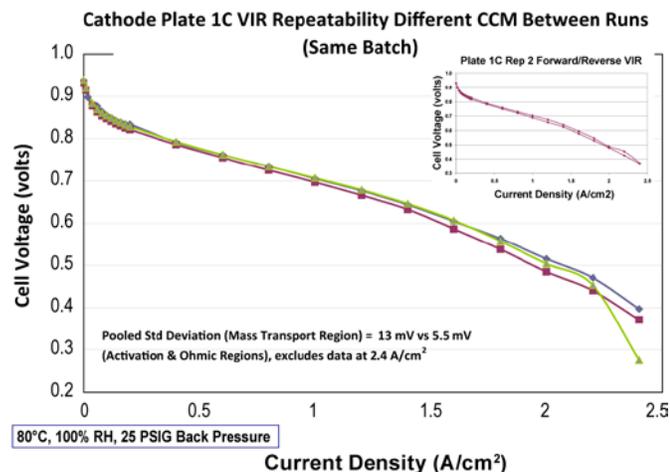

FIGURE 3. Polarization Curve Repeatability with CCM Change-Out between Runs

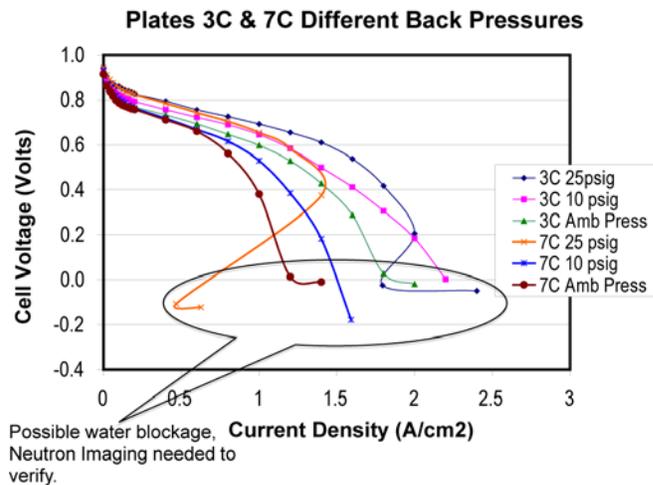

FIGURE 5. Polarization Testing of Select Plates at Different Back Pressures

As expected the polarization curves shifted lower with lower back pressures, however the plate-to-plate performance differences remained. A replacement for plate #5C is currently being fabricated.

Conclusions

- Protocol revisions were carefully derived and meticulously verified, thus the repeatability objectives were achieved and were better than expected.
- To this point testing shows that the intentional dimensional variability at the magnitudes chosen does affect the performance significantly.
- Additional testing, to this point, clearly demonstrates that these performance differences exist regardless of the outlet back pressure.

Future Direction

Project Deliverables

- NIST will fabricate and dimensionally verify a replacement experimental cathode plate #5C.
- Using the replacement #5C plate, LANL will repeat the initial polarization curve at 25 psig backpressure to ensure the results correlate with those of the original plate and complete the polarization curves at the intermediate and ambient backpressures.
- With the assistance of the NIST Statistical Engineering Division, correlate the polarization curve results with the design-of-experiments to elucidate which parameters or combination of parameters have the biggest impact on performance.
- Publish results.

Optional Deliverables (contingent on funding availability through either NIST or DOE)

The addition of the optional deliverables is to dispel the hypothesis that the water management issues are due to the serpentine flow field design or more specifically water being trapped in the turns rather than due to the dimensional perturbations. This concern was raised during a voluntary presentation we gave to the FreedomCAR Technical Team in March of 2011. All experimental plates use the same flow field design and perturbations do not exist in the turns therefore it is believed that repeatable performance differences are due to the perturbations.

- NIST will fabricate and dimensionally verify a subset of the experimental cathode flow field designs into a metallic flow field plate compatible with the LANL 50 cm² single cell designed for neutron imaging.
- LANL will perform the polarization protocol at the NIST Neutron Center for Neutron Imaging in order to identify where exactly within the flow field the mass transport issues are occurring.

Suggested Future Work

- Repeat experiments using a parallel flow field design in a metallic plate using the more critical parameters identified in this study along with other parameters, such as, surface finish not previously tested.

Disclaimer

Certain commercial equipment, instruments, or materials are identified in this paper in order to specify the experimental procedure adequately. Such identification is not intended to imply recommendation or endorsement by the National Institute of Standards and Technology, nor is it intended to imply that the materials or equipment identified are necessarily the best available for the purpose.

section of the Fuel Cell Technologies Program Multi-Year Research, Development and Demonstration Plan (Section 3.5.7):

- Develop continuous in-line measurement for MEA fabrication. (4Q, 2012)
- Establish models to predict the effect of manufacturing variations on MEA performance. (4Q, 2013)

This project addresses coating speed and uniformity of GDEs, a critical component for MEA fabrication. One sub-task is to develop a continuous X-ray fluorescence analyzer that directly measures catalyst deposition level and distribution on rolled goods, ultimately guiding improvements in through-put and uniformity. This sub-task directly contributes to the fourth quarter 2012 goal for in-line measurement. Another sub-task is to develop models that predict the effect of manufacturing variations in catalyst distribution and porosity in GDEs, and relate these variations as six-sigma limits for a component specification. The establishment of a model that predicts MEA performance based on manufacturing variations in GDEs contributes to improving the quality of the component as well as achieving the fourth quarter 2013 DOE milestone above.

Fiscal Year (FY) 2011 Objectives

- Reduce cost in fabricating gas diffusion electrodes (GDEs) through the introduction of high speed coating technology, with a focus on materials used for the high temperature membrane electrode assemblies (MEAs) that are used in combined heat and power (CHP) generation.
- Relate manufacturing variations to actual fuel cell performance in order to establish a cost-effective product specification.
- Develop advanced quality control methods to guide realization of these two objectives.

Technical Barriers

This project addresses the following technical barriers from the Manufacturing R&D section of the Fuel Cell Technologies Program Multi-Year Research, Development and Demonstration Plan (Section 3.5):

- (A) Lack of High Volume Membrane Electrode Assembly (MEA) Processes
- (F) Low Levels of Quality Control and Inflexible Processes.

This project will contribute to achievement of the following DOE milestones from the Manufacturing R&D

FY 2011 Accomplishments

- Reduced labor cost to manufacture GDE by 50%.
- Improved cathode catalyst utilization by ~25% through 20 mV gain in performance.
- Met key milestone of doubling throughput for GDE at production scale.
- Coated carbon cloth GDEs at >2X width – timing is ahead of milestone plan.
- Demonstrated pilot-scale fabrication of GDEs on a lower cost non-woven web.

Introduction

The basis of this project is to create GDEs at a far lower cost than those currently available. GDEs are critical components of membrane electrode assemblies and represent the highest cost subcomponent of the MEA. Cost reduction will be accomplished through development of a higher throughput coating process, modeling the impact of defects due to the higher speed process, and overcoming these limitations and providing a six-sigma manufacturing specification that relates performance to defects. The main focus of the effort is creating next-generation inks through

advanced additives and processing methodologies. As part of our approach, we will also develop on-line quality control methods such as determination of platinum concentration and distribution during the coating process. The on-line mapping of platinum will guide the ink development process and provide feedback on uniformity.

For this reporting period we significantly advanced our understanding of the inherent limitations of suspensions of carbon black or carbon black catalysts mixed with a hydrophobic binder. The use of a hydrophobic binder is critical to create GDEs for high temperature MEAs. Through this project's understanding we developed improved inks that can be made more concentrated and thus reduce the number of applications needed per pass. These new inks also used substantially less time to prepare, and afforded greater utilization of the catalyst once in the MEA, improving performance. We also began to apply the ink development sequence to lower non-woven carbon paper cost.

Approach

GDEs are comprised of a gas diffusion layer coated with catalyst. The gas diffusion layer is simply carbon cloth or a non-woven carbon that has been coated with carbon black and serves as a current collector for the catalyst. For both the carbon black and catalyst, a hydrophobic binder is added to achieve critical porosity and hydrophobicity in the final structure. Of the carbon black, catalyst, or hydrophobic binder none are highly soluble in aqueous solutions. Aqueous solutions must be used as solvents since the use of organic solvents with a highly active catalyst is too dangerous in a production environment. Also, the hydrophobic binder is shear-sensitive, meaning it becomes less stable when pumped or subjected to shear forces in the coating applicator. Thus, the challenge in this project is overcoming the inherent physical limitations in these materials through advanced formulations and processing.

Our approach to solving this challenge begins with identifying key quality GDE metrics that relate directly to ink performance, develop an understanding of the forces behind ink stability, and introduce solution measurement methods that relate ink performance to the quality metrics. With more stable ink formulations, we anticipate being able to coat longer and wider webs at higher speeds. If an ink can be made more concentrated and remain stable we can use less application passes and save cost. The ink development process is supplemented by two other activities that ultimately lead to lower cost GDEs. We will develop a model that will predict the impact of manufacturing variations on MEA performance, and use this model to determine the level of coating quality needed to maintain consistent current and voltage. Also, we will create on-line instruments to lead development of more precise coating processes.

In this period, we combined next generation stabilizing additives with high energy dispersion techniques to greatly improve the inks, and scaled these through to the production coater.

Results

Microporous Layer

One significant problem was posed by the hydrophobic carbon used in the microporous layer (MPL). When benchmark inks and additives are used, this ink became less viscous as the shear rate increases. This shear-thinning behavior indicates strong particle-particle interactions and is shown as the trace labeled “baseline, low solids” in Figure 1. The shear-thinning becomes worse when we increased the solid content of the ink – desirable to reduce number of coating passes (see trace “baseline, high solids”). High shear-thinning indicates instability for the formulation as well as higher potential for non-uniformity under the shear forces of the applicator. By using a combination of additives and a high energy preparation method, we were able to create inks for the MPL that are Newtonian, that is, shear insensitive over a wide range. See the Figure 1 trace labeled “improved, highest solids.” Note the solid content of this ink enabled >55% reduction in number of application passes needed, as well as a 50% reduction in time to prepare the ink. We scaled this MPL ink formulation to the production coater and demonstrated full width coating ahead of plan.

Cathode Electrode Layer

Last year we reported improvements in the cathode catalyst ink formulation that decreased the number of coating defects due to agglomeration and held potential to reduce the number of application passes by 30% when using our pilot-scale coater. We have now identified an

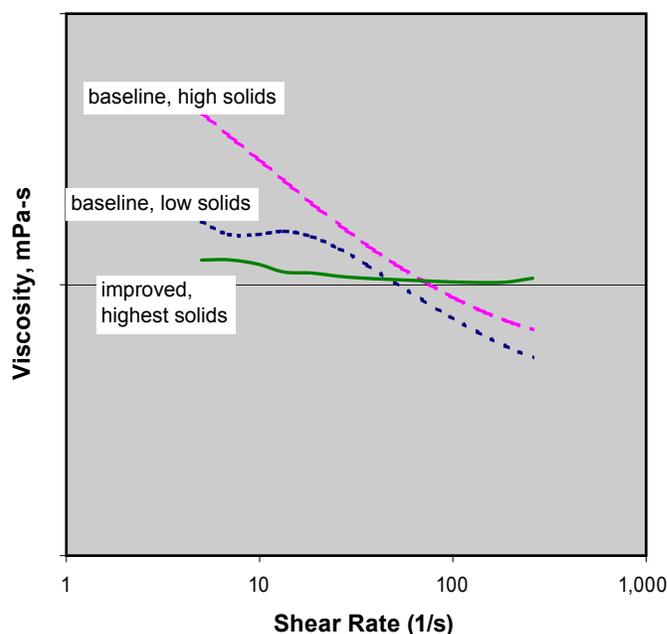

FIGURE 1. Viscosity vs. shear rate for three different ink formulations: baseline (low solids), baseline (high solids), and improved (highest solids).

improved additive system (several additives that work in concert) that not only stabilize higher concentrations of inks, but completely eliminated a labor-intensive step in ink making. We have scaled this improvement to our production scale coater as well as demonstrated a savings of >60% in labor hours for ink making and decrease in number of coating passes by 40%. Furthermore, these inks have shown a remarkable improvement in cathode performance as evidenced in Figure 2. We attribute the ~20 mV gain over baseline to an increase in platinum utilization through enhanced uniformity by 25%.

Anode Electrode Layer

A key difference between the anode and cathode electrodes is the catalyst. The cathode employs an alloy to facilitate oxygen reduction. Since the MEAs being developed under this project operate between 160°–180°C, they are highly tolerant to carbon monoxide (CO) and operate well at 1%-2% CO using only a pure platinum catalyst. Throughout this project we have adhered to the ink additive selection rules that are summarized as follows: select compounds that stabilize the ink components, leave no or minimal residue in the MPL or electrode layers, and do not disturb the intended porosity and hydrophobicity profiles. The anode catalyst is sufficiently different than the cathode that not only was a modified suite of additives employed, but extensive efforts were needed to develop a removal sequence to both minimize residues and preserve optimal hydrophobicity in the electrode layer. We were successful in developing an anode ink that also eliminated the labor-intensive step of the cathode, and also reduced ink

preparation labor by 50% and decreased the time for coating passes by 40%. This ink has been scaled through to the full production coating machine.

Conversion of Lower Cost Substrates

A second major focus of this project is to develop lower cost substrates into GDEs. Non-woven carbon fiber materials (“carbon paper”) are believed to be ~30% lower in cost compared to the carbon cloth at higher volumes. The porosity, hydrophobicity, and absorption properties of the carbon papers are totally different than carbon cloth, and we had to develop an entirely new class of inks for the MPL, anode electrode layer, and cathode electrode layer. Although in the pilot-scale with limited coating lengths, we have established good progress. Figure 3 shows our status with a MPL plus cathode catalyst layer compared to the benchmark carbon cloth performance in hydrogen/air at 160°C. The inks developed for the carbon paper have been able to preserve the higher solid content of the carbon cloth inks and reduced number of application passes.

Conclusions and Future Directions

Through last year’s foundation in understanding principle mechanisms behind ink destabilization and additive selection, we have been able to significantly improve the coatings of MPLs, anode catalyst layers, and cathode catalyst layers. While the objective of this project is to decrease cost by increasing throughput, we have also improved the overall process by decreasing the labor content for ink preparation by ~50%. We have scaled these new formulations to a full-

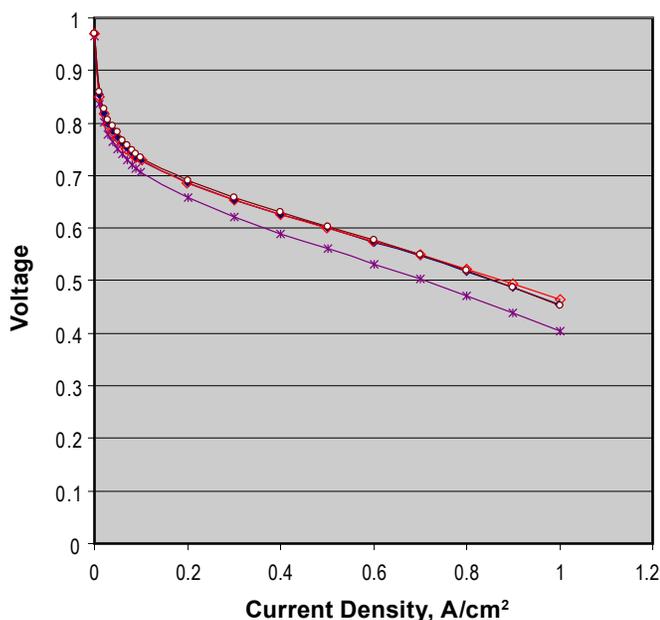

FIGURE 2. Voltage vs. current plot of baseline high temperature MEA vs. same with improved cathode catalyst layer at pilot and production coating scales. 160°C, H₂/air, 1.2/2, ambient pressure.

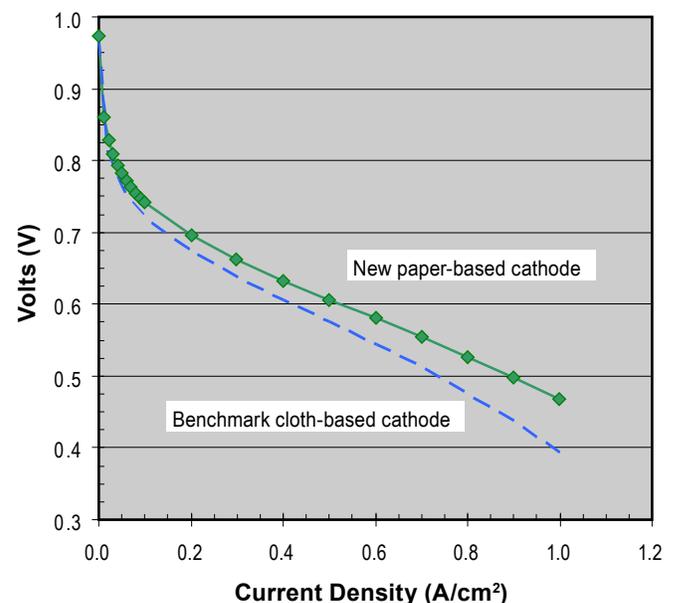

FIGURE 3. Voltage vs. current plot of baseline high temperature MEA vs. same made with carbon paper substrate at pilot coating scales. 160°C, H₂/air, 1.2/2, ambient pressure.

scale production coater, and achieved our key milestone of doubling throughput. A fringe benefit of the more uniform structures created by this approach is an improvement in performance by ~20 mV, inferring an increase in catalyst utilization by around 25%. Pilot-scale results on low cost non-woven substrates are encouraging and show a path for further decrease of costs. Advances in this project are being transitioned to our current production techniques with a direct immediate impact on component cost.

Upcoming Focus

1. Develop full-width carbon cloth coating to gain another 2X throughput factor.
2. Qualify current formulations on full-width, full length production coating trials.
3. Develop formulations for non-woven carbon paper for a further reduction in cost: demonstrate on production coater.

Project End Date: Project continuation and
direction determined annually by DOE

- Developed printhead control algorithms suitable for printing of thin films.
- Thin film printing station constructed and has undergone initial testing and calibration. Will be brought on line soon.
- Demonstrated that MEAs prepared by inkjet fabrication have comparable performance to commercially available MEAs. Needs optimization.

Introduction

One of the primary DOE goals for use of proton exchange membrane fuel cells (PEMFCs) as power plants in transportation includes the reduction of manufacturing costs to below \$30/kW. Today's low-volume, actual cost is greater than \$1,000/kW and the high-volume manufacturing cost, based upon current manufacturing process, is extrapolated to be less than \$300/kW [1-3]. New manufacturing processes are needed and must be able to:

- Adapt to the transition from low-volume specialty to the high-volume automotive markets,
- Rapidly incorporate advances in PEMFC technology, and
- Accommodate both small and large production runs.

Fiscal Year (FY) 2011 Objectives

- Evaluate membrane electrode assembly (MEA) fabrication process and compare catalyst printing and coating process.
- Critically evaluate inkjet or "drop-on-demand" printing technology to meet the criteria specified in the above objective.

Technical Barriers

This project addresses the following technical barriers from the Manufacturing R&D section (3.5.5) of the Fuel Cell Technologies Program Multi-Year Research, Development and Demonstration Plan:

- (A) Lack of High-Volume Membrane Electrode Assembly (MEA) Processes
- (F) Low Levels of Quality Control and Inflexible Processes

Contribution to Achievement of DOE Manufacturing R&D Milestones

This project will contribute to achievement of the following DOE milestones from the Manufacturing R&D section of the Fuel Cell Technologies Program Multi-Year Research, Development and Demonstration Plan:

- Develop fabrication and assembly processes for polymer electrolyte membrane automotive fuel cell that meets cost of \$30/kW. (4Q, 2015)

FY 2011 Accomplishments

- Technical analysis of printing coating fabrication process completed and report to DOE in final draft.

Approach

Digital fabrication, in combination with unique catalyst-layer ink formulations, will eliminate or simplify many of the currently necessary, but slow and cumbersome, pre- and post-deposition processing steps. In earlier work [4] we have shown that for the digital fabrication process that:

- No hot-press/lamination is needed to ensure catalyst layer adhesion to the membrane,
- Wastage of membrane and catalyst materials are minimized,
- Catalyst utilization can be enhanced with XY and Z gradations in composition,
- The hydrogen form of the membrane can be directly used and no chemical transformation to the sodium form is needed, and
- Digital fabrication is highly adaptable in an evolving technology scenario.

It is the goal of the project to understand fully the implications of digital fabrication on processing, design prototype digital fabrication facilities to test production methods, provide a basis for quantitative cost comparison with current fabrication technology, integrate the fabrication with the rest of PEMFC stack assembly and develop

design criteria for a pilot plant manufacturing line based upon digital fabrication. The project digital-fabrication approach will lead to a higher quality product with improved performance, fabricated by a simpler and more cost-effective production process. Digital fabrication will be an agile and versatile means of production, and will provide a viable route to meeting DOE production targets for PEMFC-based power plants.

Results

Analysis of Catalyst Layer Printing and Coating Technologies

A review of the advantages and disadvantages of printing and coating technologies in the fabrication of catalyst coated membranes was conducted [5-7]. This included direct contact methods such as offset and flexographic printing, ink spreading systems such as the myriad forms of roll coating, doctor blading and slot die coating and Gravure printing. Noncontact methods include aerosol and airless spraying as well as piezoelectric and thermal inkjet processes were also considered.

Process deposition speed is not the only requirement to be considered in the manufacturing process and may be of minor importance especially for an emerging industry. The criteria for evaluation of the catalyst coating process were 1) ink development complexity, 2) suitability to long, medium and short production runs, 3) coating speed and adaptability, 4) ability “patch” coat, 5) ability to grade catalyst layer composition, and 6) coating thickness and variability.

In comparison of the various techniques slot die, Gravure and inkjet printing provide the best characteristics for at least some scalability in comparison to the other techniques discussed:

- Each of these three methods conserves expensive catalyst and membrane material.
- Each has highly variable speeds although slot die coating quality has a stronger dependence on speed.
- Inkjet coating is easier to integrate into a process line whereas slot die and Gravure process will constrain if not dominate the process line design.
- Slot die coating cannot be used to grade coatings.
- Slot die coating provides a relatively thick single pass coating.
- Gravure printing is not well suited to lab scale and small job scale production.
- A combination of digital and continuous inkjet printing provides scalability from the lab- to automotive-scale.

Requirements of Thin Film Inkjet Printing

Inkjet printing technology is focused at printing words or images for which surface reflectivity is the most important

physical criteria. Further continuous films are not required and half toning and dithering are used to achieve color and gray scale but often leave distinct significant portions of the substrate without an ink deposit. The properties are not compatible with thin film structures that must have uniform or graded but continuous structure over many centimeters. Further a printed layer of a given composition may have to interface with an under or over lying layer of different composition.

To address this issue we developed a unique print algorithm that was implemented for the 2x25 printhead pattern of a HP-26 print cartridge. The algorithm ensures that:

- All jets are used evenly to prevent clogging,
- No single pixel is printed more than once,
- The jet patterns are “woven” to prevent vertical and horizontal banding,
- The algorithm can be adapted to a particular printhead jet pattern, and
- Successive prints can be offset slightly to ensure uniformity.

A printer was fabricated to allow testing of printing parameters in future work – see the following. The printer was based upon two HP-26 inkjet cartridges and is capable of depositing up to four inks although only one ink systems have been tested to date. The system uses a Microchip PIC24J256GB110 microprocessor to control XYZ table movements and individual jet firing and communication with a universal serial bus (USB) storage device. MATLAB was used to implement the algorithm discussed above, and convolute the print pattern with an image pattern. The file output from this is stored on the USB device in a simple form ready for microprocessor implementation. Figure 1 shows an approximately 10 μm thick film of yttria-stabilized zirconia (YSZ) printed with this experimental printer. YSZ suspensions were used for initial testing as the suspensions are very stable and the average particle size is two orders of magnitude smaller than the jet orifice size.

We previously had worked closely with Hewlett-Packard and used their experimental print facilities for initial work. However we did not have permission to sufficiently modify those instruments to allow close control of humidity and substrate temperature. The new printer, although less sophisticated, will allow better examination of the printing process.

Printhead Reliability

Printheads after many thousands (if not millions) of firing cycles are subject to clogging by the presence of minute quantities of large particles. We conducted two tests using identical printheads with 20 and 28 μm diameter jets. The 20 μm jets failed due to clogging after only a few hundred cycles while the 28 μm jets did not fail during

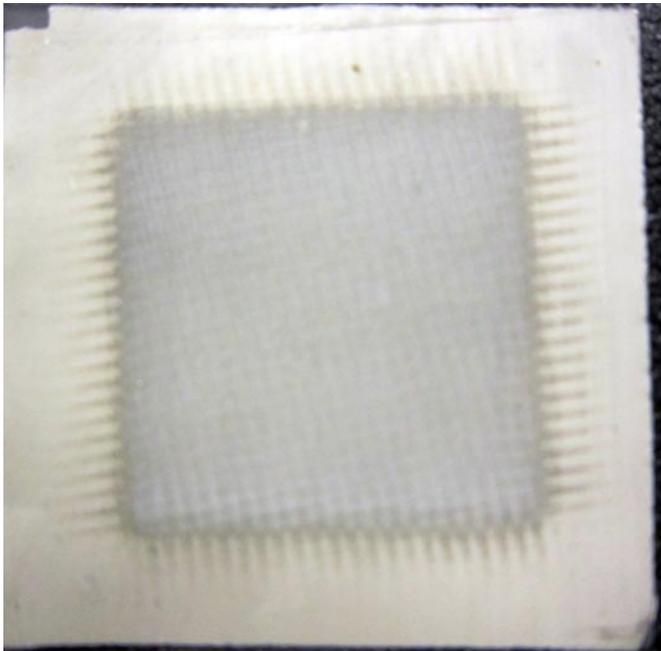

FIGURE 1. Photograph of an Approximately 10 μm Thick YSZ Film

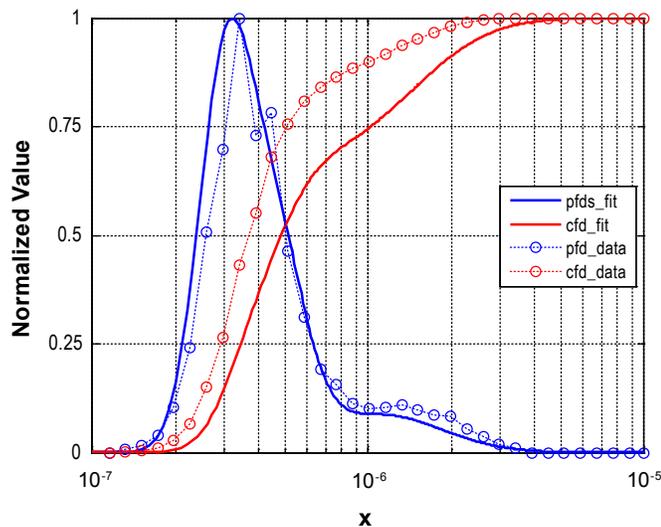

FIGURE 2. Normalized Particle Size Distribution and Log Normal Fits of Catalyst Inks

experimental use. Figure 2 shows the normalized particle size distribution of our catalyst inks as well as the log normal fits to these data. Note the presence of a large shoulder at about 1.5 μm off the main peak at about 0.3 μm. These peaks are much smaller than the 20 and 28 μm jet diameters yet the 20 μm jets clogged while the 28 μm jets did not clog. The log normal fit to the data was used to estimate the distribution of very large particles in a suspension that could not in reality be detected by particle size analysis. As shown in Figure 3, the probability of clogging after 1,000 fires is

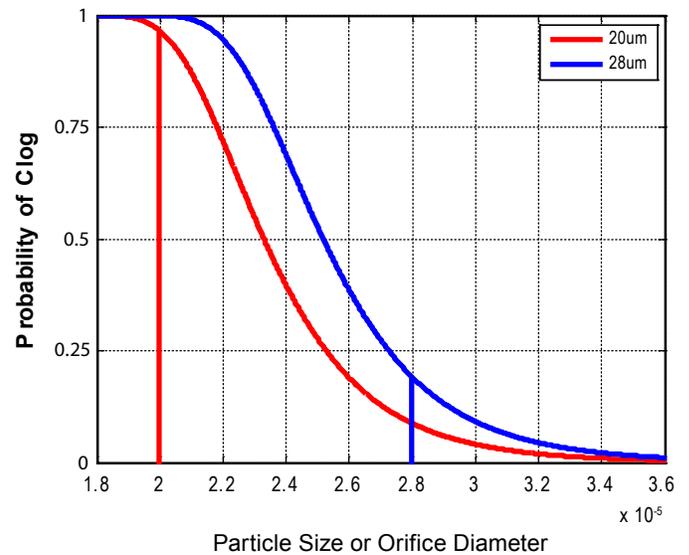

FIGURE 3. Probability of Clogging after 1,000 Fires for 20 μm and 28 μm Jet Orifices

98% for a 20 μm jet while that for a 28 μm jet is only 25%. By eliminating the large shoulder through appropriate filtering, the probability of clogging can be substantially reduced but this work demonstrates the need to carefully consider ink stability and to prevent particle aggregation before use.

Comparison of Commercial and Inkjet Printed Electrodes

To realistically compare catalyst coated membranes fabricated by different processes we adapted standard performance tests into a series of 15 electrochemical tests that allowed comparison of performance under a wide variety of conditions including back pressure up to 15 psig, O₂ vs. air, different cathode and anode relative humidities and stoichiometries. Shown in Figure 4 are current-voltage curves, taken with air at the cathode and at 0 and 15 psig backpressure, for a digitally fabricated MEA and one purchased from Ion Power. Both had 0.2 mg/cm² of platinum. The Ion Power electrode was distinctly better but not so much better that the difference can be attributed to the fabrication method. It may well be that difference in electrode composition may be more important. We note that, with O₂ at the cathode, the inkjet fabricated electrodes outperformed the Ion Power electrodes.

Conclusions

- Technical analysis of printing and coating processes completed and report in final draft.
- Defined algorithms suitable for printing of thin films.
- Thin film printing station constructed and has undergone initial testing and calibration. Will be brought on line soon.

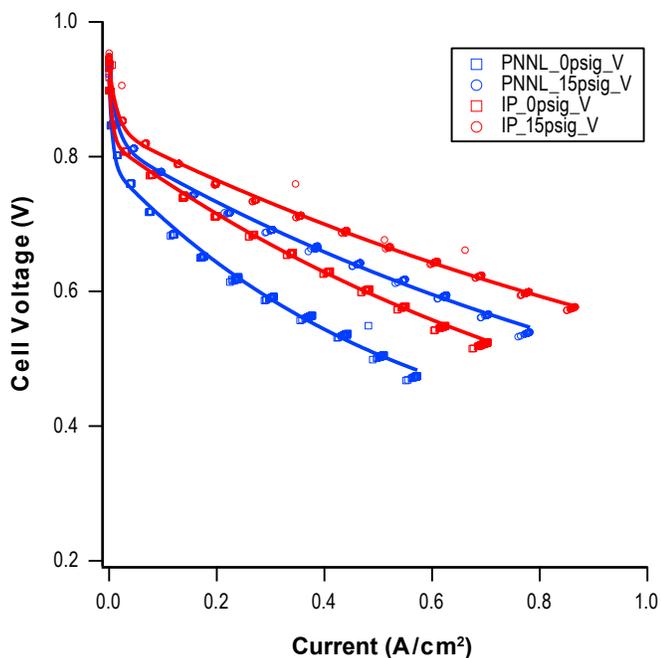

FIGURE 4. Comparison of in-house digitally fabricated MEAs with commercially produced MEAs. Results shown are for air at the cathode and at 0 and 15 PSIG backpressure.

- Demonstrated that MEAs prepared by inkjet fabrication have comparable performance to commercially available MEAs. Needs optimization.

Future Directions

- Develop catalyst-compatible inks that prevent particle aggregation and jet clogging.
- Optimize ink composition (ionomer, carbon, catalyst ratio).

- Determine optimal printing conditions - relative humidity, substrate temperature.
- Quantify relationship of substrate wettability to thin film uniformity.
- Determine maximum single pass thickness.
- Quantify development needs for continuous inkjet fabrication.

Project Start Date: September 26, 2008

Project End Date: March 31, 2012

Technologies Program Multi-Year Research, Development and Demonstration Plan:

- (G) High-Cost Carbon Fiber
- (H) Lack of Carbon Fiber Fabrication Techniques for Conformable Tanks

Contribution to Achievement of DOE Manufacturing R&D Milestones

This project will contribute to achieving Milestone 24 from the Manufacturing R&D section of the Fuel Cell Technologies Program Multi-Year Research, Development and Demonstration Plan:

- Develop fabrication and assembly processes for high-pressure hydrogen storage technologies that can achieve a cost of \$/kWh. (4Q, 2015)

FY 2011 Accomplishments

- Passed burst test with Vessel 7 and reduced 22.9% of carbon fiber from baseline vessel.
- Completed cost model for hybrid process according to the latest vessel design.
- Characterized polymer materials in high-pressure hydrogen environment.
- Completed the design, build, and integration of the next-generation AFP head.
- Down-selected a lower-cost and lower-strength carbon fiber suitable for vessel outer layers.

Fiscal Year (FY) 2011 Objectives

Develop new methods for manufacturing Type IV pressure vessels for hydrogen storage with the objective of lowering the overall product cost by:

- Optimizing composite usage through combining traditional filament winding (FW) and advanced fiber placement (AFP) techniques.
- Exploring the usage of alternative fibers on the outer layers of the FW process.
- Building economic and analytical models capable of evaluating FW and AFP processes including manufacturing process variables and their impact on vessel mass savings, material cost savings, processing time, manufacturing energy consumption, labor and structural benefits.
- Studying polymer material degradation under high-pressure hydrogen environment.

Technical Barriers

The project addresses the following technical barriers from the Manufacturing R&D section (3.5) of the Fuel Cell

Introduction

The goal of this project is to develop an innovative manufacturing process for Type IV high-pressure hydrogen storage vessels, with the intent to significantly lower costs. Part of the development is to integrate the features of high precision AFP and commercial FW.

In this project period, a vessel was designed that passed the burst test successfully. Boeing's improvements included re-machining the foam mandrels to resolve the wrinkling issues due to poor fit-up between the end caps and the liner, refining the AFP processes, and developing a new AFP head to reduce downtime and increase productivity for processing of pressure vessels. Energy and cost targets were improved significantly in the cost model developed by PNNL after the success of Vessel 7. PNNL also characterized polymer materials in high-pressure hydrogen environments.

Approach

The hybrid vessel designs were based on finite element analysis results to optimize strain distribution and achieve uniform displacement in the domes of the vessel.

Results

Vessel Designs

Vessel 3: At the time of writing the 2010 annual report, Vessel 3 was in the process of being manufactured. It achieved a burst pressure of 21,658 psi, which is lower than the requirement of current CSA America Hydrogen Gas Vehicle (HGV) standard of 22,843 psi. However, it was an improvement over Vessel 2 by almost 3,000 psi. (See Table 1 for test result summary.) Since the burst pressure was 95% of the standard's minimum burst requirement, the plan was to lower the peak strain of design 3 by 7%.

Vessel 4: The peak strain location of Vessel 4 was relocated to the cylinder section by adding localized hoops at the transitions between AFP and FW. The outer layers of FW composite were reordered to have a hoop as the outer layer (vs. helical). This was done to keep tension in the last helical circuit and reduce voids. Vessel 4 reached a burst pressure of 21,719 psi, below the design requirements (Table 1) and slightly lower than the burst value for Vessel 3, even though strains were reduced by 7% as planned. In post test analysis a 1" X 2" block was cut from the aft end and inspected under a microscope. The inspection showed that the second group of AFP layers had waviness on top of the FW surface, but the first AFP did not show any sign of waviness. It was concluded that the waviness of the second AFP layer was due to the non-uniform surface of the FW base layers that they were built on. When a layer of fiber is wavy, it does not carry the portion of the load that those layers are designed for.

Vessel 5: Vessel 5 was essentially completely redesigned while keeping certain key design characteristics of Vessel 1 (passed burst test) and applying the lessons learned from previous vessels: 1) use single AFP to avoid fiber waviness and streamline manufacturing process, 2) maintain or reduce strain values of Vessel 1, and 3) manufacture AFP end caps on rigid foam tool. The design was much improved from that of Vessel 1 in terms of fiber usage, stress distribution, and strain values. It achieved a burst pressure of 20,500 psi, which was lower than Vessel 4 but had a fiber reduction of 10.6 kg from Vessel 4 (Table 1).

Earlier installation of the AFP end caps (Figure 1) on Vessels 3 and 4 revealed that they did not adequately fit the contour of the liner. The caps required significant manipulation to align them onto the dome, ultimately resulting in wrinkled tows and lower strength. Therefore, the foam mandrels were re-machined to a new and more accurate surface according to the liner contour data defined and measured by a laser tracking system. The newly cut surfaces also included higher-fidelity features for the boss

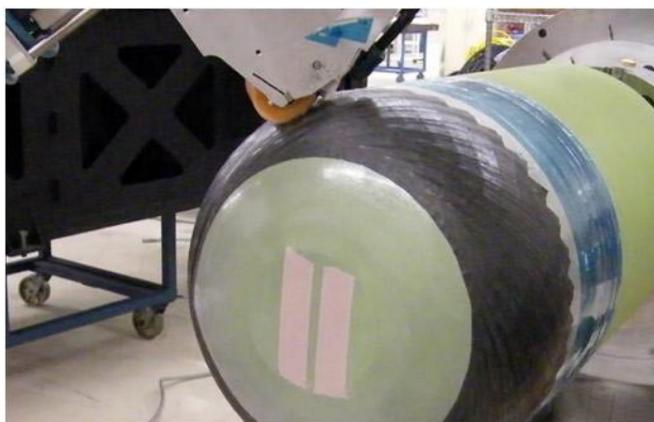

FIGURE 1. Fiber Placement of the End Cap (Older Generation Head)

TABLE 1. Vessel Test Result Summary

Vessel #	Weight (kg)	% Wt. Down from Baseline	Burst Pressure (psi)	% Under Std. ¹	Burst Area
0 (Baseline)	76.0	-	-	-	-
1	64.9	14.61	23,771	-	Mid Cylinder
2	N/A	-	18,666	18.29	Aft
3	67.11	11.70	21,658	5.19	Aft
4	65.04	14.42	21,719	4.92	Aft
5	54.44	29.37	20,500	10.26	Aft

7	58.63	22.86	22,925	-	Mid Cylinder
8	57.29 ²	24.62	- ³	-	-

¹ Current HGV standard burst pressure requirement is 22,843 psi.

² Continuous winding and additional squeegeeing contribute to even lower weight.

³ Cycle test ended after 13,500 cycles, thus no burst test afterward.

detail; further reducing wrinkling in the key polar regions. The better fit of the AFP end caps to the liner successfully eliminated wrinkling at each end of Vessel 5.

Vessel 6: Due to the inconsistencies seen in burst performance vs. fiber strains, Vessel 6 was built identically to Vessel 5 for destructive analyses. Half of the forward and aft ends of the vessel were sent to Boeing. At Boeing, computed tomography-scanning and photo-microscopy were performed to quantify porosity and resin rich areas within the structure, along with FW fiber waviness. At Quantum, after polishing the remaining ends, excessive voids were found in the aft end due to bridging (Figure 2). Bridging was caused by incorrect assumption of the "necking factor" value used in the design input file. Necking factor is defined as the ratio of fiber bandwidth at the polar opening vs. bandwidth in the cylinder section.

FIGURE 2. Voids are Shown in the Sectioned Aft Dome of Vessel 6

FIGURE 3. Vessel 7 Burst Test Result Showing Rupture in Mid Cylinder

Vessel 7: It was believed that the bridging issue was causing separation and reduction of load translation between the FW layers, which led to Vessel 5 failure. After entering the new necking factor, the models on both fwd and aft ends showed multiple opportunities to reduce bridging in the design. The excessive bridging locations were resolved by adjusting the fiber angles and polar openings. The total weight savings on Vessel 7 was 17.37 kg or 22.9% from the baseline (all FW) vessel (Table 1). Vessel 7 passed the burst test at 22,925 psi. The burst location was in the mid cylinder as designed (Figure 3).

Vessel 8: Vessel 8 was built identically to Vessel 7 for cycle test, but it developed a leak after 13,500 cycles, 1,500 cycles short of the requirement. Root cause of the leak will be determined in Phase III.

New Six-Tow Quarter Inch AFP Head Development

Boeing has built a prototype tow-placed head designed specifically for processing of pressure vessels. The ¼-inch, 6-tow machine has improved infrared heating capabilities and a more compact size enabled by the use of stainless

steel (vs. aluminum). Boeing's new head is able to apply fiber ½-inch closer to the polar boss. This enables a more-efficient, lower-weight pressure vessel design. Boeing has incorporated the ability to cut each individual tow, as well as a reverse-style cutter, allowing for higher speed cutting on the fly. Overall, Boeing has decreased downtime and increased productivity by improving the ease of operation and maintenance. The entire head opens up with only one tool allowing the operator to quickly clear jams. This increases the production of pressure vessels and reduces touch labor.

The head has been integrated onto a robotic cell, which will utilize a rail and a KUKA KR240 long arm system to provide more control and flexibility during lay-up. The system will allow the optimal placement of the robot base to minimize wasted motion and be capable of fiber placing a vessel with one tooling setup. An important characteristics of this cell is the significantly lower cost of the overall system compared to what is available in the industry.

Cost Model

Meeting the burst requirement with Vessel 7 showed that the AFP end caps can be successfully made in a parallel manufacturing line. This allows optimization of machine usage. Parallel AFP and FW processing lines reduce the vessel manufacturing time from 8.2 hr to 4.3 hr. This reduces the required number of FW cells by 48% and the number of AFP cells by 52% (for 500,000 units/year). This equals a \$30 per vessel savings in manufacturing cost. The reduced composite weight of Vessel 7 increased the specific energy from 1.5 to 1.78 kWhr/kgH₂ and reduced the vessel cost from \$23.45 to \$20.80/kW-hr.

Polymer Materials Characterization

PNNL has quantified the impact of high-pressure hydrogen environments on the mechanical properties of high density poly-ethylene (HDPE). Over 100 tensile specimens (ASTM D638 type 3) were tested after exposure to 4,000 psi H₂ to quantify the impact of H₂ concentration on the mechanical properties of polymers. Samples were soaked in the high pressure H₂ for at least 7 days per batch to ensure full H₂ saturation based on simple diffusion limited rate calculations.

Preliminary analysis of the standard HDPE H₂ exposed data shows reproducible trends. First, there is a nearly 20% decrease in elastic modulus that recovers as hydrogen diffuses from the material with time. Second, a nearly 10% decrease is seen in the tensile strength with a corresponding increase in ultimate strain (these are the peak values before the material necks), these also recover with time and escape of hydrogen from the HDPE. Recovery time scales were measured to be on the order of 1 day. Tests were also performed on a lower crystallinity material – low density poly-ethylene (LDPE). LDPE exposed to the same high pressure H₂ conditions demonstrates markedly different

behavior, with strong evidence of internal blistering and non-recoverable changes to the material. It appears that higher crystallinity and cross-linking densities are beneficial for reduced permeation and material durability under H₂ exposure.

Assessment of Alternate Composite Resins

Nonlinear stress analysis of the vessel composite layup was performed to estimate the increase in burst pressure that may be achieved by transitioning to a particle-reinforced resin with higher strength and stiffness. The ABAQUS finite element code was enhanced to include the Eshelby-Mori-Tanaka Approach for NonLinear Analysis model, which is a nonlinear composites material model that incorporates progressive damage and lamina failure criteria. The model with the standard epoxy closely predicted the actual burst pressure from testing, and the model with high performance filled epoxy predicted a 12% increase in burst pressure with the same composite lay-up.

Conclusions and Future Directions

- The hybrid manufacturing method is able to produce pressure vessels that achieve the required burst pressure and save carbon fiber (22.9% in Vessel 7) at the same time.
- Equipment and factory costs for hybrid process are small relative to fiber cost reduction.
- Absorption of H₂ by HDPE reduces the material's modulus and yield strength, but is reversible.
- Design vessel with lower-cost and lower-strength fiber to replace T700S for vessel outer layers.
- Perform testing on latest vessel design according to the latest automotive standards.
- Shake down improved AFP head design hardware for production.
- Update cost model.

Los Alamos National Laboratory, Los Alamos, NM

Project Start Date: October 1, 2007 Revised
Interagency Agreement (October 1, 2009)
Project End Date: October 1, 2009 Revised
Interagency Agreement (October 1, 2011)

Fiscal Year (FY) 2011 Objectives

- Identify and evaluate the capability and uncertainty of commercially available non-contact, high-speed scanning technologies for applicability to bipolar plate manufacturing process control.
- Using capabilities identified in the first objective, demonstrate smart assembly concept (new under revised interagency agreement).

Technical Barriers

This project addresses the following technical barriers from the Manufacturing R&D section of the Fuel Cell Technologies Program Multi-Year Research, Development and Demonstration Plan:

- (B) Lack of High-Speed Bipolar Plate Manufacturing Processes
- (F) Low Levels of Quality Control and Inflexible Processes

Contribution to Achievement of DOE Manufacturing R&D Milestones

This project will contribute to achievement of the following DOE milestones from the Manufacturing R&D

section of the Fuel Cell Technologies Program Multi-Year Research, Development and Demonstration Plan:

- **Milestone 7:** Develop manufacturing [quality control measurement] processes for graphite resin, natural flake graphite, and metal plates. (4Q, 2010)
- **Milestone 12:** Demonstrate pilot scale processes for assembling stacks. (4Q, 2013)
- **Milestone 13:** Complete development of standards for metrology of PEM fuel cells. (4Q, 2010)

FY 2011 Accomplishments

- Completed the design, fabrication and testing of a dedicated fuel cell metrology station using Aerotech translation stages (stages procured in August 2010) and Keyence laser spot triangulation probes.
- There are several interesting features to note in this design:
 - We integrated two laser spot triangulation probes that are titled in opposing directions. The use of two tilted probes allows collection of data from the side walls of the channels; a single probe looking straight down cannot acquire any side wall information.
 - The data from the laser triangulation probes is synchronized with the position from the translation stage and therefore velocity fluctuations are no longer a concern.
 - The stage has a maximum travel speed of 2,000 mm/sec. We have evaluated channel depth and height on fuel cell plates from speeds of 30 mm/sec to 500 mm/sec without noticing any significant degradation in accuracies at higher speeds.
- Performed numerous tests on the fuel cell station using calibrated gage blocks. The details are recorded in our project update submitted on January 21st, 2011 [1] and in a paper currently under review.
- Measured channel width and height on carbon bipolar plates using this non-contact system. Width and height results were within $\pm 2 \mu\text{m}$ of the values obtained using a contact coordinate measuring machine (CMM).
- Performed detailed uncertainty budgets for channel width and height for carbon bipolar plates which showed expanded uncertainty of $6 \mu\text{m}$ ($k=2$) for width and $3.8 \mu\text{m}$ ($k=2$) for height. The details are recorded in [2].
- Completed design of fixtures required to perform thickness measurements on fuel cell plates (one probe looking down on the plate while the second probe is positioned below the plate looking up). Thickness

and parallelism measurements on plates are critical for ‘smart assembly’.

Introduction

The objective of this project is to enable cost reduction in the manufacture of fuel cell plates by providing a rapid non-contact measurement system that can be used for in-line process control. Manufacturers currently either visually inspect plates or use machine vision systems for verifying tolerances. Such methods do not provide the sub-10 μm accuracy that manufacturers are targeting. In this context, we have studied available non-contact sensors in the market for their suitability to be used for fuel cell plate metrology. From our studies, we have short listed laser spot triangulation probes as one of the promising candidates for further exploration. We have since incorporated these probes in a unique two-probe system to develop a rapid yet high accuracy non-contact system that manufacturers can adopt towards process control and metrology. We plan on further extending our design to perform thickness measurements using opposed probe configuration that will enable ‘smart assembly’. The concept of “smart assembly” is that if plate parallelism is measured and tagged to each plate, then assembly can be done in an automated fashion where plates are configured ideally to minimize the overall stack parallelism. This will allow lower tolerances on individual plate parallelism.

Approach

We studied numerous sensors to assess their suitability as a rapid non-contact dimensional measurement tool for bipolar fuel cell plates. We selected laser spot triangulation probes for further investigation because they offered large range (± 5 mm) and micrometer level resolution. Our approach then is to build a dedicated fuel cell metrology station with Aerotech translation stages and laser triangulation probes as the non-contact probe of choice. We then intend to test the performance of our system using calibrated gage blocks and subsequently measure numerous bipolar fuel cell plates that have also been previously measured with a contact CMM. Such measurements will enable us to place bounds on errors; a detailed uncertainty budget will also be created to understand dominant error sources. Finally, we also plan on performing thickness and parallelism measurements using two laser triangulation probes (one probe looking down on the plate while the second probe is positioned below the plate looking up). Tagging each plate with thickness and parallelism data will enable the selection of those plates that reduce the combined total parallelism of the stack, a process we describe as ‘smart assembly’.

Results

During the last year, we have made significant progress in developing and testing our non-contact fuel cell metrology station. We describe major results next.

Characterizing Triangulation Probe Errors

Our investigations on laser triangulation probes revealed numerous error sources that impact dimensional measurements. Many of these error sources have been described in the literature before [3]; our studies have attempted to place bounds on errors for linear dimensional measurements and also serve to caution users that laser triangulation probes are not plug-and-play devices as they are often described to be in manufacturer’s literature. Despite their limitations, we believe these probes are superior to other non-contact options available currently, if carefully employed.

Our experiments studied the following factors: repeatability and noise levels, linearity errors, influence of material/optical properties on height and width measurements, effect of spot size on width measurements, side wall reflections, secondary reflections, and measurements at grazing angle. Figure 1 shows the linearity error over the 10 mm range of the probe for a ceramic and graphite test object. The manufacturer’s specification of ± 5 μm is only valid for the ceramic case; it is clear from Figure 1 that it does not hold for the graphite case. While these and other such results are summarized in [1] and also in a paper currently under review, we highlight one particular source of error that has significant implications for fuel cell plate measurements under our dual-probe design (discussed next), namely, the influence of part material and optical properties on dimensional measurements. It is well known that triangulation probe suffers from volumetric scattering and surface penetration. We have used ceramic gage blocks and demonstrated experimentally that width and height errors of the order of 10 μm are possible when material/optical properties are not identical for the different

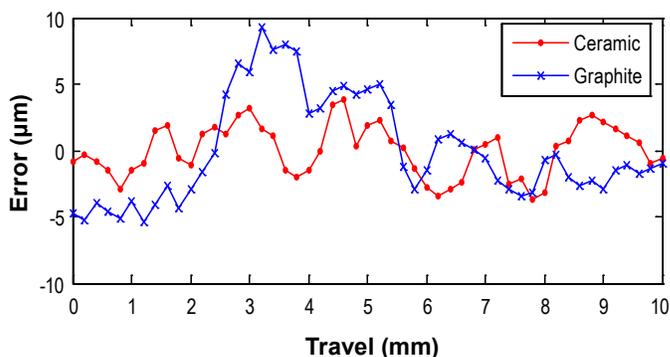

FIGURE 1. Linearity Error when the Probe’s Laser is Incident at 25° with the Surface

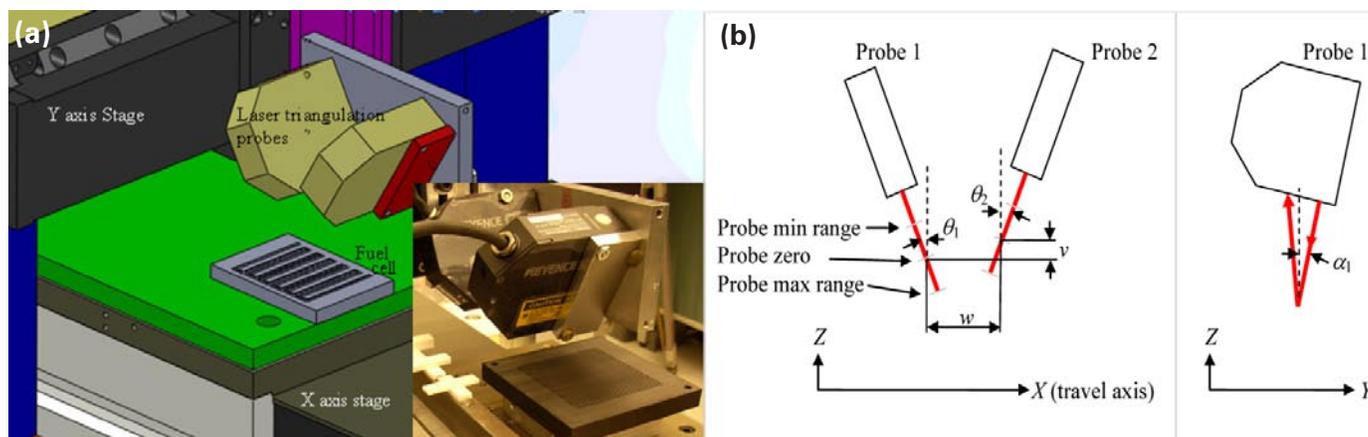

FIGURE 2. (a) The fuel cell metrology station showing two laser triangulation probes, each tilted in opposing directions to obtain side wall information. (b) Six system parameters to be determined by calibration.

surfaces that comprise a height or width feature, although these surfaces may appear to be visually similar. This implies that care must be taken in calibrating the dual-probe system with an artifact made of identical material as the part.

The Dual-Probe Fuel Cell Metrology Station

One unique aspect of our fuel cell station design is that we have incorporated two laser triangulation probes that are tilted in opposing directions as Figure 2(a) shows. The purpose of having two tilted probes is to be able to acquire channel side wall information, which a single probe looking straight down cannot accomplish. But having two probes necessitates the determination of six system parameters (tilt angles and offsets) shown in Figure 2(b); we have developed a calibration procedure for this purpose and have described it in detail in [2]. Determining these system parameters accurately is essential in superimposing the data from the two probes into a common frame of reference.

While it may appear that the tilt angle θ of the probes can be determined by measuring a calibrated height block, we show in [2] that such measurements are corrupted by misalignment angle α and are therefore not very accurate. We further demonstrate that vertical profile measurements (measurements on the vertical face of a gage block) can yield much higher accuracies because the misalignment angle α can be separated out. The mathematics and uncertainty in such calculations are described in [2].

Bipolar Plate Measurements and Uncertainty

We have compared measurement results on fuel cell plates from our non-contact system against a contact CMM. Our results for channel height and width on a graphite bipolar plate agree to within $\pm 2 \mu\text{m}$ as Figure 3 shows. The expanded uncertainties on height and width for the contact CMM are $0.5 \mu\text{m}$ and $1.7 \mu\text{m}$. We have developed detailed

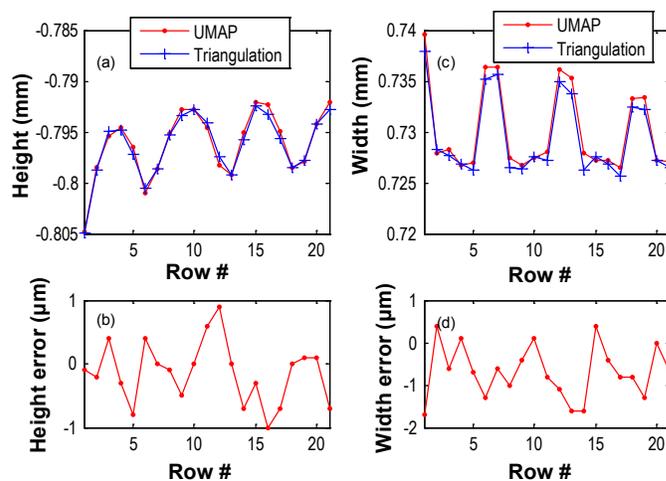

FIGURE 3. (a) Measured height of each row using both the ultrasonic micro and accurate probe (UMAP) and the dual-probe laser triangulation system (b) Height error for each row (c) Measured width of each row using both the UMAP and the dual-probe laser triangulation system (b) Width error for each row.

uncertainty budgets for the graphite bipolar plate channel height and width measurements; they are described in [2]. We estimate expanded uncertainty of $6 \mu\text{m}$ ($k=2$) for width and $3.8 \mu\text{m}$ ($k=2$) for height using our non-contact system on the graphite part. Major contributors to the uncertainty are the probe linearity errors and pitch motion of the stage.

Speed Tests

We performed width measurements at different speeds on an etched plate. The results from 30 mm/sec to 500 mm/sec are shown in Figure 4. There is no significant degradation in accuracy at 500 mm/sec in comparison to that at 30 mm/sec as Figure 4 shows. We have also verified the same for height measurements; those data are not shown here.

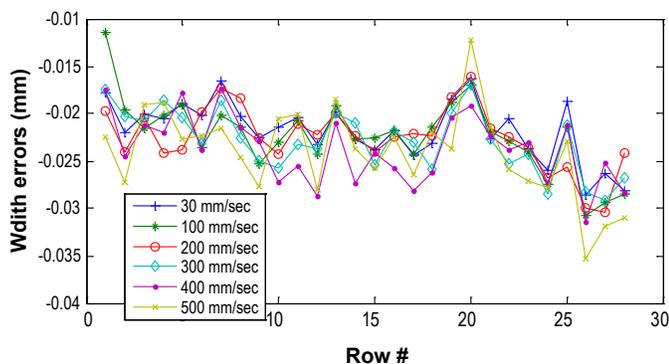

FIGURE 4. Width Errors at Different Speeds as a Function of Row # for an Etched Plate

Conclusions

To date, we have designed, built, and tested a dedicated dual-probe fuel cell station system for dimensional inspection of fuel cell plates. The two probes are oriented in a novel configuration that increases the accuracy of lateral dimensions and simultaneously provides the ability to capture side wall information for form evaluation. With this design we performed numerous experiments to study the different error sources (such as edge effects, linearity errors, spot sizes, etc.) in laser triangulation probes and their impact on dimensional measurements. With a thorough understanding of the error sources the limitations of these probes can be overcome making their application suitable for fuel cell metrology. Following careful evaluation of the sensor errors and approaches to minimizing them we made comparison measurements of channel height and width using sample fuel cell plates fabricated by common methods that were previously measured using a micro-feature CMM. With a high quality fuel cell flow field plate we demonstrated agreement with reference measurements to within $\pm 2 \mu\text{m}$. From our error source investigation and intercomparison measurements we developed a detailed uncertainty for both height and width measurements. We then furthered our capability study to evaluate accuracy as a function of scan speed, finding that there was no noticeable degradation of accuracy up to 500 mm/s.

Future Directions

The final phase of this project involves developing a configuration that provides the capability to measure variation in plate thickness. The opposing probe design modification has been developed and the additional mounting fixtures are being fabricated. Upon completion of the new probe fixturing components we will begin demonstrating the capability of the system to measure variation in thickness along the development of a detailed measurement uncertainty. From these data we intend to show that parallelism from variation-in-thickness can be derived and used for the concept of “smart assembly.”

Project End Date: October 1, 2009 Revised
Interagency Agreement (October 1, 2011)

- **Milestone 2.** Develop continuous in-line measurement for MEA fabrication. (4Q, 2012)
- **Milestone 13.** Complete development of standards for metrology of PEM fuel cells. (4Q, 2010)

FY 2011 Accomplishments

- Demonstrated 0.03 to 0.05 mg/cm² sensitivity to loading differences using 3M pure Pt catalyst nano-structured thin-film (NSTF) samples that included four different loadings ranging from 0.05 mg/cm² to 0.20 mg/cm² (September 2010).
- Investigated transmission properties of the thin NSTF samples and eliminated interference from the substrate (sample holder) material reflection (October 2010).
- Using sample reversal along with atomic force microscopy (AFM), we discovered that the cause of a repeatable asymmetrical reflectivity response for the 0.20 mg/cm² pure Pt NSTF CCM was due to a large physical macroscopic sample asymmetry (November 2010).
- Demonstrated 0.03 to 0.04 mg/cm² sensitivity to loading differences using W.L. Gore & Associates Pt on carbon catalyst-coated membrane (CCM) (A510/M710.18/C510) samples that included four different loadings ranging from 0.10 mg/cm² to 0.40 mg/cm² (December 2010).
- Procured and took delivery of a spectroscopic ellipsometer which enables measurements of material optical properties n and k that are critical to the modeling effort (February 2011).
- Using the new ellipsometer, began spectroscopic measurements of constituent materials supplied by 3M that comprise their NSTF CCM and attempted bulk material measurements (using effective medium approximation) of the current Gore samples (March 2011).
- Continued refinement of our simulation models for both the 3M NSTF and the W.L. Gore & Associates Pt on carbon CCM (optical constants remain only limitation to having a useful working model) (March 2011).

Fiscal Year (FY) 2011 Objective

Evaluate the suitability of optical scatterfield metrology (OSM) as a viable measurement tool for in situ manufacturing process control of dual-side simultaneous catalyst coating of membranes.

Technical Barriers

This project addresses the following technical barriers from the Manufacturing R&D section of the Fuel Cell Technologies Program Multi-Year Research, Development and Demonstration Plan:

(F) Low Levels of Quality Control and Inflexible Processes

Contribution to Achievement of DOE Manufacturing Milestones

This project will contribute to achievement of the following DOE milestones from the Manufacturing R&D section of the Fuel Cell Technologies Program Multi-Year Research, Development and Demonstration Plan:

- **Milestone 1.** Develop prototype sensors for quality control of MEA manufacturing. (4Q, 2011)

Introduction

Industry has identified the need for high-speed, in situ process control measurement techniques for controlling the quantity of the platinum in the catalyst layer and for the rapid identification of critical defects. Online

X-ray fluorescence (XRF) is the current in situ technique for controlling the various parameters of interest, most commonly catalyst loading; however this technique provides the total through sample platinum loading thus must be implemented prior to the transfer of the anode and cathode catalyst layer to the membrane in the production of a CCM. The ideal solution would provide in-line process control of the finished product (CCM) by way of dual-side simultaneous but independent measurement of catalyst loading. The solution would eliminate concerns related to platinum lost and not accounted for during the decal transfer step and it would ultimately enable real-time loading process control when dual-side direct catalyst layer application becomes the standard approach.

The Mechanical Metrology Division within the Physical Measurement Laboratory has years of expertise with a technology identified as OSM [1], specifically its development as a process control tool for the semiconductor industry. This technique is a combination of the best attributes of traditional bright-field optical microscopy and scatterometry. This technique focuses on the complex optical signatures of subwavelength size features, where the response can be optimized by varying the illumination angle, varying the illumination source wavelength, and application of various image analysis algorithms. The overall objective of this project is to demonstrate the applicability of the OSM technique to this application with the hope that it will provide proton exchange membrane (PEM) CCM manufacturers with an automated high-throughput approach for process control in inspection of Pt loading with sensitivity equal to or better than that currently provided by XRF and simultaneous identification/quantification of other parameters of interest, such as critical defects. Model-based simulations will be developed concurrently as they are critical to the study and optimization of this technique for this application and will ultimately give manufacturers insight that will enable them to tune their measurement equipment to the parameter(s) of interest as design changes are made.

Approach

The initial focus, driven by industry input, is to demonstrate that the OSM tool is sensitive to differences in catalyst loading. To reach this Go/No-Go point this project has relied heavily on support from CCM manufacturers, specifically in the supply of samples by which sensitivity studies could be performed. CCM manufacturers were also helpful in establishing a benchmark catalyst loading sensitivity of 0.01 mg/cm^2 which is equivalent to that of the online XRF tool currently used. At this juncture, we now know that the tool is indeed sensitive to changes in catalyst loading at the benchmark level based on a sample set of 3M Pt alloy NSTF-type CCMs. With sensitivity successfully demonstrated, the remainder of the project is dedicated to developing accurate analytical models for each type of CCM tested then to use these models for

simulations aimed at understanding and optimizing the tool's sensitivity to catalyst loading based on variation of the adjustable parameters of the tool and to further extend the study of the applicability of the tool to other critical catalyst layer parameters identified by the manufacturers. In the development of these models, we will again rely heavily on CCM manufacturers to supply specialized samples so that we can experimentally obtain optical constants for the constituent materials which are critical to ensuring accuracy. Lastly, to claim that a thorough investigation has been performed we aim to demonstrate the tool's capabilities on many of the common types of CCMs being manufactured, these include 3M's NSTF CCM with Pt and Pt alloy catalysts and the different conventional Pt on carbon-based CCMs made by several manufacturers.

Results

At the beginning of 2011, we determined that the Pt loading sensitivity was 0.03 to 0.05 mg/cm^2 for the 3M NSTF pure Pt CCM samples with loadings of 0.05 , 0.10 , 0.15 , and 0.20 mg/cm^2 (Figure 1).

However, the reflectivity signature versus illumination angle for the 0.20 mg/cm^2 , not shown in Figure 1, appeared non-symmetrical in comparison to the other three samples. Additionally, these pure Pt samples did not appear as opaque as the pure Pt alloy samples did thus we became concerned about transmission of the light through the sample and the effect of the reflection from the substrate or sample holder material. Both findings could be contributing to the

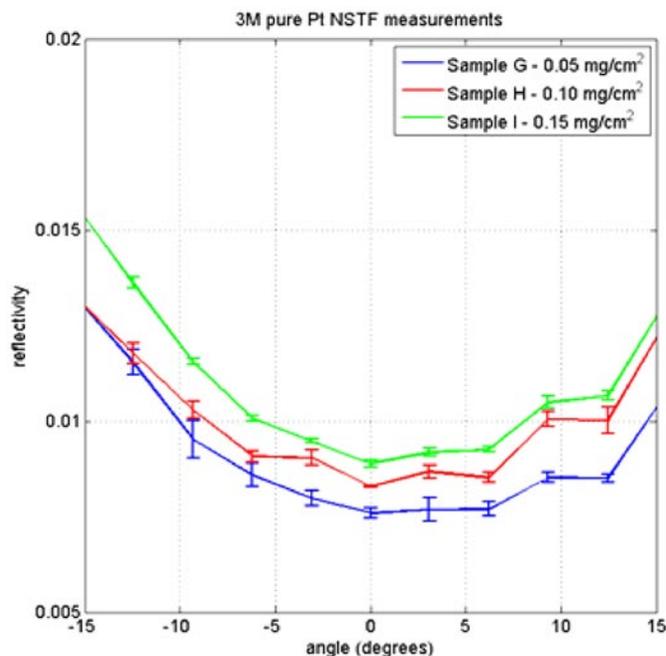

FIGURE 1. 3M NSTF pure Pt sample loading data. The separation between the curves relative to the error bars is a measure of the sensitivity.

increased variability as indicated in the calculated sensitivity level, which is short of the 0.01 mg/cm^2 target.

In order to determine if the asymmetry was associated with the optical tool or the sample, we performed a physical reversal of the sample. From this data seen in Figure 2, the asymmetry for the suspicious sample rotated with the reorientation of the sample but similar measurements using one of the other three samples did not change thus this was

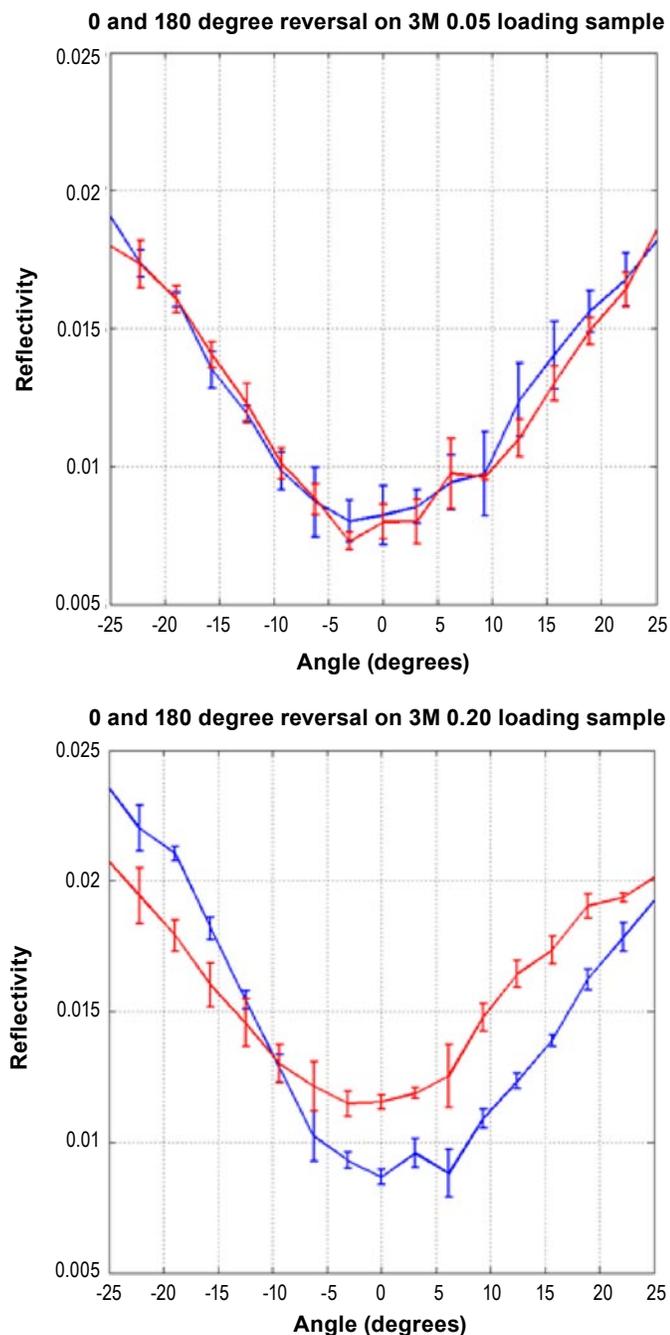

FIGURE 2. The plot on the top is the 0 and 180 degree reversal data for the 0.05 mg/cm^2 sample. The plot on the bottom is the 0 and 180 degree reversal data for the 0.20 mg/cm^2 sample, which displays the asymmetric behavior.

determined to be sample effect. To further understand the cause of the asymmetry our investigation focused on the sample. With the aid of an AFM we measured the profile of the samples macroscopic structure and compared the results from similar measurements performed on the other samples to find that there is a larger than normal asymmetry of the unique macrostructure geometry. The asymmetry is unimportant to the performance of the fuel cell, thus we were advised to find a way to make the measurement insensitive to this effect. This remains an ongoing effort. With regards to the transmission concern, experiments were performed where the intensity of the illumination source was significantly increased and where we changed the reflectivity characteristics of the substrate by introducing light absorbing material, both caused unexpected changes in the signature profile however the sensitivity and offsets between the samples remained. This too remains a work in progress and it is our hope that accurate simulation models will give us greater insight into these two effects.

With sensitivity demonstrated on both catalyst compositions using the 3M NSTF samples, we investigated the applicability of the tool to catalyst loading sensitivity using W.L. Gore & Associates conventional Pt on carbon CCM samples of 0.10, 0.20, 0.30, and 0.40 mg/cm^2 loadings (A510/M710.18/C510). We performed experiments varying the angle of illumination and wavelength on two different tools. For the angle resolved measurements, sensitivity was demonstrated on the order of 0.03 to 0.04 mg/cm^2 . Excellent static repeatability (multiple measurement scans same location) was shown for the wavelength resolved measurements. Performing wavelength resolved measurements at five locations on multiple days revealed variations in loading from one location to the next (on the scale of several millimeters apart), which makes the overall repeatability worse. However, this is not a limitation of the technique, it is a sample issue. This static repeatability and localized variation data are shown in Figure 3.

An integral part of the OSM technique is electromagnetic scattering simulation of the samples being measured. Simulation provides a flexible and efficient method to evaluate the various parameters that have an effect on the actual physical measurement. Accurate simulation requires accurate inputs to the models, such as target dimensions, layer thicknesses, surface roughness, materials optical properties (complex index of refraction), etc. NIST procured and took delivery of a spectroscopic ellipsometer which enables measurements of material optical properties (n and k) that are critical to the modeling effort (February 2011). Using this new ellipsometer, NIST began spectroscopic measurements of constituent materials supplied by 3M that make up their NSTF CCM and attempted bulk material measurements of the current Gore samples (March 2011) as shown in Figure 4. In performing these measurements, it became apparent that surface roughness was limiting our ability to measure the n and k of the materials and began using an effective medium approximation for evaluating the materials optical

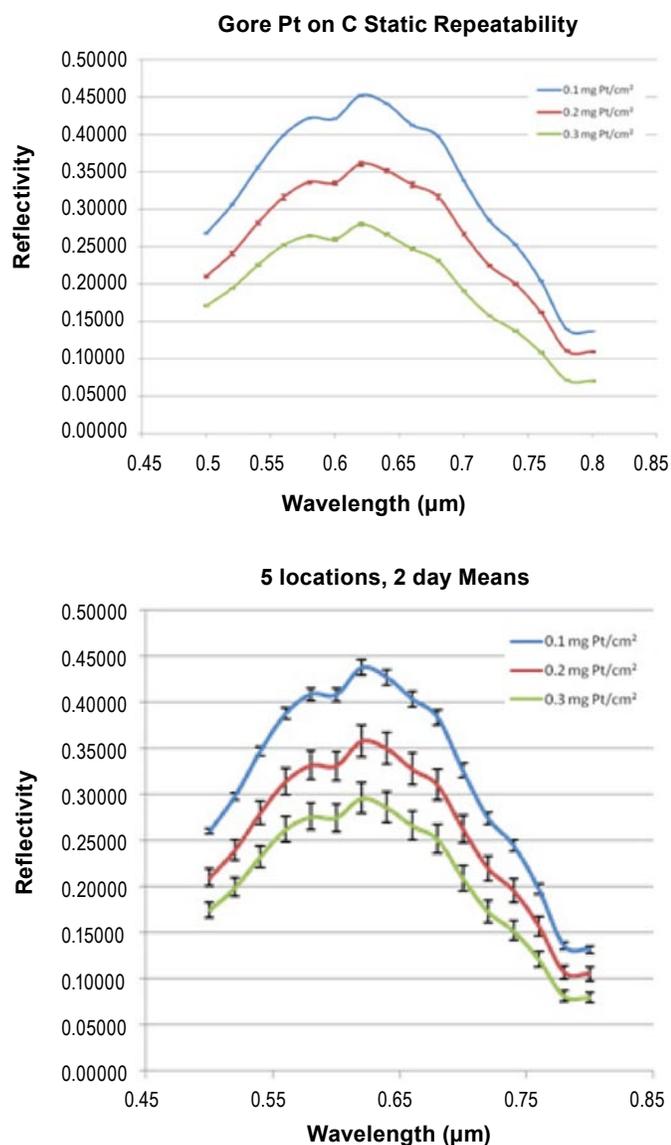

FIGURE 3. The plot on the top shows static repeatability data, looking at one location on each loading sample numerous times. The plot on the bottom is localized variation data, looking at five different locations on each loading sample over multiple days.

properties. We continued refinement of our simulation models for both the 3M NSTF and the W.L. Gore & Associates Pt on carbon (optical constants remain only limitation to having a useful working model) (March 2011).

Conclusions

The work presented for this project, to date, undeniably shows that OSM has sensitivity to catalyst loading regardless if the loading is pure Pt or a Pt alloy. The ability to achieve sensitivity levels equivalent to the 0.01 mg/cm² benchmark has been shown for the sample types investigated. From the conventional Pt on C catalyst CCM samples we clearly

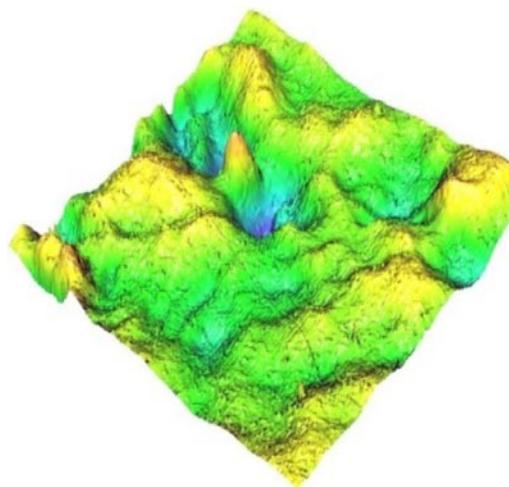

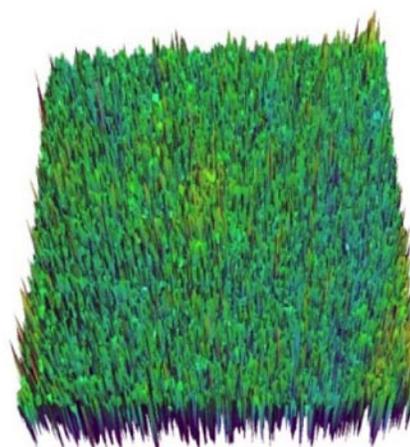

FIGURE 4. The plot on the top is a measure of the surface roughness of the Gore PEM layer. The plot on the bottom is a measure of the surface roughness of the 3M PEM layer.

see that this sensitivity level is achievable, however local variations in catalyst loading increase the uncertainty of assigning a definitive loading figure to a sample. Also from the work to date we see that this technique is clearly sensitive to other variables whether they are other sample specific parameters (i.e., macro geometry) or external (i.e., through sample transmission/background interference). These issues alone solidify the need for determination of material optical properties in support of the development of accurate models, which has eluded us to this point. Furthermore, optical property determination is not a simple task and in itself requires a significant effort. Support from major manufacturers has been excellent but sensitivity regarding intellectual property rights always impacts the rate of progress. At this juncture, we clearly have all the elements in place to make commendable strides towards true optimization of the OSM tool for this specific application. It is our belief that manufacturers like 3M and W.L. Gore & Associates see the potential for this measurement technique thus are eagerly

awaiting completion of the development work and subsequent availability of a commercialized product.

Future Directions

Our focus for the remainder of this project will be acquiring much needed material optical constants using our new spectroscopic ellipsometer and with these constants we intend to refine our models to a level that predictive simulations can be performed to study sensitivity to different variables ultimately leading us to an optimized tool configuration that may be unique to the samples of interest. An accurate model will be achieved when predictions can be made using the model and those predictions verified experimentally. Concurrently, we hope to explore the sensitivity of the technique to different defects identified by the manufacturers as being critical through the measurement of samples with known defects and investigated further through simulation efforts.

VII. TECHNOLOGY VALIDATION

VII.0 Technology Validation Sub-Program Overview

Introduction

The Technology Validation sub-program demonstrates, tests, and validates hydrogen and fuel cell technologies and uses the results to provide feedback to the Program's research and development activities. The Technology Validation sub-program has been focused on conducting learning demonstrations that emphasize co-development and integration of hydrogen infrastructure with hydrogen fuel cell-powered vehicles to permit industry to assess progress toward technology readiness. As the vehicle and infrastructure demonstrations are coming to a close, the sub-program is increasing its focus on other areas, such as combined hydrogen, heat, and power (tri-generation or CHHP) as well as stationary power applications.

Goal

Validate—under real-world operating conditions—the status, relative to Program targets, of hydrogen and fuel cell technologies that will be used in both the initial market entry and early market periods of fuel cells for transportation and stationary power generation.

Objectives¹

- **2014:** Validate a stationary fuel cell system that co-produces hydrogen and electricity at 40% efficiency, with 40,000-hour durability.
- **2019:** Validate fuel cell electric vehicles (FCEVs) achieving 5,000-hour durability (service life of vehicle) and a 300-mile driving range between fueling.

Fiscal Year (FY) 2011 Technology Status

National Learning Demonstration

In 2011, the National Learning Demonstration—a government-industry cost-shared project initiated in 2004 with four automobile and energy company teams—continued to provide data for evaluating the technology status with respect to fuel cell durability, driving range, and power park demonstrations. Six years of the seven-year project are complete. A total of 155 vehicles have been deployed through the first quarter of FY 2011, with 23 currently in operation. Thus far, more than 3 million miles have been traveled by the FCEVs in the project and 140,000 kg of hydrogen has been either produced or dispensed, with some of this hydrogen being used in vehicles outside the Learning Demonstration. New durability results will be available in autumn 2011; however, 2010 durability results indicate fuel cell durability exceeded 2,500 hours. Fuel cell vehicles have met or exceeded the 250-mile driving-range goal and fuel cell system efficiency data at 25% net power is 53–59%, which is close to the DOE target of 60%. Figure 1 shows all of the major key performance metrics that have been reported in the National Hydrogen Learning Demonstration.

- **General Motors (GM) Hydrogen Vehicle and Infrastructure Demonstration and Validation:** GM has deployed 60 vehicles, demonstrating two generations of GM's proprietary fuel cell technology. GM continues to operate and maintain 10 baseline Phase 2 FCEVs through 2011 or until failure. In 2010, GM inserted ten additional Phase 2 FCEVs equipped with technology developed during the initial part of Phase 2 to extend learnings (Figure 2). GM has also established retail and retail-like hydrogen stations for public fueling: Six fueling stations are in operation across the Eastern and Western regions, with various types of hydrogen generation and delivery—such as delivered compressed gas and on-site electrolysis. Two stations are infrared capable and able to fast fill more than three vehicles back-to-back. Hydrogen quality testing has been completed, and stations have been tested at 700 bar.
- **Mercedes-Benz North America:** Over the course of the project, the Mercedes Team has deployed 30 Gen-1 vehicles into customer hands for real-world operations in various climatic regions of the United States. The Mercedes Team has transitioned FCEV activities from research and development to mainstream

¹Note: Targets and milestones are under revision; therefore, individual progress reports may reference prior targets.

commercial activities, and they have now begun customer operations of production-level Gen-2 vehicles. (The first Gen-2 FCEVs were delivered to external customers in December of 2010.) B-Class F-CELL vehicles have been incorporated into Mercedes' standard business processes within departments such as Warranty, Customer Assistance, Parts & Distribution, as well as Roadside Assistance and Sales.

Learning Demonstration Key Performance Metrics Summary

Vehicle Performance Metrics	Gen 1 Vehicle	Gen 2 Vehicle	2009 Target
Fuel Cell Stack Durability			2,000 hours
Max Team Projected Hours to 10% Voltage Degradation	1,807 hours	2,521 hours	
Average Fuel Cell Durability Projection	821 hours	1,062 hours	
Max Hours of Operation by a Single FC Stack to Date	2,375 hours	1,261 hours	
Driving Range	103-190 miles	196-254 miles	250 miles
<i>Fuel Economy (Window Sticker)</i>	42 – 57 mi/kg	43 – 58 mi/kg	no target
<i>Fuel Cell Efficiency at ¼ Power</i>	51 - 58%	53 - <u>59%</u>	60%
<i>Fuel Cell Efficiency at Full Power</i>	30 - 54%	42 - <u>53%</u>	50%

Infrastructure Performance Metrics			2009 Target
H₂ Cost at Station (early market)*	On-site natural gas reformation \$7.70 - \$10.30	On-site Electrolysis \$10.00 - \$12.90	\$3/gge
<i>Average H₂ Fueling Rate</i>	0.77 kg/min		1.0 kg/min

*Outside of this project, DOE independent panels concluded at 500 replicate stations/year:
 Distributed natural gas reformation at 1500 kg/day: **\$2.75-\$3.50/kg** (2006)
 Distributed electrolysis at 1500kg/day: **\$4.90-\$5.70** (2009)

FIGURE 1. Summary of Key Performance Metrics for the Learning Demonstration

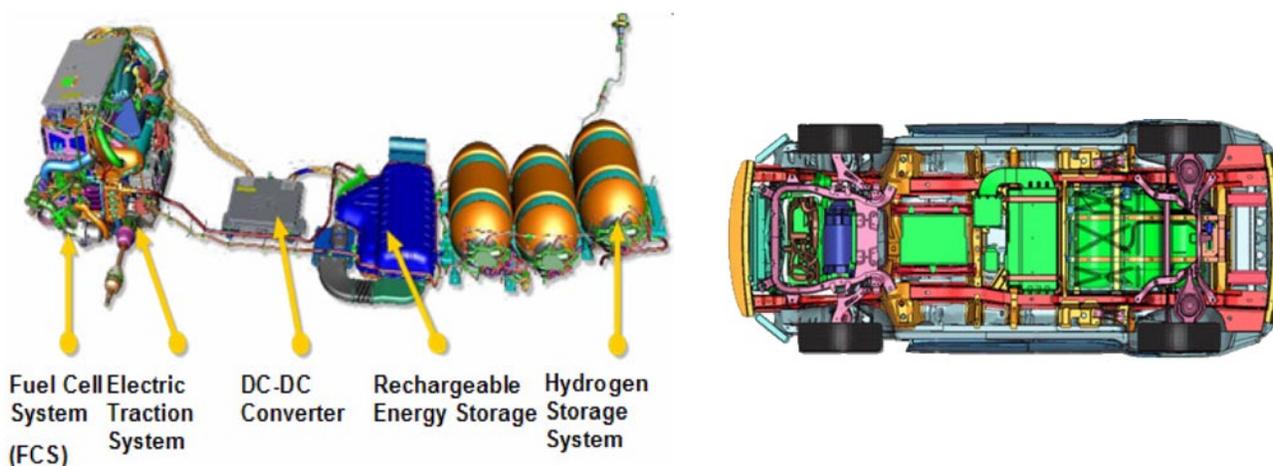

FIGURE 2. Gen-2 Chevrolet Fuel Cell Electric Vehicle with Technology Insertion

FY 2011 Accomplishments

National Learning Demonstration

The National Renewable Energy Laboratory (NREL) verified that Gen-2 learning demonstration vehicles maintained high fuel cell efficiency (53-59%). GM has concluded that FCEVs fully meet all functional needs for day-to-day customer use, FCEVs are fully functional in sub-freezing and cold weather conditions, and GM FCEVs exhibited very fast cold-start/drive-away times under sub-freezing temperatures. Mercedes-Benz demonstrated that A-Class F-CELLs exceed the 2,000-hour stack durability target. Initial test results show Gen-2 fuel cell stacks will most likely meet the 2015 DOE target of 5,000-hour durability. Engineers validated the 250-mile range and cold-start capability down to -17°C while reaching 50% of maximum power within 30 seconds (Figure 3). Hydrogen Infrastructure has been demonstrated to be customer-friendly in daily use by individual and fleet vehicle operators in a “retail-like” self-service mode.

FIGURE 3. Mercedes Engineers Validated Cold-Start Capability Down to -17°C while Reaching 50% of Maximum Power within 30 Seconds

Fuel Cell Bus Evaluation

By the end of April 2011, NREL had documented a total of 1.5 million miles of operation for three fuel cell bus (FCB) systems, with each operating in excess of 6,000 hours with no major repairs. One of these systems has logged more than 9,000 hours of service (Figure 4). Based on in-service fuel economies of 5 to 7 miles per kilogram of hydrogen, hybrid FCBs can achieve a range between 250 and 350 miles per fill, with no loss in cargo and passenger space (however, the added weight of the hydrogen storage system limits the number of standing passengers allowed on the bus). Fuel cell buses compared to baseline buses at three locations showed a fuel economy improvement ranging from 48% to 123% over diesel and compressed natural gas (CNG) baseline buses, respectively. Transit routes are unique for each location, so the duty cycles varied between the locations.

FIGURE 4. In FY 2011, NREL completed their first report on a next-generation fuel cell bus. The bus, which is in service at SunLine Transit Agency in Thousand Palms, California, is a New Flyer 40-foot bus with a Bluways hybrid system, Ballard fuel cells, and lithium-ion batteries. The bus has accumulated more than 9,000 miles and 818 hours on the fuel cell, with an average fuel economy of 5.75 miles per kg. This is nearly two times higher than the fuel economy for the baseline CNG buses.

California Hydrogen Infrastructure Project

In early 2011, construction was completed on the world’s first fueling station supplied by a hydrogen pipeline (Figure 5), which was partially funded through a prior year congressionally directed project. This project aims to demonstrate a low-cost, reliable supply of hydrogen. The station, which is located in Torrance, California, close to an existing Air Products hydrogen pipeline, was developed by Shell Hydrogen. A 4-kg/hr compressor skid has been installed, along with storage for 100 kg of hydrogen at 7,777 psig and

FIGURE 5. The Dispenser Area at Shell's Torrance, California, Fueling Station, which is Supplied by an Air Products Pipeline

FIGURE 6. HF-150 Mobile Refueler at the District Office of the U.S. Forest Service in Placerville, California

20 kg of hydrogen at 15,000 psig. This station dispenses hydrogen according to SAE International technical information report J2601, and it includes the first example of hydrogen purification technology for production of an ultra-pure hydrogen stream from an industrial-grade pipeline supply. Two dual dispensers for both 350- and 700-bar hydrogen have been installed, and four vehicles can be filled simultaneously. Based on a 50% compressor on-stream factor, the station will have the capacity to dispense 48 kg/day, enough to refuel approximately 12 cars per day. When starting with full storage, six cars can be filled in succession. Vehicle test fills were completed in March 2011.

In December 2010, Air Products completed a nine-month deployment of an HF-150 mobile refueler at the district office of the U.S. Forest Service in Placerville, California (Figure 6). The Air Products HF-150 maintains about 150 kg of gaseous hydrogen at 6,600 psig. It can dispense approximately 80 to 90 kg before needing to be refilled. It is ideal for small fleet fueling and offers the advantage of being an automated, highly reliable, cost-effective fueling system that can be easily installed.

Energy Station at Fountain Valley²

The Hydrogen Energy Station was installed at the Orange County Sanitation District (OCS D) in Fountain Valley, California, and became fully operational in FY 2011 as the world's first fuel cell energy station that produces electric power and hydrogen from wastewater treatment gas (Figure 7).

- The first co-production of hydrogen (using natural gas) at the Hydrogen Energy Station in OCS D took place in October 2010.
- Over 1,000 hours of operation in power and (power + hydrogen) modes has been completed during the performance period. The hydrogen produced has met all quality standards.
- The unit achieved nominal 54% efficiency (power + hydrogen) when operating in hydrogen co-production mode.
- In February 2011, the first hydrogen from the Hydrogen Energy Station at OCS D was sent to the hydrogen fueling station. Initial test fills of fuel cell vehicles at the hydrogen fueling station were completed in March 2011.
- In May 2011, operation on biogas from the wastewater treatment facility began.

²This station is based on a technology that co-produces power, heat, and hydrogen. This type of system is referred to as a CHHP (combined heat, power, and hydrogen or tri-generation) system. The station uses a high-temperature fuel cell to co-generate electricity, heat, and hydrogen. The fuel cell can use a diversity of hydrogen-rich fuels, including digester gas, natural gas, landfill gas, and syngas. This technology is expected to provide a source of cost-competitive hydrogen, which can be renewable when digester gas or landfill gas is used as the feedstock.

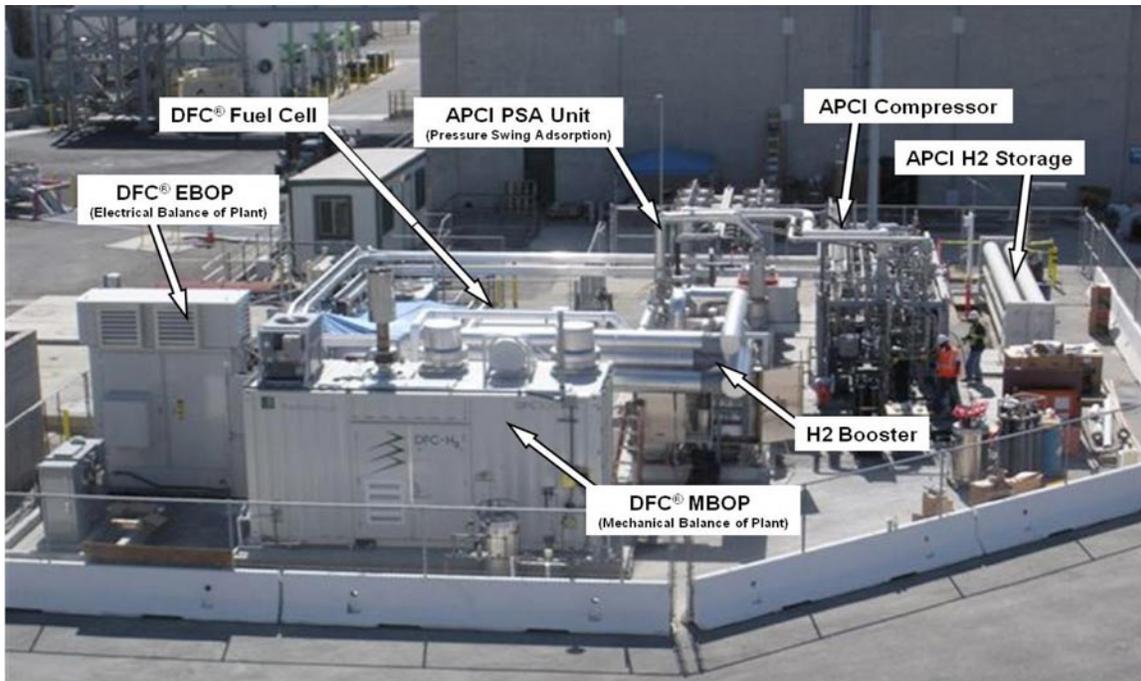

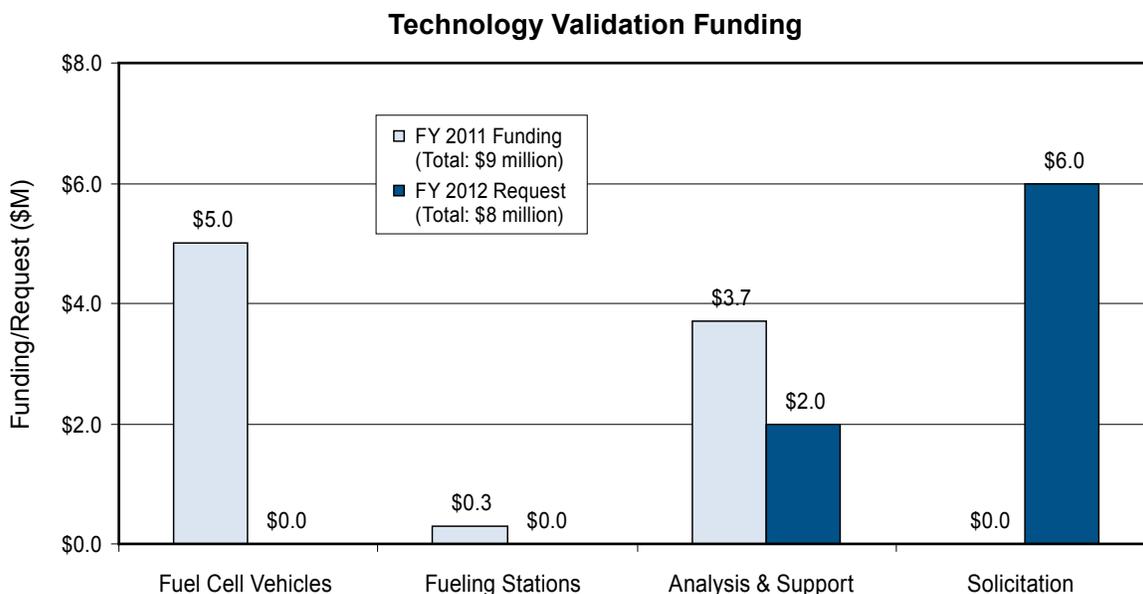

FIGURE 7. Energy Station at Fountain Valley, California (dispensing area not shown)

Budget

The funding portfolio for Technology Validation addresses the need to validate integrated hydrogen and fuel cell technologies for transportation and electric power generation in a systems context, under real-world operating conditions. In FY 2011, \$9 million in funding was appropriated for the Technology Validation sub-program. The President’s FY 2012 request includes \$8 million for Technology Validation activities.

FY 2012 Plans

A set of composite data products (CDPs) based on data collected through June 2011 (“Fall 2011 CDPs”) will be created for publication and reporting in November 2011. In the first quarter of FY 2012 the final two National Learning Demonstration projects (GM and Mercedes-Benz North America) will conclude and final reports will be prepared.

The Technology Validation sub-program will continue to collaborate with the Department of Transportation to validate fuel cell and hydrogen technologies in transit bus demonstrations conducted by the Federal Transit Administration. Efforts will also continue to harmonize data collection with other FCB demonstrations worldwide. Future FCB projects will include:

- Collecting, analyzing, and reporting on performance data for next-generation hydrogen-fueled vehicles in California, including AC Transit, SunLine, the City of Burbank, and additional sites as funding allows.
- Investigating the reliability and durability of FCBs as a part of ongoing evaluations; these efforts complement the DOE light-duty FCEV demonstrations
- Coordinating with Federal Transit Administration to ensure harmonized data-collection efforts for the National Fuel Cell Bus Program

The Integrated Hydrogen Energy Station will continue to be operated on anaerobic digester gas from the wastewater treatment facility. Data will be provided to DOE for the first six months of operation under a three-year program sponsored by the California Air Resources Board and the South Coast Air Quality Management District.

The Technology Validation sub-program is planning a funding opportunity announcement for FY 2012, subject to appropriations. Potential areas of interest may include: medium-scale (50- to 500-kW) CHHP production; medium-scale (50- to 500-kW) hydrogen and power production; on-site hydrogen generation for back-up power and specialty applications (e.g. material handling); fuel cell-powered ground support equipment for ports, terminals, and distribution hubs; and polymer electrolyte membrane fuel cells for stationary power. Final topics will consider input from the request for information that was issued to the stakeholder community and the public in FY 2011.

Phone: (202) 586-1723
E-mail: John.Garbak@hq.doe.gov

Start Date: October 2003

Projected End Date: Project continuation and
direction determined annually by DOE

Objectives

- By 2008, validate that hydrogen vehicles have a greater than 250-mile range without impacting passenger or cargo compartments.
- By 2009, validate 2,000-hour fuel cell durability in vehicles and hydrogen infrastructure that results in a hydrogen production cost of less than \$3.00/gallon gasoline equivalent (gge) (untaxed) delivered and safe and convenient fueling by drivers (with training).
- Help DOE demonstrate the use of fuel cell electric vehicles (FCEVs) and hydrogen infrastructure under real-world conditions, using multiple sites, varying climates, and a variety of hydrogen sources.
- Analyze detailed fuel cell and hydrogen data from vehicles and infrastructure to obtain maximum value for DOE and industry from this “learning demonstration.”
- Identify the current status of the technology and its evolution over the project duration.
- Provide feedback and recommendations to DOE to promote hydrogen and fuel cell research and development (R&D) activities and assess technical progress.
- Publish results for key stakeholder use and investment decisions by generating composite data products (CDPs) for public dissemination.

Technical Barriers

This project addresses the following technical barriers from the Technology Validation section (3.6.4) of the Fuel Cell Technologies Program Multi-Year Research, Development, and Demonstration Plan:

- (A) Lack of Fuel Cell Vehicle Performance and Durability Data
- (B) Hydrogen Storage
- (C) Lack of Hydrogen Refueling Infrastructure Performance and Availability Data
- (D) Maintenance and Training Facilities
- (E) Codes and Standards
- (H) Hydrogen from Renewable Resources
- (I) Hydrogen and Electricity Co-Production

Contribution to Achieving DOE Technology Validation Milestones

Throughout this project, researchers are gathering data and providing technical analysis that contributes to achieving the following DOE technology validation milestones from the Fuel Cell Technologies Program Multi-Year Research, Development, and Demonstration Plan:

- *Milestone 2: Demonstrate FCEVs that achieve 50% higher fuel economy than gasoline vehicles (Quarter [Q]3, Fiscal Year [FY] 2005).* This milestone was achieved.
- *Milestone 3: Decision for purchase of additional vehicles based on projected vehicle performance and durability and hydrogen cost criteria (Q4, FY 2006).* This milestone was achieved.
- *Milestone 4: Operate fuel cell vehicle fleets to determine if 1,000 hour fuel cell durability, using fuel cell degradation data, was achieved by industry (Q4, FY 2006).* This milestone was achieved.
- *Milestone 5: Validate vehicle refueling time of 5 minutes or less for a 5 kg tank [1kg/min] (Q4, FY 2006).* At the time of the milestone, we had analyzed more than 2,000 vehicle fueling events and had calculated an average rate of 0.69 kg/min and median rate of 0.72 kg/min, with 18% of the events exceeding the 1 kg/min target. Updates 3.5 years later, data from more than 25,000 fueling events showed improved results with an average rate of 0.77 kg/min with 23% of fueling events exceeding 1 kg/min. This milestone was achieved.
- *Milestone 7: Validate refueling time of 5 minutes or less for 5 kg of hydrogen (1 kg/min) at 5,000 psi through the use of advanced communication technology (Q4, FY 2007).* Currently, the data show that communication fills can fuel at a higher rate (up to 1.8 kg/min) and have an average fill rate 30% higher than non-communication fills (0.86 kg/min versus 0.66 kg/min). This milestone was achieved.
- *Milestone 8: Fuel cell vehicles demonstrate the ability to achieve a 250-mile range without impacting passenger cargo compartment (Q4, FY 2008).* This milestone

was achieved in 2008 using data from the Learning Demonstration results, with demonstrated range of 196–254 miles. In June 2009, an on-road driving range evaluation was performed in collaboration with Toyota and Savannah River National Laboratory. The results indicated a 431-mile on-road range was possible in southern California using Toyota's FCHV-adv fuel cell vehicle [1]. This milestone was achieved.

- *Milestone 10: Validate FCEVs 2,000-hour fuel cell durability using fuel cell degradation data (Q4, FY 2009).* On-road fuel cell voltage data from second-generation fuel cell systems were analyzed and published in the Fall 2009 CDP results. Results indicate that the highest projected team average to 10% voltage degradation for second-generation systems was 2,521 hours, with a four-team average of 1,020 hours. The Spring 2010 results only slightly increased the average (to 1,062 hours) and the highest team remained the same at 2,521 hours. This milestone was achieved.
- *Milestone 12: Validate cold start capability at -20 C (2Q, 2011).* This milestone was achieved and published in the Fall 2008 CDPs, demonstrating freeze starts from between -9 and -20 degrees C and documenting both time to drive away and time to maximum fuel cell power.
- *Milestone 23: Total of 10 stations constructed with advanced sensor systems and operating procedures (Q1, FY 2008).* This milestone was achieved.
- *Milestone 24: Validate a hydrogen cost of \$3.00/gge (based on volume production) (Q4, FY 2009).* Cost estimates from the Learning Demonstration energy company partners were used as input to an H2A analysis to project the hydrogen cost for 1,500 kg/day early market fueling stations. Results indicate that on-site natural gas reformation would lead to a range of \$8-\$10/kg and on-site electrolysis would lead to \$10-\$13/kg hydrogen cost. Although these results do not meet the \$3/gge cost target, two external independent panels concluded that distributed natural gas reformation could lead to \$2.75-\$3.50/kg [2] and distributed electrolysis could lead to \$4.90-\$5.70 [3]. This milestone was achieved outside the Learning Demonstration project.

Accomplishments

- Received and processed data quarterly from a total of 460,000 individual vehicle trips, amounting to more than 107 gigabyte (GB) of on-road data, since project inception.
- Created and published a total of 85 CDPs, with the Spring 2011 CDP results including five new CDPs since last year and updates to 18 previously published CDPs. The results emphasized the changes observed in the last 12 months, and included data from two Learning Demo manufacturers plus the Air Products' California Hydrogen Infrastructure Project.

- Documented and archived each quarter's analysis results in the Fleet Analysis Toolkit (FAT) graphical user interface. Executed NREL FAT to produce detailed data results and CDPs in parallel for convenient industry and internal review.
- Presented project results publicly at the Fuel Cell Seminar, EVS-25, the Fuel Cell and Hydrogen Energy Association conference, the Japanese Fuel Cell Demonstration Project conference, and the 2011 DOE Fuel Cell Technologies Program Merit Review meeting.
- Maintained NREL's Web page at http://www.nrel.gov/hydrogen/cdp_topic.html to allow direct public access to the latest CDPs organized by topic, date, and CDP number.
- Provided presentations of results to key stakeholders, including two FreedomCAR and Fuel technical teams (storage and fuel cells).
- Continued to leverage key NREL analysis tools and capabilities to enable results to be quickly generated from fuel cell forklifts and other early market fuel cell applications. This year we also began performing some new analyses on FCEVs that were developed originally for fuel cell forklifts.

Introduction

The primary goal of this project is to validate vehicle/infrastructure systems using hydrogen as a transportation fuel for light-duty vehicles. This means validating the use of FCEVs and hydrogen fueling infrastructure under real-world conditions using multiple sites, varying climates, and a variety of sources for hydrogen. Specific targets for 2009 were hydrogen vehicles with a range greater than 250 miles, 2,000-hour fuel cell durability, and \$3.00/gge hydrogen production cost (based on modeling for volume production). We are identifying the current status of the technology and tracking its evolution over the project duration, particularly between the first- and second-generation fuel cell vehicles, and further improvements to the second-generation vehicles demonstrated in the final two years. NREL's role in this project is to provide maximum value for DOE and industry from the data produced by this "learning demonstration." We seek to understand the progress toward the technical targets, and provide information to help move the Fuel Cell Technologies (FCT) R&D activities more quickly toward cost-effective, reliable hydrogen FCEVs and supporting hydrogen fueling infrastructure.

Approach

Our approach to accomplishing the project's objectives has been structured around a highly collaborative relationship with each industry team including Chevron/Hyundai-Kia, Daimler/BP, Ford/BP, General Motors/Shell,

and Air Products (through the DOE California Hydrogen Infrastructure Project). We are receiving raw technical data from the hydrogen vehicles and from the fueling infrastructure that enable us to perform unique and valuable analyses across all teams. Our primary objectives are to feed the current technical challenges and opportunities back into the DOE FCT R&D Program and assess the current status and progress toward targets.

To protect the commercial value of these data for each company, we established the Hydrogen Secure Data Center at NREL to house the data and perform our analysis. To ensure value is fed back to the hydrogen community, we publish CDPs twice a year at technical conferences to report on the progress of the technology and the project, focusing on the most significant results. Additional CDPs are being conceived as additional trends and results of interest are identified, and as we receive requests from DOE, industry, and the codes and standards community. We also provide our detailed analytical results (not public) to each individual company's data to maximize the industry benefit of NREL's analysis work and to obtain feedback on our methodologies.

Results

The results in FY 2011 came from analyzing an additional year of data (January–December 2010), creating five new and 18 updated CDPs, and presenting these results at several technical conferences. This brings the total number of CDPs published to 85. To accomplish this, we continued to improve and revise our in-house analysis tool, FAT. In 2007 NREL launched a Web page at http://www.nrel.gov/hydrogen/cdp_topic.html to provide stakeholders and the public with direct access to the results. Some results have also been presented publicly at conferences in the last year as two distinct sets of results (labeled “Fall 2010” and “Spring 2011”). All 85 of the results are now available on the Web site, so this report will include only a few highlights from the last year.

- **Status of Vehicle Deployment:** Figure 1 shows the cumulative number of vehicles that have been deployed by quarter and hydrogen storage system type since project inception. A total of 155 vehicles were deployed through December 2010; 132 are retired from the project and 23 are still on the road. Before the conclusion of the project about 40 vehicles should be on the road providing data to NREL with about 170 vehicles deployed since project inception.
- **Real-World Vehicle Driving Range:** In FY 2008, the driving range of the project's FCEVs was evaluated based on fuel economy from dynamometer testing and on-board hydrogen storage amounts and compared to the 250-mile target. Additional on-road data were obtained from second- and first-generation vehicles in 2009, as well as improved second-generation vehicles in 2010. This enabled us to evaluate the distribution of real-world driving ranges of all the

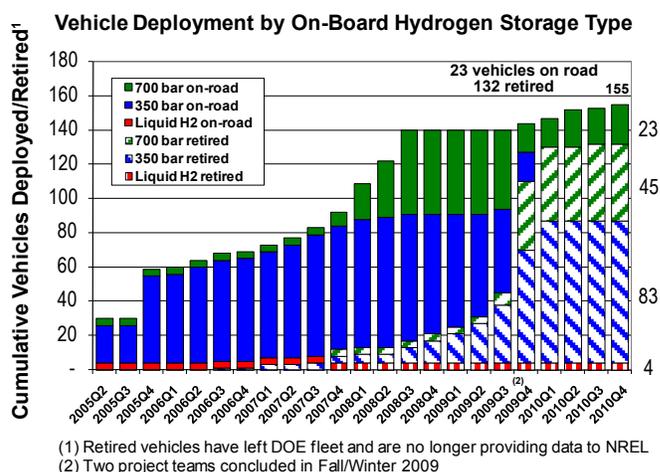

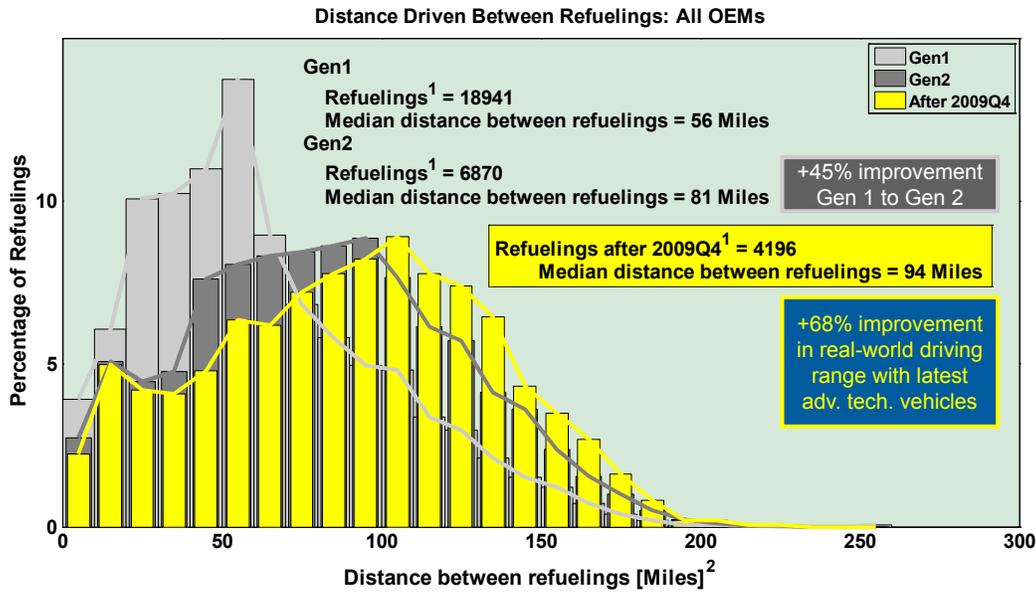

FIGURE 1. Cumulative Vehicles Deployed by Quarter and by Storage Type

vehicles in the project. The data show (Figure 2) a 45% improvement in the median real-world driving range of second-generation vehicles (81 miles) compared to first-generation (56 miles), based on distances driven between more than 25,000 fueling events. In 2010, with continued operation of some second-generation vehicles and the introduction of some improved performance second-generation vehicles, we have seen an increase in the median distance traveled between fuelings to 94 miles. This reflects a 68% improvement in real-world driving range with the latest advanced technology vehicles compared to the first-generation vehicles first introduced in 2005. As previously discussed, all the vehicles are capable of two to three times greater range than this when pushed to their full capabilities with sufficient fueling infrastructure, but the median distance traveled between fuelings is one way to measure the improvement in the vehicles' capability as well as the way in which they are actually being driven. We believe the reason for the increase in median driving distance between fuelings is due to slight improvements in the vehicle capabilities (better efficiency) and in more widespread infrastructure, which enables the vehicle storage tanks to be drawn down closer to empty because drivers are confident they can obtain fuel close by.

- **Fuel Cell Durability:** The Spring 2010 results indicated that the highest average projected team time to 10% voltage degradation for second-generation systems was 2,521 hours, with a multi-team average projection of 1,062 hours. Therefore, the 2,000-hour target for durability was achieved. Since that time, two automotive teams concluded their participation in the project and additional data were acquired on some second-generation vehicles. Improved second-generation vehicles were also introduced to the project. Only two companies now provide durability data, and some vehicles have limited hours on the road, so we will create new durability CDPs in Fall 2011 when

1. Some refueling events are not detected/reported due to data noise or incompleteness.
2. Distance driven between refuelings is indicative of driver behavior and does not represent the full range of the vehicle.

FIGURE 2. Real-World Improvement in Driving Range Between Gen 1, Gen 2, and Latest Advanced Technology Learning Demonstration Vehicles

additional data are available to provide robust analysis and identity protection for all the companies.

- **Vehicle Fueling Rates:** Because of the change in makeup of the automotive and energy teams for the final two years of the project, we separated out the fueling rates for the five years up through 2009 Q4 from the fueling

rates for the year after 2009 Q4 (Figure 3). We found that in the first five years of the project, from more than 25,000 fueling events, the average fill rate was 0.77 kg/min with 23% of the events exceeding DOE’s target of 1 kg/min, representing a 5 kg fill in 5 minutes. Over the last year, from a limited set of 2,766 fills,

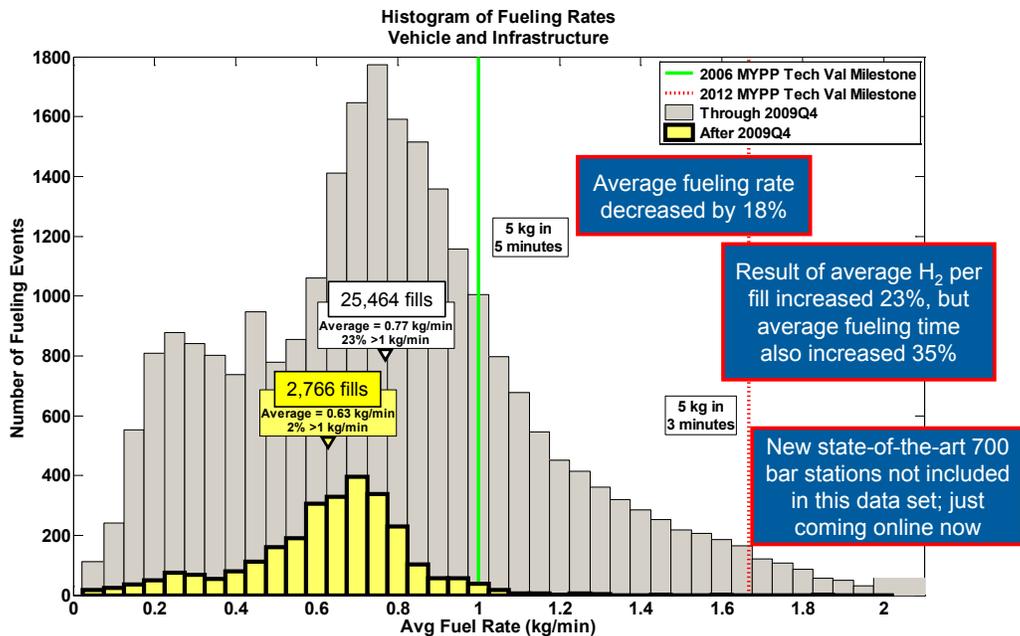

FIGURE 3. Fueling Rate Trends are Monitored as Industry Moves to 700 bar Pressure as Standard

we have observed an average fill rate of 0.63 kg/min with just 2% of the fills exceeding the 1 kg/min target. Several factors explain this 18% drop in fueling rate. The average hydrogen dispensed per fill increased by 23%, but the average fueling time increased by 35%. The root cause is that the hydrogen community is migrating toward 700 bar pressure fueling as the new standard, but the state-of-the-art stations that can achieve a fast and complete fill at this pressure with precooling are just now coming online, and data from those stations were not available through December 2010. Additionally, some 350 bar stations and vehicles that demonstrated fast-fill times have been decommissioned. So this reduction in reported fill rate should be a temporary phenomenon until the new 700 bar station data are included in the dataset later this year. With the new data and analysis results, NREL will be able to document the significant progress that has been made relative to 700 bar infrastructure.

- Hydrogen Fueling Infrastructure Usage Patterns: The final technical result to highlight is the usage patterns of the hydrogen fueling stations within the project over the last year. Figure 4 shows the percentage of hydrogen dispensed by day of the week (bars with left-axis labels) along with the average amount of hydrogen dispensed by day for each of the six stations included in this dataset (curves with right-axis labels). The data show that weekday fueling is still more common than weekend fueling, which had been shown in a previous CDP from the first five years of the project. The graph also shows that two stations have relatively high average throughput (8-14 kg/day); the other four are only lightly used, dispensing 3 kg/day or less on average. This type of result will be useful as we go forward to be able to track the throughput of each station individually and by specific geographic region to better coordinate and advise stakeholders on optimal future vehicle deployments and new station placement.

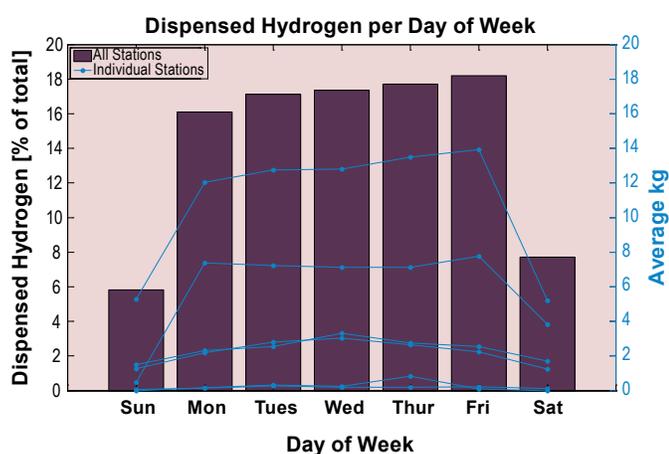

FIGURE 4. New Infrastructure CDP Provides Insight into Specific Fueling Usage Patterns

Conclusions and Future Direction

- Completed the first six years of the seven-year project with 155 vehicles deployed in fleet operation, 24 project fueling stations demonstrated, and no major safety barriers encountered.
- Analyzed data from 460,000 individual vehicle trips covering >3 million miles traveled and 140,000 kg hydrogen produced or dispensed.
- Verified that high fuel cell system efficiency was maintained from Gen 1 to Gen 2 systems, with Gen 2 efficiency at quarter-power of 53%–59%, close to the 60% DOE target.
- Published 85 CDPs to date and made them directly accessible to the public from an NREL website.
- We will create new and update CDPs based on data collected through June 2011 (Fall 2011 CDPs) and present results for publication at the 2011 Fuel Cell Seminar.
- NREL will support DOE's September 2011 milestone to document operation of advanced technology fuel cell vehicles with up to 600 hours of operation.
- We will support original equipment manufacturers, energy companies, and state organizations in California in coordinating early infrastructure plans.
- We will gather and analyze data from a relatively large (100 kg/day on-site production) hydrogen station in Burbank, California, along with many new stations that are being opened in California in 2011 (for example, the Torrance pipeline station and the Fountain Valley tri-generation station).
- NREL will continue to identify opportunities to feed findings from the project back into the Vehicle Technologies and FCT programs and industry R&D activities to maintain the project as a "learning demonstration."
- We will continue to gather data from FCEVs and hydrogen stations through the end of calendar year 2011, when the auto manufacturer Learning Demonstration projects conclude, and publish one final set of results in Spring 2012.
- As the last deliverable from this project, we will write a final comprehensive summary report for publication.
- We will continue to identify and exploit new opportunities to document fuel cell vehicle and hydrogen progress publicly beyond the end of this project.

Project Start Date: October 1, 2004
Project End Date: September 30, 2011

Contribution to Achievement of DOE Technology Validation Milestones

This project contributes to the achievement of the DOE Technology Validation milestones listed below from the Technology Validation section of the Hydrogen, Fuel Cells and Infrastructure Technologies Program Multi-Year Research, Development and Demonstration Plan:

- **Milestone 2:** Demonstrate FCEVs that achieve 50% higher fuel economy than gasoline vehicles. (3Q, 2005)
- **Milestone 4:** Operate fuel cell vehicle fleets to determine if 1,000-hour fuel cell durability, using fuel cell degradation data, was achieved by industry. (4Q, 2006)
- **Milestone 22:** Six stations and two maintenance facilities constructed with advanced sensor systems and operating procedures. (4Q, 2006)

Accomplishments Through Fiscal Year (FY) 2011

GM has accomplished the following project milestones:

- Deployed 60 vehicles demonstrating two generations of GM's proprietary fuel cell technology in various terrains, driving conditions, and climates (see Figure 1).
- Constructed and utilized first-class maintenance and training facilities located in Ardsley, NY; Ft. Belvoir, VA; and Burbank, CA with a satellite hub located in Lake Forest, CA.
- Established retail and retail-like hydrogen stations for public fueling:
 - Six fueling stations in operation spreading across the Eastern and Western regions.
 - Different types of hydrogen generation/delivery options are demonstrated such as delivered compressed gas and on-site electrolysis.
 - Two stations are infrared-capable and able to fast-fill 3+ vehicles back-to-back.
 - Hydrogen quality testing has been completed in both Eastern and Western regions, among the first stations in the U.S. to be tested at 700 bar.
- Shell Hydrogen opened new stations in the New York City metropolitan area at the John F. Kennedy (JFK) airport and in Bronx during 2009. They also commissioned a station in Culver City, California (Los Angeles [LA]). These stations utilize hydrogen compressed gas delivered by truck and dispense hydrogen at 700 bar utilizing equipment supplied by several companies.
- Gathered comprehensive feedback on all elements of customer experience and vehicle performance to guide future FCEV and infrastructure development.

Objectives

GM and energy partner Shell Hydrogen, LLC, will deploy a system of hydrogen fuel cell electric vehicles (FCEVs) integrated with a hydrogen refueling infrastructure to operate under real world conditions. With this deployment GM and Shell Hydrogen will:

- Demonstrate progressive generations of fuel cell system technology.
- Demonstrate multiple approaches to H₂ generation and delivery for vehicle refueling.
- Collect and report operating data.

Technical Barriers

This project addresses the following technical barriers from the Technology Validation section (3.6.4) of the Hydrogen, Fuel Cells and Infrastructure Technologies Program Multi-Year Research, Development and Demonstration Plan:

- (A) Lack of Fuel Cell Electric Vehicle Performance and Durability Data
- (C) Lack of Hydrogen Fueling Infrastructure Performance and Availability Data
- (D) Maintenance and Training Facilities
- (E) Codes and Standards

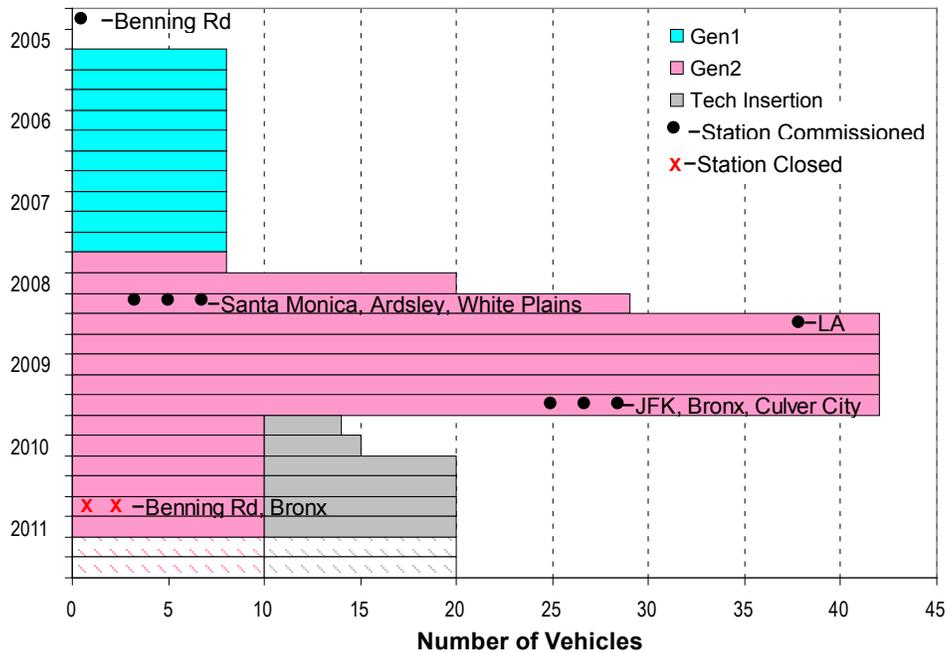

FIGURE 1. GM FCEV and Refueling Station Implementation

- Collected vehicle and station data using automated logbook entry and automated wireless data transfer from vehicles to a data server.
- Conducted and verified extensive cold weather performance testing; additionally, vehicles were deployed in the northeast United States through several winters and performed as customers expected (see Figure 2).
- GM continues to operate and maintain 10 baseline Phase 2 FCEVs through 2011 or until failure.
- Ten additional Phase 2 FCEVs equipped with technology developed during the initial part of Phase 2 were added in 2010 in order to extend learnings. These “Technology Insertion” vehicles were deployed and are accumulating miles (see Figure 3).
- Three fuel cell systems were instrumented with the same hardware as the Technology Insertion vehicles and are running accelerated durability tests on test stands.

Introduction

Over the six-year period to date, the project has made significant progress in support of the long-term goals of DOE’s Technical Validation sub-program. GM has deployed eight Phase 1 FCEVs and 42 of its commercially developed Phase 2 FCEVs and has maintained them through the use of two primary maintenance and training hubs and two additional satellite locations.

For the rest of the project, GM will continue to operate and maintain 10 baseline Phase 2 FCEVs. These baseline Phase 2 FCEVs will continue to operate through 2011 or until failure. The purpose is to demonstrate long stack durability with extended vehicle operating hours (see Figure 4). In addition, 10 new Phase 2 FCEVs were equipped with the most recent materials and controls technology in order to demonstrate the progress made in the project to date. These “Technology Insertion” vehicles are currently deployed and are accumulating miles and generating data for submission to DOE according to the National Renewable Energy Laboratory (NREL) Data Reporting Templates.

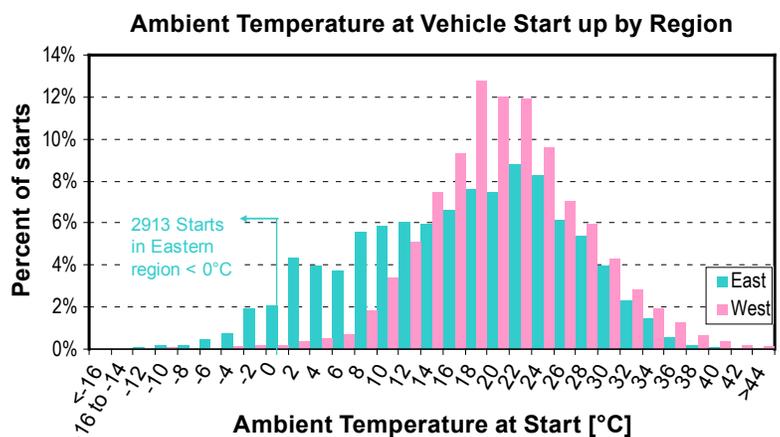

FIGURE 2. 2,913 Vehicle Starts at Ambient Temperatures <0°C

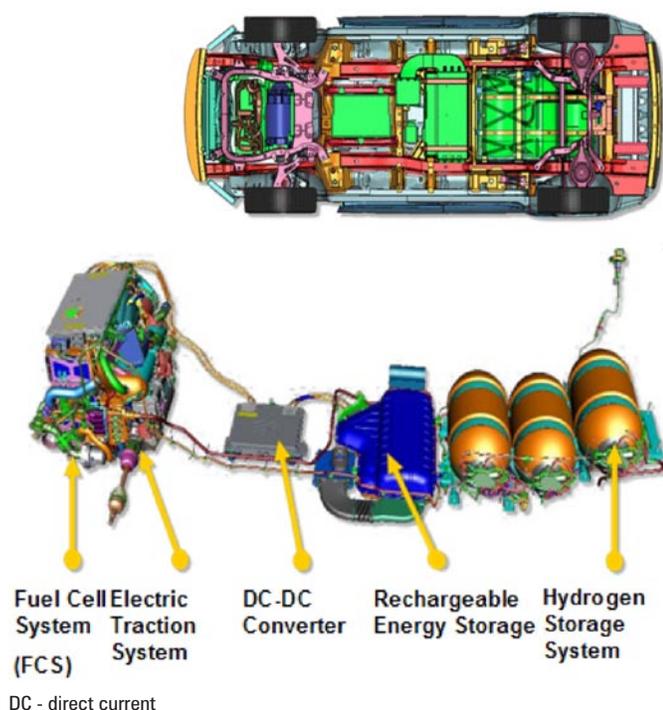

FIGURE 3. Gen2 Chevrolet FCEV with Technology Insertion

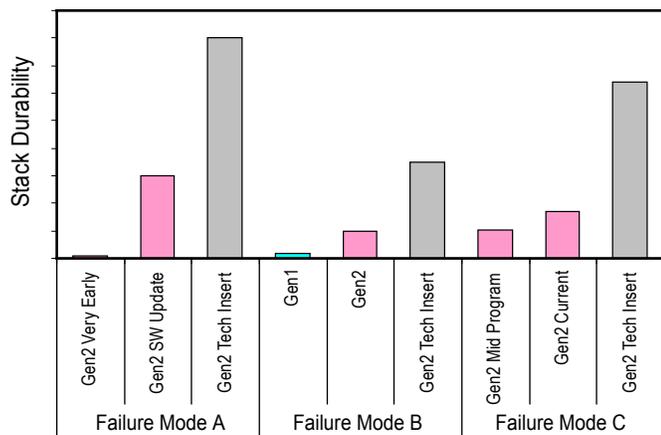

FIGURE 4. Stack Durability Projections: Stack Durability Improves as Successive Iterations Mitigate Failures

Approach

- Demonstrate FCEVs:
 - Deploy FCEVs in various terrains, driving conditions, and climates including cold weather.
 - Demonstrate two generations of fuel cell technology.
- Insert technology with recent advances to test Phase 2 learnings.
- Establish retail-like hydrogen stations for public fueling:

- Install and operate total of six fueling stations on east and west coasts.
- Explore hydrogen generation/delivery options such as electrolysis.
- Set up maintenance and service operations in support of FCEVs:
 - Train personnel in maintenance, fueling, technical support, and safety.
- Generate and report data required under the project:
 - Capture vehicle on-road and dynamometer test data.
 - Capture hydrogen infrastructure production/fueling data.
- Evaluate vehicle performance against targets:
 - Vehicle range, stack durability, cold weather performance.
- Focus on accumulating durability hours:
 - More intensive operation of vehicle fleet.
 - Work with commercial customers.
 - Fuel cell system accelerated durability testing.

Results

Phase 2 FCEVs were launched in the fourth quarter of 2007 in the Eastern and Western regions. All 42 Phase 2 vehicles were deployed by the end of the third quarter of 2008. Thirty-two vehicles completed their deployment at the end of the third quarter of 2009, and 10 baseline Phase 2 vehicles will continue to report data thru the third quarter of 2011 or until failure in order to support stack durability estimates. All 10 Technology Insertion vehicles were deployed by the end of the second quarter of 2010. Twenty project vehicles are now over three years old with 40-50 thousand miles.

Beginning-of-life chassis dynamometer testing was conducted for Phase 2 Chevrolet Equinox FCEVs, which included cold weather tests. Dynamometer testing was completed on one Phase 2 vehicle in September 2009 and one “Technology Insertion” vehicle in June 2010. Another round of dynamometer testing was completed in December 2010 on one Technology Insertion vehicle so the results can be compared to previous testing.

Shell Hydrogen is no longer participating in the project but GM will continue to utilize the Shell stations at JFK, Culver City, West LA, Torrance and the new opening of Newport Beach, CA in 2011. GM will continue to submit refueling data for the Ardsley, NY station, Los Angeles Airport station, and the Culver City station according to the DOE data templates. In addition, the FCEVs may refuel at any of the non-project refueling stations including Honeoye Falls, Rochester Institute of Technology, Monroe County, Fort Belvoir, White Plains, Santa Monica Blvd, Camp Pendleton, University of California, Irvine, and Shell, Torrance.

GM is also anticipating the opening of numerous hydrogen stations in California over the next 18 months, which are supported by Air Resources Board and Energy Commission grants. In total, 18 new and upgraded stations, a majority which will be located in the LA metropolitan area, will be able to support the FCEV fleet.

The hydrogen orientation program for emergency first responders continues to be delivered on request in cities where GM's DOE vehicles operate. To date over 1,500 people trained have been trained and new training sessions continue to be requested on a regular basis.

NextEnergy Center chaired task groups made up of a consortium of industry experts on hydrogen to provide feedback on the National Fire Protection Agency (NFPA) hydrogen codes. Task Groups completed their review of the latest NFPA revision. NextEnergy Center has successfully transferred hydrogen permitting database tools to new website. They coordinated with DOE and its partners to transfer the databases' layout and functionality to DOE ownership, for public benefit. NextEnergy has concluded their participation in the project as of the fourth quarter of 2009.

Three fuel cell systems began running accelerated durability testing in November 2010 and will continue to operate through 2011. In order to accelerate the learnings on the most recent technology stack design, these systems were instrumented with the same hardware as the Technology Insertion vehicles and are running accelerated durability cycles on test stands. These fuel cell systems operate under a stressful, accelerated protocol in order to capture early learnings.

Conclusions and Future Directions

- FCEVs fully meet all functional needs for day-to-day use by individual customers.
- FCEVs are fully functional in sub-freezing cold weather conditions. GM FCEVs exhibited very fast cold-start/driveaway times under sub-freezing temperatures.
- Hydrogen Infrastructure has been demonstrated to be customer friendly in daily use by individual/retail and fleet vehicle operators in a "retail-like" self-service mode.

- Fuel cell stack durability rapidly increased and is expected to meet or exceed the DOE target of 2,000 hours during the completion of the demonstration project.
- GM is taking a significant step by introducing elements of our next generation fuel cell stack and system into a small group of Equinox FCEVs for continued Gen2 operation/demonstration during 2010 and 2011. GM believes that the learnings from the project so far have helped enable materials and operating controls within the fuel cell system that will clearly demonstrate the ability of the Gen2 vehicles to meet and exceed the project stack durability goal of 2,000 hours.
- Furthermore, GM looks forward to a continued relationship and collaboration with NREL in the areas of fuel cell stack and FCEV data analysis methods. GM believes that this work is helping establish a strong foundation for future work throughout the fuel cell industry to develop universally accepted metrics for assessing the performance of fuel cells and FCEV.
- GM will continue to provide data for baseline and Technology Insertion vehicles that are deployed and operating until the end of the project in the fourth quarter of 2011.
- GM will continue to provide lab data from accelerated durability testing to enhance understanding of fuel cell durability until the end of the project in the fourth quarter of 2011.
- GM negotiated its first agreements to purchase fuel "by the kilogram." GM continues to launch new relationships with hydrogen station partners outside original project stations:
 - Rochester Institute of Technology
 - Town of Hempstead, NY
 - SunHydro, Wallingford, CT

FY 2011 Publications/Presentations

1. On May 9, 2011, GM participated and presented at the 2011 U.S. DOE HYDROGEN and FUEL CELLS PROGRAM and VEHICLE TECHNOLOGIES PROGRAM ANNUAL MERIT REVIEW and PEER EVALUATION MEETING.
2. An onsite review meeting with NREL, DOE, and GM personnel is planned for July 2011.

- DTE Energy, Detroit, MI
- NextEnergy, Detroit, MI

Start Date: December 22, 2004
 Projected End Date: September 30, 2011

Fiscal Year (FY) 2011 Objectives

- Record, collect and report data from fuel cell vehicles and the hydrogen fueling operations to validate DOE targets (Table 1).
- Demonstrate the safe installation of hydrogen fueling stations and fuel cell service facilities as well as the safe operation of all fuel cell vehicles (FCVs).
- Continuously update safety manuals and provide training.
- Participate in various working groups to ensure continuous progress towards establishing codes and standards essential for FCV commercialization.
- Raise public awareness of hydrogen technology and demonstration projects.

TABLE 1. Targets

Performance Measure	2009	2015
Fuel Cell Stack Durability	2000 hours	5000 hours
Vehicle Range	250* miles	300* miles
Hydrogen Cost at Station	\$3/gge	\$2-3/gge

gge – gasoline gallon equivalent

Technical Barriers

This project addresses the following technical barriers from the Technology Validation section (3.6.4) of the Hydrogen, Fuel Cells and Infrastructure Technologies Program Multi-Year Research, Development and Demonstration Plan:

- (A) Lack of Fuel Cell Vehicle Performance and Durability Data
- (B) Hydrogen Storage
- (C) Lack of Hydrogen Refueling Infrastructure Performance and Availability Data
- (D) Maintenance and Training Facilities
- (E) Codes and Standards
- (H) Hydrogen from Renewable Resources

Contribution to Achievement of DOE Technology Validation Milestones

This project will contribute to achievement of the following DOE Technology Validation milestones from the Technology Validation section of the Hydrogen, Fuel Cells and Infrastructure Technologies Program Multi-Year Research, Development and Demonstration Plan:

- **Milestone 7:** Validate vehicle refueling time of 5 minutes or less for a 5kg of hydrogen (1kg/min) at 5,000 psi through the use of advanced communication technology (4Q2007).
- **Milestone 8:** Demonstrate the ability to achieve 250 mile range without impacting passenger cargo compartment (4Q2008).
- **Milestone 10:** Validate FCV's 2,000 hour fuel cell durability using fuel cell degradation data (4Q2009).
- **Milestone 12:** Validate cold start capability at -20C (2Q2011).

FY 2011 Accomplishments

- Submitted over 110 compact disks (CDs) of data to demonstrate that fuel cell vehicles are on track to be commercially viable by 2015.
- Successfully completed seven years of external operations of Gen I vehicles (five years past the original target date).
- Maintained smooth operations of the DTE hydrogen station.
- Transitioned FCV activities from research and development (R&D) to mainstream commercial efforts.

- Began customer operations of production-level Gen II vehicles.
- Participated in various working groups to ensure continuous progress with regards to codes and standards.
- Worked with California Energy Commission (CEC), Air Resources Board (ARB) and other original equipment manufacturers (OEMs) to prepare fueling infrastructure.

Introduction

The primary goal of this project is to validate fuel cell technologies for infrastructure, transportation as well as assess technology/commercial readiness for the market. The Mercedes Team, together with its partners, have been testing the technology by operating and fueling hydrogen FCVs under real world conditions in varying climate, terrain and driving conditions. Vehicle infrastructure data has been collected to monitor the progress toward the hydrogen vehicle and infrastructure performance targets of \$2.00-3.00/gge hydrogen production cost and 2,000-hour fuel cell durability. Furthermore, progress has been made to validate cold start capability at -20°C. Finally, to prepare the public for a hydrogen economy, outreach activities have been designed to promote awareness and acceptance of hydrogen technology.

Approach

To achieve the project goals, the Mercedes Team deployed 30 Gen I vehicles into customer hands for real-world operations in various climatic regions of the United States. The Team is also providing data from Gen II vehicles under the similar operations as Gen I vehicles to compare technology maturity during project duration. All vehicles have been equipped with a data acquisition system that automatically collects statistically relevant data for submission to National Renewable Energy Laboratory (NREL), which monitors the progress of the FCVs against the DOE technology validation milestones. The energy partners have installed an infrastructure to provide hydrogen to the Mercedes Team's FCVs and to evaluate the technologies which have the potential to achieve the DOE hydrogen cost targets.

To raise public awareness of hydrogen technology and demonstration projects, the Mercedes Team aligned its communication activities with the goals of the DOE. In addition, project safety was maintained through continued inter-team communication, vehicle and infrastructure training, employee and customer education, and emergency responders training.

Results

Gen I and Gen II FCVs

Although Gen I FCVs were designed for a 2-year operation, A-Class F-CELLs have outperformed engineering expectations as the vehicles have been in full operation for over seven consecutive years. Since the inception of this demonstration project, the Mercedes Team submitted over 110 CDs of Gen I Raw Data to NREL and demonstrated that A-Class F-CELLs exceed the 2,000-hour stack durability target. Through the course of 2010, the Mercedes Team gradually transitioned the vehicle activities from Gen I A-Class to Gen II B-Class FCVs.

The engineering team performed extensive vehicle durability and performance test prior to launching the Gen II B-Class FCVs. First, Gen II vehicles were tested in temperatures ranging from -30°C (Sweden) to 50°C (Death Valley). Furthermore, engineers validated the 250-mile range and cold-start capability down to -17°C while reaching 50% of maximum power within 30 seconds (see Figure 1). Initial test results show Gen II fuel cell stack will most likely meet the 2015 DOE target of 5,000 hours durability.

Prior to deploying Gen II vehicles into customer hands, the Mercedes Team transitioned FCV activities from R&D to mainstream commercial activities. B-Class F-CELL vehicles were incorporated into Mercedes' standard business processes within departments such as warranty, customer assistance, parts and distribution as well as roadside assistance and sales (see Figure 2). Unfortunately, due to limitation of fueling infrastructure, the Mercedes Team had to hand-select Gen II FCV customers to ensure that these individuals were in close proximity to the few hydrogen fueling stations functioning in Southern California. Once the customers were chosen, the customer acquisition process became the responsibility of the dealership. Customers were then required to undergo the same documentation review and qualification processes as typically expected.

FIGURE 1. Cold Weather Testing of Gen II Vehicles

FIGURE 2. Transitioning FCV Efforts from R&D to Commercial Activities

The first Gen II FCVs were delivered to external customers in December of 2010 (see Figure 3). Customers have fuelled and driven B-Class F-CELL vehicles in a variety of regions providing a complete range of climate and traffic conditions from congested city driving to open road highways to rural roads. All Gen II vehicles have been equipped with data acquisition and reporting capability, allowing the Mercedes Team to generate substantial vehicle raw data for submission to NREL.

World Drive

Setting out from Stuttgart in Germany, three B-Class F-CELLS have undertaken a 125-day circumnavigation of the world (see Figure 4). Traveling across four continents and through 14 countries, the three vehicles have confirmed technical maturity of fuel cell technology, as well as the suitability for everyday use of the vehicles. On February 25th, the F-CELL World Drive embarked on the second leg of its tour when three B-Class F-CELL set out from Fort Lauderdale on the East Coast of the United States across eight cities including New Orleans, Miami, San Antonio, Phoenix, Los Angeles, Sacramento, Salem and Seattle. Vehicle raw data generated from the 19,000-mile World Drive has been collected and will be submitted to NREL for analysis.

Codes and Standards

Much progress was made with respect to codes and standards. First of all, a decision was reached with respects to the 70 MPa fueling connector geometry. This subject was reason for intense discussions in working group titled International Organization for Standardization (ISO) 17268, “Gaseous Hydrogen Land Vehicle Refuelling Connection Devices”, which decided to keep the nozzle and receptacle design primarily used in Europe and United States. The same design was selected for Society of Automotive Engineers (SAE) J2600, “Compressed Hydrogen Surface

FIGURE 3. Deployment of Gen II Vehicles to External Customer (Vance van Petten)

FIGURE 4. World Drive Tour in San Francisco, California

Vehicle Fueling Connection Devices”. Consequently, the ISO and SAE teams were able to finalize and harmonize these documents.

J2719, “Information Report on the Development of Hydrogen Quality Guideline for Fuel Cell Vehicles” was recently finalized and is currently up for ballot. After the first version of J2601, “Fueling Protocols for Gaseous Hydrogen Surface Vehicles”, was published in 2010 and became the foundation for many hydrogen refueling protocol discussions, the SAE interface group began working on Version 2 of J2601, which has been expanded to include bus, home and fork lift refueling.

NextEnergy

Serving as voting member and Committee Chair of National Fire Protection Association (NFPA) 2, NextEnergy continued to work on the standard intended to streamline as well as clarify the infrastructure design

and permitting process. During the course of the year, the Team released the first public version of NFPA 2 and is in the process of expanding the document for a 2014 revision cycle. Furthermore, NextEnergy hosted an annual Hydrogen Codes and Standards Conference, which attracted first responders, local officials, hydrogen industry experts, and national code development organizations that provided updates on the latest developments of national and international hydrogen codes and standards. NextEnergy continued to host DOE's Permitting Guide for Hydrogen Technologies and Specifications on its website at www.nextenergy.org.

Outreach and Media

Mercedes-Benz FCVs were on display at several car shows over the course of 2010. The year began with a presence at the Detroit Auto Show where the B-Class F-CELL was part of a green vehicle ride-n-drive. At the Washington Auto Show in Washington, D.C. in February, the F-CELL was incorporated into the MBUSA exhibit. The vehicle was then displayed at the show in New York after being introduced on a nationally broadcast morning talk show. Over the summer of 2010, the F-CELL was also displayed at the Aspen Ideas Festival in Colorado and the U.S. Tennis Open in New York, both of which MBUSA officially sponsors.

At the Detroit Auto Show in January of 2011, one FCV was wrapped with F-CELL World Drive decals and displayed during the press conference when the world tour was announced. The Fuel Cell and Hydrogen Energy Association Conference and Exposition took place in Washington, D.C. in February. Mercedes-Benz was present with a vehicle display which emphasized the lease program in California and the World Drive which had just commenced in Europe.

Fueling Stations and Co-Production Facilities

DTE Hydrogen Technology Park

Since the electrolyzer and dispenser were replaced, the site equipment has run its best for cold weather operations. The electrolyzer ran without any problems and system testing was conducted for all safety circuits. DTE Energy has had a number of tours of the DTE Energy Hydrogen Technology Park both from industry, educational institutions and the general public. Under the auspices of the Department of International Visitor Leadership Program, visitors from Romania, Kosovo and Estonia toured the Technology Park to understand how non-governmental sectors foster innovative and efficient public-private relationship as well as promote community development and corporate citizenship (see Figure 5).

FIGURE 5. Tour of the DTE Energy Hydrogen Technology Park

Preparing for Fueling Infrastructure

As FCVs transition from a demonstration phase to commercialization, the development of well-established hydrogen fueling station network is critical and, as a result, the Mercedes Team has been actively collaborating with other OEMs, government officials and energy partners to build a hydrogen fueling infrastructure:

- Supported ARB/CEC by recommending station specifications, site locations and supplier qualification guidelines.
- Worked with the California Fuel Cell Partnership to develop an action plan detailing strategy for deploying hydrogen fueling stations and FCVs.
- Collaborated with other OEMs to determine and coordinate locations of future fueling stations.

The number of stations is increasing. However, the number of present operational and public stations is the limiting factor for customer selection. The Mercedes Team strongly supports a joint approach of automotive OEMs, energy companies and government agencies such as DOE to overcome the fueling limitation by 2015, the year anticipated for the beginning of commercialization.

Conclusions and Future Directions

Conclusions

- Maintained smooth operations of the DTE station.
- Worked with CEC/ARB and other OEMs to prepare fueling infrastructure.
- Finalized Gen I operations and deployed Gen II F-CELLs to external customers.
- Transitioned FCV activities from R&D to mainstream commercial efforts.

- Participated in various working groups to ensure continuous progress with regards to codes and standards.
- Continued data collection, analysis and reporting.

Future Work

- Maintain and finalize smooth operation of Gen II FCVs.
- Submit final report.
- Continue the development and transition to commercialization of hydrogen FCVs.

Subcontractor:
FuelCell Energy, Danbury, CT

Project Start Date: September 30, 2001
Project End Date: March 31, 2011

Fiscal Year (FY) 2011 Objectives

Demonstrate the technical and economic viability of a hydrogen energy station using a high-temperature fuel cell designed to produce power and hydrogen.

- Complete a technical assessment and economic analysis on the use of high-temperature fuel cells, including solid oxide and molten carbonate, for the co-production of power and hydrogen (energy park concept).
- Build on the experience gained at the Las Vegas H₂ Energy Station and compare/contrast the two approaches for co-production.
- Determine the applicability of co-production from a high-temperature fuel cell for the existing merchant hydrogen market and for the emerging hydrogen economy.
- Demonstrate the concept at a suitable site with demand for both hydrogen and electricity.
- Maintain safety as the top priority in the system design and operation.
- Obtain adequate operational data to provide the basis for future commercial activities, including hydrogen fueling stations.

Technical Barriers

This project addresses the following technical barriers from the Technology Validation section (3.5.4) of the Fuel Cell Technologies Program Multi-Year Research, Development and Demonstration Plan:

- (C) Hydrogen Refueling Infrastructure
- (I) Hydrogen and Electricity Co-production

Contribution to Achievement of DOE Technology Validation Milestones

This project will contribute to achievement of the following DOE Technology Validation milestones from the Technology Validation section of the Fuel Cell Technologies Program Multi-Year Research, Development and Demonstration Plan:

- **Milestone 37:** Demonstrate prototype energy station for 6 months; projected durability >20,000 hours; electrical energy efficiency >40%; availability >0.80. (4Q, 2008)
- **Milestone 38:** Validate prototype energy station for 12 months; projected durability >40,000 hours; electrical energy efficiency >40%; availability >0.85. (1Q, 2014)

FY 2011 Accomplishments

- In July 2010, the Hydrogen Energy Station was shipped from FuelCell Energy's facility in Danbury, CT, to Orange County Sanitation District (OCSD) in Fountain Valley, CA. System installation and tie-ins were completed in August, and first low-load power production from the high-temperature fuel cell unit took place on 13 September 2010. On 20 September 2010, the fuel cell operated for the first time at full load (300 kW) on natural gas feedstock.
- The first coproduction of hydrogen from the Hydrogen Energy Station took place on 20 October 2010.
- Over 1,000 hours of operation in power and (power + hydrogen) modes was completed during the performance period. Hydrogen quality met all performance standards.
- Achieved nominal 54% (power + hydrogen) efficiency of the unit when operating in hydrogen co-production mode.
- On 25 February 2011, the first hydrogen from the Hydrogen Energy Station was sent to the hydrogen fueling station. Initial test fills of fuel cell vehicles at the hydrogen fueling station were completed on 08–10 March 2011.
- The DOE Cooperative Agreement was extended to 30 September 2011.

Introduction

One of the immediate challenges in the development of hydrogen as a transportation fuel is finding the optimal means to roll out a hydrogen-fueling infrastructure

concurrent with the deployment of hydrogen vehicles. The low-volume hydrogen requirements in the early years of fuel cell vehicle deployment make the economic viability of stand-alone, distributed hydrogen generators challenging. A potential solution to this “stranded asset” problem is the use of hydrogen energy stations that produce electricity in addition to hydrogen. To validate this hypothesis, a four-phase project is being undertaken to design, fabricate and demonstrate a high-temperature fuel cell co-production concept. The basis of the demonstration will be a FuelCell Energy DFC[®]-300 Molten Carbonate Fuel Cell modified to allow for the recovery and purification of hydrogen from the fuel cell anode exhaust using an Air Products-designed hydrogen purification system.

The DFC[®] technology is based on internal reforming of hydrocarbon fuels inside the fuel cell, integrating the synergistic benefits of the endothermic reforming reaction with the exothermic fuel cell reaction. The internal reforming of methane is driven by the heat generated in the fuel cell and simultaneously provides efficient cooling of the stack, which is needed for continuous operation. The steam produced in the anode reaction helps to drive the reforming reaction forward. The hydrogen produced in the reforming reaction is used directly in the anode reaction, which further enhances the reforming reaction. Overall, the synergistic reformer-fuel cell integration leads to high (~50%) electrical efficiency.

The baseline DFC[®] power plant (electricity only) is designed to operate at 75% fuel utilization in the stack. The remaining 25% of fuel from the anode presents a unique opportunity for low-cost hydrogen, if it can be efficiently recovered from the dilute anode effluent gases. The recovery and purification of hydrogen from the anode presents several challenges:

- The anode off-gas is a low-pressure, high-temperature gas stream that contains ~10% hydrogen by volume.
- The anode exhaust stream must be heat integrated with the fuel cell to ensure high overall system efficiency.
- The parasitic power used for purification must be optimized with the hydrogen recovery and capital cost to enable an economically viable solution.

Approach

A hydrogen energy station that uses a high-temperature fuel cell to co-produce electricity and hydrogen will be evaluated and demonstrated in a four-phase project. In Phase 1, Air Products completed a feasibility study on the technical and economic potential of high-temperature fuel cells for distributed hydrogen and power generation. As part of the Phase 1 analysis, three different high-temperature fuel cells were evaluated to determine the technology most suitable for a near-term demonstration. FuelCell Energy's DFC[®]-300 technology was selected for concept development. In Phase 2, a process design and cost estimate were completed for the hydrogen energy station that integrates the high-temperature fuel cell with a

pressure swing adsorber (PSA) system selected and designed by Air Products. Economics were developed based on actual equipment, fabrication, and installation quotes as well as new operating cost estimates. High-level risks were identified and addressed by critical component testing. In Phase 3, a detailed design for the co-production system was initiated. The system was fabricated and shop tested. Prior to shipping to the field, the entire system was installed at FuelCell Energy's facility in Danbury, CT for complete system check-out and validation. In Phase 4, the system will be operated on municipal waste water derived biogas at OCSD, Fountain Valley, California, under a 3-year program with the California Air Resources Board, with co-funding by the South Coast Air Resources Board. DOE will receive six months of data from the initial operating phase to validate the system versus DOE and economic performance targets.

Results

Figure 1 shows the process flow diagram for the Hydrogen Energy Station. Methane (in this case, from natural gas) is internally reformed at the fuel cell anode to hydrogen and carbon dioxide. The fuel cell operates near 600°C and uses molten carbonate electrolyte as the charge carrier. Heated air is combined with the waste gas from the hydrogen purification system and oxidized. These resultant waste gases are fed to the cathode. The fuel cell cathode converts waste gas carbon dioxide to the carbonate charge carrier to complete the fuel cell circuit. The fuel cell stack generates a direct current voltage, which is then converted to alternating current (AC) by an inverter in the electrical balance of plant. The system produces 480 VAC, 60 Hz, and a nominal 300 kW without hydrogen co-production. Excess carbon dioxide and water leave the cathode as exhaust, and heat can be recovered from these exhaust gases.

About 70 to 80% of the hydrogen is converted to power, and some hydrogen remains available for recovery. The anode exhaust gas is cooled and sent to a water-gas shift catalytic reactor to convert most of the carbon monoxide present in the stream to hydrogen and carbon dioxide. After an additional cooling step, this gas stream is then compressed and sent to the PSA system. The PSA uses adsorbents to remove carbon monoxide, carbon dioxide, and water to produce a high-purity hydrogen stream. The waste gas from the PSA is catalytically oxidized and returned to the cathode. The PSA system can also be placed in stand-by mode to stop hydrogen production and allow for maximum power production by the DFC[®] system, thereby improving the system efficiency and economics.

In late 2008, the Hydrogen Energy Station was installed at FuelCell Energy's facilities in Danbury, CT for a system check-out and validation of performance on natural gas and simulated digester gas. This testing had several key objectives, including the demonstration of variable production of both electricity and hydrogen, optimization of the process control system and overall controls philosophy, and testing and development (if needed) of systems that respond to

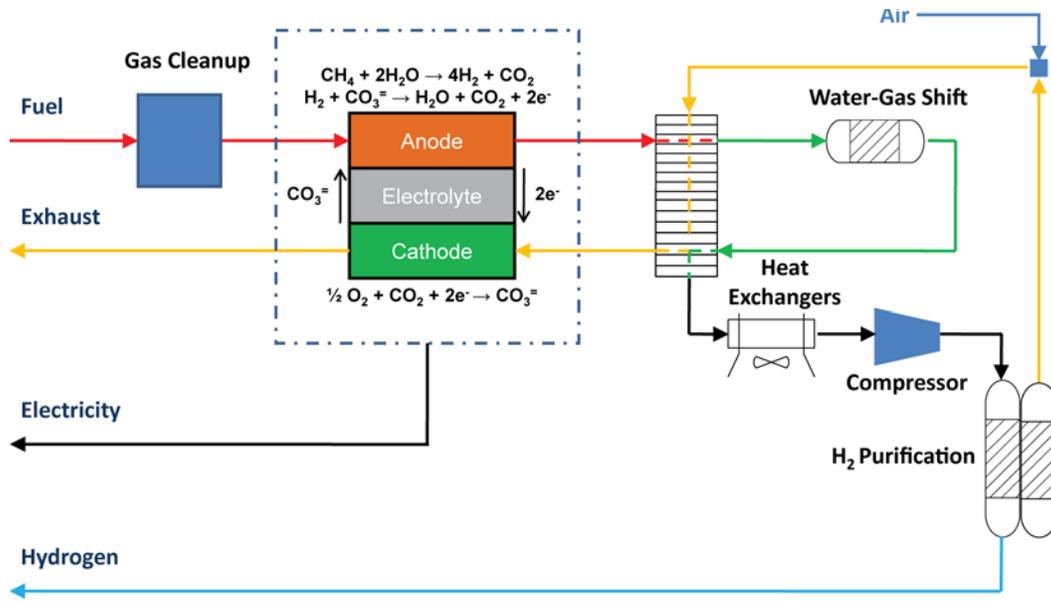

FIGURE 1. Hydrogen Energy Station Process Flow Diagram

upset conditions. The operation and control of the system, including automated integration and de-integration of the PSA from the balance of plant, was excellent.

In June 2010, the Hydrogen Energy Station was disassembled and prepared for shipment from Danbury, CT to the Orange County Sanitation District wastewater treatment plant in Fountain Valley, CA. The system was delivered in early July, and installation and tie-in work

was completed in August 2010. A photograph of the installation at OCSD is provided in Figure 2. Following commissioning activities, the DFC® -300 was brought online on 13 September 2010, and full-load operation on natural gas was achieved on 20 September 2010.

The hydrogen purification system was then commissioned, and initial co-production of hydrogen from the Hydrogen Energy Station on natural gas at OCSD

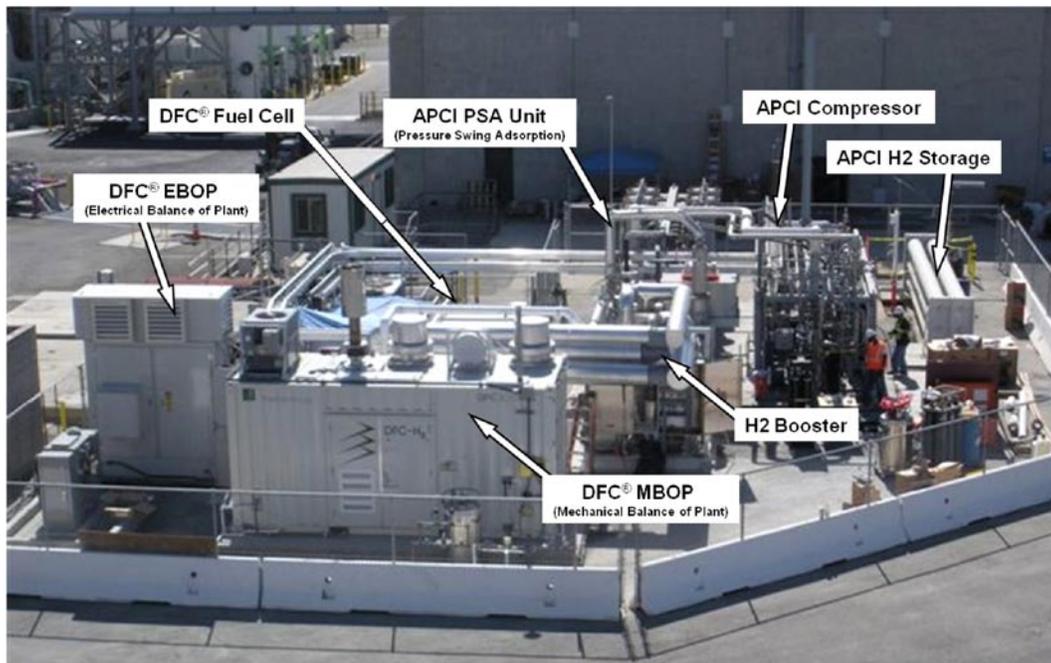

FIGURE 2. Hydrogen Energy Station Installation at Orange County Sanitation District

occurred on 20 October 2010. A heat and material balance was performed during this initial operating period, and a (power + hydrogen) efficiency of 54.5% was calculated. A summary of the heat and mass balance is provided in Figure 3.

Following this initial operating performance, power quality issues associated with the local grid within the wastewater treatment plant were identified. The power conditioning unit/inverter associated with the fuel cell showed unusual behavior in its ability to connect with the local grid, and changes were required to match the highly inductive power factor (0.6 to 0.8) and larger voltage sags (5-10%). On 14 December 2010, a module within the inverter was damaged by an electrical fault. Repairs and determination of the root cause were completed by FuelCell Energy and their supplier of the inverter, and the fuel cell was restarted in February 2011. Hydrogen co-production was then brought online, and the first hydrogen from the Hydrogen Energy Station was sent to the hydrogen fueling station; the fueling station (sized at 100 kilograms per day) and a gas cleanup skid to remove contaminant species such as sulfur from the anaerobic digester gas supply are being installed under a second DOE project (Cooperative Agreement No. DE-FC36-05GO85026). Initial test fills

of fuel cell vehicles at the hydrogen fueling station were successfully completed on 8-10 March 2011.

Conclusions and Future Direction

- The Hydrogen Energy Station was shipped to OCSD and brought online. Initial performance in power and (power + hydrogen) modes was excellent. Issues with site power quality led to an electrical fault within the inverter of the fuel cell; repairs were completed, and operation resumed in February 2011.
- Operation on anaerobic digester gas from the wastewater treatment facility is expected to begin in May 2011 following installation of the gas cleanup skid that will remove trace contaminant species from the biogas. Data will be provided to DOE for the first six months of operation under a 3-year program sponsored by the California Air Resources Board and South Coast Air Quality Management District.

on in-service fuel economies between 5 and 7 miles per kilogram, hybrid FCBs can achieve a range between 250 and 350 miles per fill. This efficiency depends on duty-cycle. There are no major issues with lost cargo/passenger space on FCBs because the tanks are typically mounted on the roof; however, the added weight of the system limits the number of standing passengers allowed on the buses.

FY 2011 Accomplishments

- Published final reports on current-generation performance and operational data on five full-size hybrid FCBs in revenue service in the United States.
- Published first report on next-generation FCB in service in Palm Springs, CA.
- Began data collection on next-generation fuel cell system in revenue service at two additional transit agencies.

Fiscal Year (FY) 2011 Objectives

- Determine the status of fuel cell bus (FCB) technologies in transit applications by evaluating them in real-world service.
- Coordinate with the Department of Transportation's Federal Transit Administration (FTA) on the data collection for the National Fuel Cell Bus Program and with international work groups to harmonize data-collection methods and enable the comparison of a wider set of vehicles.

Technical Barriers

This project addresses the following technical barriers from the Technology Validation section of the Fuel Cell Technologies Program Multi-Year Research, Development, and Demonstration Plan:

- (A) Lack of Fuel Cell Vehicle Performance and Durability Data
- (C) Lack of H₂ Fueling Infrastructure Performance and Availability Data
- (D) Maintenance and Training Facilities

Technical Targets

Milestone 18: Validate fuel cell durability of 3,500 hours, 300+ mile range and fuel cell stack power density of 1.5 kW/L. (4Qtr 2012) By the end of April 2011, NREL had documented three FCB fuel cell systems with operation in excess of 6,000 hours with no major repairs. One of these systems has logged more than 9,000 hours in service. Based

Introduction

Transit agencies continue to aid the FCB industry in developing and optimizing advanced transportation technologies. These in-service demonstration programs are necessary to validate the performance of the current generation of fuel cell systems and to determine issues that require resolution. Using fuel cells in a transit application can help accelerate the learning curve for the technology because of the high mileage accumulation in short periods of time. During the last year, major progress was made in improving fuel cell durability; however, more work is needed to improve reliability, increase durability to meet the needs of transit agencies, lower capital and operating costs, and transition the maintenance to transit staff.

Approach

NREL uses a standard evaluation protocol to provide:

- Comprehensive, unbiased evaluation results of advanced technology vehicle development and operations.
- Evaluations of hydrogen infrastructure development and operation.
- Descriptions of facility modifications required for the safe operation of FCBs.
- Detailed results on fuel cell systems for buses and the requisite hydrogen infrastructure to complement the light-duty demonstrations and further DOE goals.

The evaluation protocol includes two levels of data: operation and maintenance data on the bus and

infrastructure, and more detailed data on the fuel cell, system, and components. The first set of data is considered non-sensitive and is obtained mainly from the transit fleet. The analysis, which consists of economic, technical, and safety factors, focuses on performance and use, including progress over time and experience with vehicle systems and supporting infrastructure.

The detailed data are collected with cooperation from the bus/fuel cell system manufacturers and are considered highly sensitive. Results include aggregate data products that protect each manufacturer’s specific data. To date, NREL has collected this type of data from two fuel cell manufacturers. Aggregate results will be published if and when enough data are available to protect each company’s identity and source data.

Results

During FY 2011, NREL completed data collection and analysis on current-generation FCB demonstrations at three transit agencies in the United States: SunLine Transit Agency in Thousand Palms, California; Connecticut Transit (CTTRANSIT) in Hartford, Connecticut; and AC Transit in Oakland, California. The first two of these evaluations were funded by DOE, and the third evaluation was covered by funding from FTA. Under DOE funding, NREL also began collecting data on next-generation FCBs at three agencies: City of Burbank, California; AC Transit; and SunLine. NREL published results from the current-generation FCBs. A summary of selected results is included in this report, followed by an overview and early results of the next-generation FCBs being evaluated.

The current-generation FCBs in service at AC Transit, CTTRANSIT, and SunLine were all of the same basic design: Van Hool 40-ft buses with ISE Corp. hybrid-electric drives and UTC Power fuel cell power systems. As reported

in the previous annual report, the manufacturer partners used the early performance data to validate the systems and further develop the product and components. Beginning in November 2007, UTC Power replaced the fuel cell power systems in each of the five buses with newer versions that were developed incorporating many of the lessons learned from the previous operation of these FCBs. NREL collected operational and performance data on these FCBs and conventional baseline buses at each agency. Table 1 provides a summary of results from the operation at each agency after the new fuel cells were installed. Data from the baseline buses are included in the table. Note that the data from the buses at AC Transit ended in September 2010. These three buses were retired during that year; however, two of the fuel cell power systems were transferred into the bodies of the next generation buses and continue to accumulate hours.

Figure 1 shows the fuel economy of the buses at each location in miles per diesel gallon equivalent. (Note that the baseline buses at SunLine are compressed natural gas [CNG] buses – SunLine does not operate diesel buses.) The FCBs at the three locations showed fuel economy improvement ranging from 48% to 133% when compared to diesel and CNG baseline buses. This figure also illustrates the variability of the results from fleet to fleet. The results are affected by several factors, including duty-cycle characteristics (average number of stops, average speed, and idle time). Also, the diesel buses at AC Transit do not have air conditioning, but the fuel cell buses do. The CTTRANSIT diesel buses operate at twice the average speed of the FCB operating on the Star Shuttle Route, which causes significantly lower fuel economy for the FCB compared to the fuel economies at the other two agencies.

One measure of reliability for the transit industry is miles between roadcall (MBRC). A roadcall is the failure of an in-service bus that causes the bus to be replaced on route

TABLE 1. Summary Data Results for Early Generation FCBs

Vehicle data	AC Transit		CTTRANSIT		SunLine	
	FCB	Diesel	FCB	Diesel	FCB	CNG
Number of buses	3	6	1	3	1	5
Data period	Nov 07 - Sep 10	Jan - Dec 07	Jan 08 - Jan 11	Aug 07 - Oct 09	Apr 08 - Jan 11	Nov 08 - Jan 11
Number of months	~34	12	37	27	34	15
Total fleet miles	194,288	266,337	46,558	259,547	67,553	636,954
Average miles per month	2,136	3,699	1,258	3,204	1,987	4,718
Total FC hours	19,802	--	7,187	--	9,448	--
Fuel economy (mi/kg)	5.93	--	4.83	--	7.15	3.11
Fuel economy (mi/diesel eq. gal)	6.70	4.20	5.46	3.68	8.08	3.47
Average speed (mph)	9.8	not available	6.5	not available	13.0	not available
Availability	66%	85%	62%	85%	70%	92%

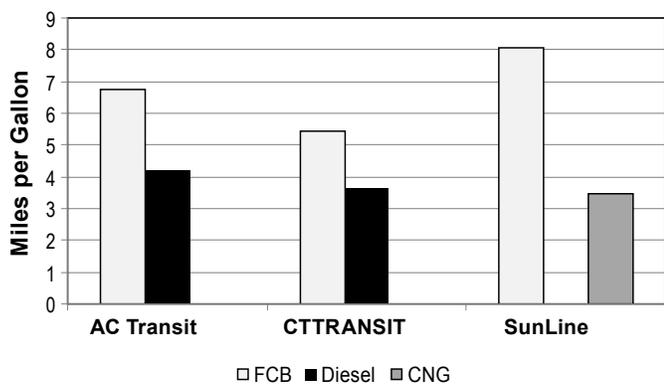

FIGURE 1. Fuel Economy Comparison by Fleet (Diesel Equivalent)

or causes a significant delay in schedule. NREL typically reports MBRC for the entire bus and for the propulsion system separately to show the reliability of the FCBs. Over time, these FCBs have been shown to have propulsion system MBRCs that are much lower than MBRCs for the baseline buses. This is not necessarily due to the fuel cell power system, but instead has mostly been because of traction battery issues. To illustrate the improvement in reliability of the fuel cell power system in the buses, Figure 2 tracks the combined fuel cell system MBRC since the buses went into service. The shading in the middle of the chart marks the time during which all five FCBs had the newer version fuel cell systems installed. In the 2010 annual report, NREL reported this upward trend for the average fuel cell system MBRC. The trend has continued to show improvement; increasing from 21% to 37% with the newer version system. The two leading fuel cell systems have accumulated significant hours without any major repairs (one is over 9,000 hours and a second is over 8,000 hours).

NREL began collecting data on several next-generation FCBs during the year. Figure 3 shows the newest fuel cell bus in service at SunLine. This bus is a New Flyer 40-ft. bus with a Bluways hybrid system, Ballard fuel cells, and lithium ion batteries. NREL completed its first report on this bus in service at SunLine. As of November 2010, the bus had accumulated more than 9,000 miles and 818 hours on the fuel cell with an average fuel economy of 5.75 miles per kg. This is nearly two times higher than the fuel economy for the baseline CNG buses.

NREL began collecting data on other next generation fuel cell buses at the following transit agencies:

- City of Burbank – one battery dominant, plug-in hybrid FCB developed by Proterra using Hydrogenics fuel cells and lithium titanate batteries.
- AC Transit – 12 next-generation Van Hool FCBs with a hybrid system integrated by Van Hool and UTC Power fuel cell power system.
- Additional sites funded by the FTA include four buses at CTRANISIT and a bus in service in Columbia, SC.

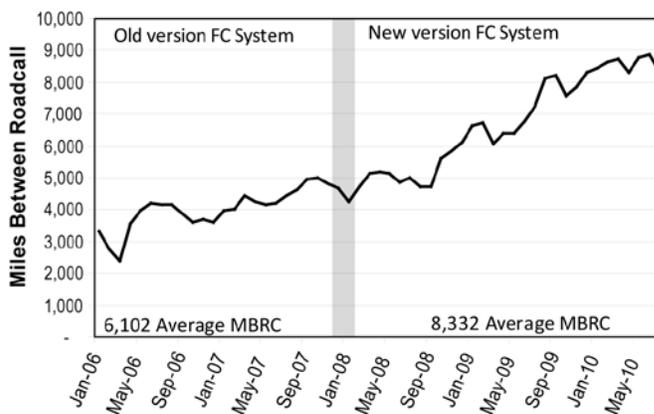

FIGURE 2. Miles between Roadcall for the Fuel Cell Propulsion System (12-Month Rolling Average)

FIGURE 3. SunLine's Newest Fuel Cell Bus

Conclusions and Future Direction

First-generation fuel cell propulsion systems in buses have continued to show progress in fuel economy and longer durability. Changes incorporated into the design based on early lessons learned have resulted in fuel cells that are nearing a target of 10,000 hours. While this is encouraging, there are still challenges to overcome before fuel cell buses can match the current standard of diesel bus performance. These include:

- Lowering costs of purchasing, operating, and maintaining buses and infrastructure.
- Increasing durability/reliability of the fuel cell systems and other components to match transit needs.
- Transferring all maintenance to transit personnel.

Future work by NREL includes:

- Collecting, analyzing, and reporting on performance data for next-generation hydrogen-fueled vehicles in service at the following sites:

- Bay Area FCB Demonstration led by AC Transit
- SunLine
- City of Burbank
- Additional sites as funding allows
- Investigating reliability, durability, and life cycle of FCBs as a part of ongoing evaluations; these efforts complement the DOE light-duty fuel cell electric vehicle demonstrations.
- Coordinating with FTA to ensure harmonized data-collection efforts for the National Fuel Cell Bus Program.
- Coordinating with national and international FCB demonstration sites.

Contract Number: DE-FC36-05GO85026

Working Partners/Subcontractors:

- University of California, Irvine (UCI), Irvine, CA
- National Fuel Cell Research Center (NFCRC), Irvine, CA

Project Start Date: August 1, 2005

Project End Date: December 31, 2011

Contribution to Achievement of DOE Technology Validation Milestones

This project will contribute to achievement of the following DOE Technology Validation milestones from the Technology Validation section of the Fuel Cell Technologies Program Multi-Year Research, Development and Demonstration Plan:

- **Milestone 23:** Total of 10 stations constructed with advanced sensor systems and operating procedures. (1Q, 2008).

FY 2011 Accomplishments

- Completed construction of, and vehicle test fills, at the hydrogen pipeline fueling station (350 and 700 bar dispensing) in Torrance, CA.
- Completed 9-month deployment of 350 bar mobile station (HF-150) in Placerville, CA.
- Completed construction of and began initial vehicle test fills at the hydrogen pipeline fueling station (350 and 700 bar dispensing) in Fountain Valley, CA.

Fiscal Year (FY) 2011 Objectives

Demonstrate a cost-effective infrastructure model in California for possible nationwide implementation:

- Design, construct and operate seven hydrogen fueling stations.
- Collect and report infrastructure data.
- Document permitting requirements and experiences.
- Validate expected performance, cost, reliability, maintenance, and environmental impacts.

Implement a variety of new technologies with the objective of lowering costs of delivered H₂:

- New Delivery Concept (NDC).
- High pressure/high purity clean up equipment.

Technical Barriers

This project addresses the following technical barriers from the Technology Validation section (3.6.4) of the Fuel Cell Technologies Program Multi-Year Research, Development and Demonstration Plan:

(C) Hydrogen Refueling Infrastructure

Introduction

Air Products and Chemicals, Inc. is leading a comprehensive, multiyear project to demonstrate a hydrogen infrastructure in California. The specific primary objective of the project is to demonstrate a model of a “real-world” retail hydrogen infrastructure and acquire sufficient data within the project to assess the feasibility of achieving the nation’s hydrogen infrastructure goals. The project will help to advance hydrogen station technology, including the vehicle-to-station fueling interface, through consumer experiences and feedback. By encompassing a variety of fuel cell vehicles, customer profiles and fueling experiences, this project is obtaining a complete portrait of *real market needs*. The project is also opening its stations to other qualified vehicle providers at the appropriate time to promote widespread use and gain even broader public understanding of a hydrogen infrastructure. The project is engaging major energy companies to provide a fueling experience similar to traditional gasoline station sites to foster public acceptance of hydrogen.

Approach

Work over the course of the project was focused in multiple areas. With respect to the equipment needed, technical design specifications were written, reviewed, and finalized. Both safety and operational considerations were

a part of this review. After finalizing individual equipment designs, complete station designs were started including process flow diagrams and systems safety reviews. Material quotes were obtained, and in some cases, depending on the project status and the lead time, equipment was placed on order and fabrication was started. Consideration was given for expected vehicle usage and station capacity, standard features needed, and the ability to upgrade the station at a later date.

In parallel with work on the equipment, discussions were started with various vehicle manufacturers to identify vehicle demand (short- and long-term needs). Discussions included identifying potential areas most suited for hydrogen fueling stations, with focus on safe, convenient, fast-fills. These potential areas were then compared and overlaid with suitable sites from various energy companies and other potential station operators. Work continues to match vehicle needs with suitable fueling station locations. Once a specific site has been identified, the necessary agreements can be completed with the station operator and expected station users. Detailed work can begin on the site drawings, permits, safety procedures and training needs. Once stations are brought online, infrastructure data will be collected and reported to DOE using Air Products' eRAM system. Feedback from station operators will be incorporated to improve the station user's fueling experience.

Results

The first of the hydrogen fueling stations within the California Hydrogen Infrastructure Project continued operation at the NFCRC at UCI. The capability for fueling vehicles with gaseous hydrogen at 350 bar, involving the installation of a 1,500 gallon horizontal liquid hydrogen tank, 2 kg/hr compressor skid, storage for 50 kg of hydrogen, and a dual dispenser for both 350 and 700 bar hydrogen was brought onstream in August of 2006. The 700 bar system, including the installation of a booster compressor, was commissioned in February of 2007. Based on a 50% compressor on-stream factor, the station has the capacity to dispense 24 kg/day or approximately six cars per day. The station continues to see high usage, with daily throughput often reaching 50 kg/day. A proposal by Air Products to expand the station to 100 kg/day capacity was selected for support by the California Energy Commission. A photograph of the dispensing system is provided in Figure 1.

The world's first fueling station supplied by a hydrogen pipeline completed construction in early 2011 to demonstrate a low-cost, reliable supply of hydrogen. A site in the Torrance, CA area in proximity to an existing Air Products hydrogen pipeline was developed by Shell Hydrogen. A 4 kg/hr compressor skid and a total of 100 kg of 7,777 psig storage and 20 kg of 15,000 psig storage have been provided. This station dispenses hydrogen according to SAE TIR-J2601. Hydrogen purification technology has been deployed for the first time in this application to demonstrate the production of an ultra-pure hydrogen stream from the

Photo by Lorin Humphries

FIGURE 1. UCI 350/700 Bar Hydrogen Fueling Station

industrial-grade pipeline supply. Two dual dispensers for both 350 and 700 bar hydrogen have been installed, and four vehicles can be filled simultaneously. Based on a 50% compressor on-stream factor, the station will have the capacity to dispense 48 kg/day or approximately 12 cars per day. When starting with full storage, six cars can be filled in succession. A photograph of the completed dispenser area is provided in Figure 2. Vehicle test fills were completed in March 2011, and a station opening ceremony was planned for May 2011.

The HF-150 (shown in Figure 3) is ideal for small fleet fueling and offers the advantages of being a highly reliable, cost-effective, and automated fueling system that can be easily installed. The HF-150 maintains about 150 kg of gaseous hydrogen at 6,600 psig. It can dispense approximately 80 to 90 kg before needing to be refilled. In December 2010, Air Products completed a 9-month deployment of an HF-150 mobile fueller at the District Office of the U.S. Forest Service in Placerville, CA.

Air Products was selected under California Air Resources Board Solicitation 06-618, "Establish Demonstration Hydrogen Refueling Stations," to install a renewable-based hydrogen fueling station and cleanup system for anaerobic digester gas at Orange County Sanitation District in Fountain Valley, CA. Under this project, hydrogen will be produced utilizing the Hydrogen Energy Station concept being developed under a second DOE project (Cooperative Agreement No. DE-FC36-01GO11087). The statement of work for this project was modified to include the procurement and installation of a

FIGURE 2. Torrance, CA Hydrogen Pipeline Fueling Station

FIGURE 4. Fountain Valley Renewable Hydrogen Station

FIGURE 3. Air Products HF-150 Hydrogen Fueler – Placerville, CA

hydrogen fueling station (sized at 100 kilograms per day) and of a gas cleanup skid to remove contaminant species such as sulfur from the anaerobic digester gas that will be fed to the Hydrogen Energy Station. The fueling station includes compression, storage, and dispensing of hydrogen at 350 and 700 bar according to SAE TIR-J2601. Construction of the fueling station was completed in November 2010, and hydrogen produced from natural gas by the Hydrogen Energy Station was sent to the storage tubes in the fueling

station on 25 February 2011. Initial test fills of vehicles were performed in March 2011. A photograph of the fueling station area, with the dispenser in the foreground and the balance of fueling station equipment in the background, is provided in Figure 4. Delivery of the clean-up system for the anaerobic digester gas is expected in May 2011, after which production of renewable hydrogen for use in the fueling station is expected to begin in June 2011.

Conclusions and Future Directions

Planned future work includes:

- UCI Fueling Station – continue operation of both 350 and 700 bar systems.
- Torrance Pipeline Fueling Station – continue operation of both 350 and 700 bar systems.
- Fountain Valley Renewable Station – begin operation of (1) clean-up system for anaerobic digester gas and (2) 350 and 700 bar systems.
- Infrastructure Data Acquisition, Analysis and Delivery – report data to DOE.

FY 2011 Publications/Presentations

1. A presentation regarding the overall project status was given at the DOE Annual Merit Review Meeting (May 2011).

Contract Number: DE-FC51-02R021399 A008

Project Start Date: June 29, 2009 (Final Agreement
with State of Hawaii)

Project End Date: September 30, 2012

Fiscal Year (FY) 2011 Objectives

Island of Hawaii (Big Island)

- Install hydrogen dispensing infrastructure at Hawaii Volcanoes National Park (HAVO) on the Big Island of Hawaii (hydrogen provided under a separate program: “Hydrogen Energy Systems as a Grid Management Tool”).
- Support the operations of the National Park Service (NPS) hydrogen plug-in hybrid electric vehicle (PHEV) shuttle buses through September 2012.
- Conduct engineering and economic analysis of HAVO bus operations on different routes, grades, elevations and climatic conditions.
- Validate fuel cell system performance in harsh environments including high SO₂ concentrations.
- Attract new partners and applications for the Big Island hydrogen infrastructure.
- Conduct outreach to local authorities and the general public regarding hydrogen infrastructure.

Oahu

- Support operations of the General Motors (GM) Equinox Fuel Cell Vehicle (FCV) Hawaii demonstration program in partnership with the Office of Naval Research.
- Install a Powertech hydrogen production, storage, and dispensing system at Marine Corps Base Hawaii (MCB Hawaii);

- Procure and operate a lightweight hydrogen delivery trailer to support fueling requirements; and
- Conduct engineering and economic analysis of GM FCV fueling operations.

Technical Barriers

This project addresses the following technical barriers from the indicated sections of the April 2009 edition of the Fuel Cell Technologies Program Multi-Year Research, Development and Demonstration Plan:

Technology Validation, Section 3.6.4

- (A) Lack of Fuel Cell Vehicle Performance and Durability Data
- (C) Lack of Hydrogen Refueling Infrastructure Performance and Availability Data
- (H) Hydrogen from Renewable Resources

Hydrogen Safety, Section 3.8.4

- (H) Lack of Hydrogen Knowledge by Authorities Having Jurisdiction

Technical Targets

This project will contribute to the following DOE milestones from sections of the Multi-Year Research, Development and Demonstration Plan:

Technology Validation section 3.6.6 Milestones

- **Milestone 34:** Complete power park demonstrations and make recommendations for business case economics. (2Q, 2008) Our HAVO system will utilize electrolytic hydrogen produced at a nearby geothermal plant and delivered by tube trailer from the geothermal plant to HAVO. The geothermal hydrogen production plant is funded by a DOE/Naval Research Laboratory (NRL) project (not part of Power Park) and the Power Park is leveraging this investment. Our MCB Hawaii system will support the early deployment of a small fleet of GM Equinox FCVs. Data will be collected to evaluate cost and technical performance of the MCB Hawaii and HAVO systems.

FY 2011 Accomplishments

- Signed an implementation agreement with the State of Hawaii (DOE funds via State Energy Office) contracting HNEI as the project “Implementing Partner” on behalf of the State of Hawaii.
- Secured State of Hawaii \$1.2 million cost share funds via Kolohala Holdings LLP.

- Completed a hydrogen fueling station specification.
- Obtained Kilauea Military Camp (KMC) approval and support as the site of the fueling station.
- Completed background noise survey at the KMC site.
- Assisted HAVO to develop a noise specification for the fueling station.
- Assisted HAVO to secure bus funding from NPS (\$1 million) and from the State of Hawaii (\$600,000).
- Re-scoped the project to support the GM Hawaii Equinox FCV rollout at MCB Hawaii.
- Completed factory acceptance of the Powertech system and demonstrated compatibility with GM Equinox FCVs.
- Developing several memorandums of agreement among project partners:
 - HAVO
 - KMC
 - MCB Hawaii
- Initiated actions to relocate the Powertech integrated hydrogen production and dispensing system to MCB Hawaii on Oahu.
- National Environmental Protection Act (NEPA) approval for the HAVO site.
- NEPA approval for the MCB Hawaii site.
- Obtained funding and initiated actions to upgrade the Powertech station to 700 bar fast-fill to support GM Equinox FCVs.
- Developed the infrastructure specifications for MCB Hawaii.
- Selected the contractor to install infrastructure at MCB Hawaii.
- Secured an additional \$600,000 in state funding for the MCB Hawaii infrastructure.
- Purchased the hydrogen delivery tube trailer for use on Oahu.

Introduction

The Hawaii Hydrogen Power Park (Power Park) was established to support the DOE Technology Validation sub-program. The Power Park is funded by the DOE through the Hawaii Department of Business, Economic Development and Tourism's Strategic Industries Division, in its role as the Hawaii State Energy Office, with the University of Hawaii's Hawaii Natural Energy Institute as the implementing partner, with the objective to conduct engineering and economic validation of pre-commercial hydrogen technologies. Power Park is supporting the testing and validation of hydrogen fueling system technologies on the Big Island of Hawaii and Oahu, including production utilizing renewable energy, compression, storage, delivery, and dispensing to hydrogen vehicles. In parallel, the HAVO

is planning to acquire, initially, two battery-dominant fuel cell PHEV shuttle buses. The source of HAVO funds is from the Department of Transportation through the NPS Alternative Transportation in the Parks and Public Lands Program. It is intended to support HAVO's hydrogen fueling requirements with the infrastructure developed in the Power Park. In 2011 the scope of the project was expanded to include support for the GM Equinox FCV demonstration on Oahu. The fueling station originally planned for HAVO is being reallocated to the MCB Hawaii on Oahu. A fueling dispenser will be installed at HAVO and supplied with hydrogen produced at the Puna Geothermal Ventures (PGV) geothermal plant under a separate award and delivered by lightweight hydrogen delivery trailers to HAVO.

Approach

Due to the expanded scope of the project, activities are now being conducted on the Big Island of Hawaii and on Oahu. The approach is to install hydrogen fueling stations at each of the sites and conduct fueling operations to support small fleets of fuel cell vehicles. On the Big Island a compressor fueling dispenser will be installed at the KMC facility located at HAVO to support two PHEV battery-dominant fuel cell shuttle buses that will be used to shuttle visitors around the park. The hydrogen will be supplied via tube trailers from the PGV geothermal site. This leverages a non-related DOE/NRL project that is utilizing electrolyzers as a potential grid load management system while producing hydrogen that can be used for transportation.

On Oahu the project will install a fully integrated hydrogen production, storage, and dispensing system at MCB Hawaii. The station will be used to support the operation of a small fleet of GM Equinox FCVs. Initially dispensing hydrogen at 350 bar, the station will be upgraded to 700 bar utilizing Office of Naval Research funding.

Results

Legal and Insurance

This project relies on the installation of major hydrogen systems and infrastructure to enable the demonstration of a variety of technologies in an integrated system and a real-world environment. The installation of infrastructure in the private community requires interfacing with local authorities having jurisdiction and covers a variety of subject areas relating primarily to safety in form of permitting and related codes and standards, fire fighting and first responders training, and, as we have experienced in this project, legal issues involving risk management, liability, indemnification and insurance coverage. Multiple partners add to the complexity of developing legal agreements and we have experienced a significant educational requirement to ensure a high level of comfort with these projects among all the parties. While significant progress in working through these issues has been made, it is incremental and time-consuming,

and introduces delays to the project schedule. HNEI has identified this as a systemic issue and raised it with the DOE. Apparently many hydrogen projects have reported similar experiences. HNEI has proposed that DOE work on developing a systemic solution that includes working with the insurance industry. Initial meetings have been held and follow-on meetings have been planned. In the meantime, HNEI continues to draft appropriate agreements that address indemnification and liability concerns.

Program Development

Due to changed circumstances, it was decided that the best use of project resources would be to leverage a new separately-funded project entitled Hydrogen Energy Systems as a Grid Management Tool that will produce hydrogen at the PGV geothermal plant. The new plan will deliver hydrogen from PGV to HAVO using lightweight composite hydrogen delivery trailers towed by a light-duty truck. Fueling operations will be accomplished by a compressor-fill hydrogen dispenser connected to the hydrogen tube trailer. These changes make use of lower cost electricity and provide a clear linkage to producing hydrogen from a renewable energy source. The original Powertech fueling station will be deployed to the MCB Hawaii on Oahu to support the deployment of a fleet of GM Equinox FCVs. This 350 bar station will be upgraded to provide a 700 bar fast-fill capability using funds provided by the Office of Naval Research. This change resulted in the requirement to apply for approvals from the DOE and the State of Hawaii, amend project documentation, and submit new NEPA forms.

Technical

During this reporting period HNEI conducted a successful factory acceptance trial of a turnkey Powertech hydrogen production and dispensing system at Powertech in Vancouver. The factory acceptance trial was supported

by GM which deployed an Equinox FCV to prove compatibility of the FCV with the fueling station. Several fueling and de-fueling operations were conducted to ensure proper communications between the fueling station and the vehicle's onboard monitoring and control system. The design of the MCB Hawaii supporting site improvement infrastructure was completed, and a request for quotes was issued for the "turn-key" installation of the site improvements. Further technical progress will be accomplished after all legal agreements are in place.

Conclusions and Future Directions

Oahu

- Execute remaining memorandums of agreement with project partners.
- Complete the MCB Hawaii infrastructure site improvements.
- Install the Powertech system at MCB Hawaii.
- Upgrade the Powertech system to 700 bar fast-fill.

Island of Hawaii (Big Island)

- Install a hydrogen 350 bar dispensing system at HAVO.
- Deliver geothermal hydrogen to HAVO with tube trailer.
- Support HAVO bus operations.
- Collect and analyze fueling station and vehicle data.
- Seek opportunities for expansion of fleets and/or additional hydrogen infrastructure.

Contract Number: DE-FC36-04GO14225

Subcontractors:

- EnerFuels, Inc., West Palm Beach, FL
- Florida Solar Energy Center, Cocoa, FL
- SRT Group, Inc., Miami, FL
- University of Florida, Gainesville, FL
- Florida State University, Tallahassee, FL
- Bing Energy, Inc., Tallahassee, FL
- Florida Institute of Technology, Melbourne, FL
- University of South Florida, Tampa, FL

Project Start Date: October 1, 2004

Project End Date: June 30, 2012

*Congressionally directed project

Fiscal Year (FY) 2011 Objectives

Develop Florida's hydrogen and fuel cell infrastructure and to assist the U. S. Department of Energy in its hydrogen and fuel cell programs and goals by:

- Developing hydrogen and fuel cell infrastructure.
- Creating partnerships for applied technology demonstration projects.
- Sponsoring research and development in the production, storage and use of hydrogen and in the use and application of fuel cells.
- Facilitating technology transfers between the public and private sectors to create, build and strengthen high-growth potential, high technology companies.
- Developing industry support or potential for widespread applications.
- Developing unique hydrogen/fuel cell university-level education programs.

Technical Barriers

This project addresses technical barriers from the Technology Validation section of the Fuel Cell Technologies Program Multi-Year Research, Development and Demonstration Plan as follows:

- (A) Lack of Fuel Cell Vehicle Performance Data and Durability Data
- (B) Hydrogen Storage
- (C) Lack of Hydrogen Refueling Infrastructure and Availability Data
- (H) Hydrogen from Renewable Resources
- (I) Hydrogen and Electricity Co-Production

Contribution to Achievement of DOE Technology Validation Milestones

This project will contribute to achievement of the DOE Technology Validation milestones 6, 11, and 24 from the Fuel Cell Technologies Program Multi-Year Research, Development and Demonstration Plan.

- Validate on-board cryo-compressed storage system on a technology development vehicle achieving 1.5 kWh/kg and 1.0 kWh/L. (2Q, 2007)
- Decision to proceed with Phase 2 of the learning demonstration. (2Q, 2010)
- Validate a hydrogen cost of \$3.00/gge (based on volume production). (4Q, 2009)

Accomplishments

- Project has solicited proposals to conduct work.
- Project composed of 12 projects with three projects completed.
- Presently have nine active projects – one old project with new demo site, three new projects started on April 1, 2010, and five new projects started on December 1, 2010.

Introduction and Approach

The FHI is a hydrogen and fuel cell program funded for the purpose of developing a hydrogen and fuel cell infrastructure. The FHI program has operated by funding individual projects which conduct the research, development and demonstration activities. Each of the individual projects are approved by DOE before work can begin. Following the change in operation and management of FHI, the project

management began the process of allocating the remaining funds (~\$2.5 million) to new projects and finishing and/or completing old projects. At the present time, there are nine active projects with four in fuel cells, three in hydrogen and two in hydrogen and fuel cells.

Individual Project Descriptions

With the above background, the nine active projects are briefly described in the following sections.

Task 2. Hydrogen Technology Rest Area – Michael Fuchs, EnerFuel, Inc.

The project objectives are to design, construct, and demonstrate a 10 kW_{net} polymer electrolyte membrane fuel cell (PEMFC) stationary power plant operating on methanol, to achieve an electrical energy efficiency of 32% and to demonstrate transient response time <3 ms. The yearly accomplishments successfully incorporated the existing inverter and fuel cell systems into the design of the charging station, completed system testing at EnerFuel prior to delivery to Florida Atlantic University. Final activities are to operate the charging station for a period of three months, determine overall electrical efficiency, document system transient response to load changes, and determine overall performance and effectiveness of charging station.

Task 7. Chemochromic Hydrogen Leak Detectors for Safety Monitoring – Dr. N. Mohajeri and Dr. N. Muradov, FSEC

The objective of this project is to develop and demonstrate a cost-effective, high specific chemochromic (visual) hydrogen leak detector for safety monitoring at any facility engaged in handling and use of hydrogen. The work will lead to two classes of chemochromic hydrogen sensors, an irreversible one and a reversible one. The yearly activities have evaluated the performance (sensitivity) of the sensors at different hydrogen concentrations in air (from 1 to 100 vol%) and found no interference with other reducing gases (CO, NH₃, CH₄, H₂S).

For the irreversible sensors, the results are several new chemochromic pigments that have been synthesized and tested. Three new formulations show faster kinetics with the response time for PK-2-31NM49 chemochromic sensor being 80% faster than first generation irreversible pigment. For the reversible sensors, the results are 20 novel Mo-, W-, V-based chemochromic formulations that have been synthesized and tested and the effect of the co-catalyst/activator on the rate of coloration in presence of hydrogen has been determined.

Task 8. Development of High Efficiency Low Cost Electrocatalysts for Hydrogen Production and PEM Fuel Cell Applications – Dr. C. Huang and Dr. M Rodgers, FSEC

The objectives of this project are to develop nanosized and high efficiency electrocatalysts based on alloys and

metal-metal oxides composites. The new catalysts will be evaluated for their activity toward H₂ evolution via water electrolysis as well as oxygen reduction reaction for PEMFC applications. The relevance of this project is that Pt metal catalysts are the most effective PEMFC catalysts, but their use is impeded by costs, efficiency, and life span for oxygen reduction reaction. Approaches to overcome these limitations involve reducing Pt loading while maintaining high performance of catalysts. The methods of increasing Pt activity include optimization of the size and shape of the Pt particles, alloying Pt with other metals, and depositing catalyst particles only where the electrocatalytic reaction takes place.

In PEMFC applications, for Pt in a catalyst layer to be active, it must be deposited at the “three phase reaction zone.” This can be done by sputtering deposition or pulse electrodeposition. The approach of catalyst preparation is to electrodeposit catalyst particles on three phase zones by coating a carbon microporous and Nafion® layer on carbon paper. A rotating disk electrode (RDE) technique is used to carry out pulse electrodeposition. The results indicate that Pt catalyst prepared by the pulse electroplating technique show higher activities than that of a commercial catalyst. The prepared catalysts can also be used for H₂ production via water electrolysis with higher efficiency. The future work is to synthesize alloy-based electrocatalysts and to perform catalyst characterization.

Task 9. Understanding Mechanical and Chemical Durability of Fuel Cell Membrane Electrode Assemblies – Dr. D. Slattery, FSEC

The objective of this project is to increase the knowledge base of the degradation mechanisms for membranes used in PEMFCs. The yearly results are that fluoride emission of 1100 equivalent weight perfluorinated sulfonic acid membranes can be reduced by the addition of cerium oxide to the membrane, the formulation of the ceria changes its efficacy, the improvements in durability are dependent on the ceria concentration, and improved cell durability can be achieved by using Pt-Co/C rather than Pt/C results and the addition of phosphotungstic acid to the electrode sublayer reduced membrane degradation.

The planned future work is to continue analysis of cerium oxide to determine the source of improvements, to conduct accelerated durability tests and compare the results to the Fenton tests, to determine the amount and location of Pt in the membrane by electron microscopy tests, to determine by cell testing the effect of heteropoly acid on platinum migration to identify performance losses and then optimize the sublayer electrode to reduce these losses.

Task 10. Production of Low-Cost Hydrogen from Biowaste (HyBrTec™) – Mr. R. Parker, SRT Group, Inc.

The objective of this project is to conduct research and development on biowaste reactor (called HyBrTec™) that

does not have the problems associated with conventional biowaste-to-fuel processing using an anaerobic digester. This new reactor will reduce the cost and improve energy efficiency. The project approach is to produce hydrogen bromide (HBr) from wet-cellulosic waste (co-produces carbon dioxide and thermal energy) and then use electrolysis to dissociate hydrogen bromide ($E^\circ = 0.555$ V) producing recyclable bromine and hydrogen (endothermic), and follow with combustion in order to react hydrogen with the more energetic oxygen ($E^\circ = 0.1229$ V), affording a theoretical process efficiency of 100%.

The project is in its initial stages of development and the accomplishments to date are that the reactor/electrolysis vessel is designed, the preliminary bromination experiments at $<200^\circ\text{C}$ are favorable, and assembly of a bench-top 500 ml prototype reactor/electrolysis vessel has begun. The future work is to conduct the high temperature HBr electrolysis, integrate bromination/electrolysis to determine optimum temperature and pressure, perform analysis of by-products and conduct preliminary economic analysis.

Task 11. Development of a Low-Cost and High-Efficiency 500 W Portable PEMFC System – Drs. J. Zheng, R. Liang, and W. Zhu, Florida State University, Mr. H. Chen, Bing Energy, Inc.

The project research objectives are to demonstrate new catalyst structures comprised of high conducting buckpaper and Pt catalyst nanoparticle coated at or near the surface of buckpaper and to demonstrate efficiency, durability improvement, and cost reduction using carbon nanotube buckpaper-based electrodes.

The technical approach is to use carbon nanotubes that are suspended on buckpaper, to use electrodeposition of Pt, and to characterize the catalysts by cyclic voltammetry of a PEMFC using the buckpaper. The results have developed an innovative fuel cells assembly, taken images of two-layered Pt/buckpaper and determined cell performance. Current results have been achieved by Florida State University/Bing Energy, Inc. for electrocatalyst and membrane electrode assemblies. These results show the meeting of some DOE goals with the future expectation of meeting all DOE goals.

Task 12. Hydrogen and Fuel Cell Technology Academic Program - Mary Helen McCay, PhD, PE, Kurt Winkelmann, PhD, Florida Institute of Technology, Melbourne Florida

This project has the objective to develop a hydrogen and fuel cell technology (HFCT) academic program at the Florida Institute of Technology (FIT) in Melbourne, FL. The resulting program will allow students to follow hydrogen technology from introduction to long-term applications, obtain a basic understanding, redirect their current technology focus as a means for new career options, measure students' gains in knowledge of hydrogen as an energy source and satisfy the need for hydrogen technology graduates. The approaches to accomplish the program goals are to establish a Masters Degree area of specialization,

develop modules for existing undergraduate courses, support senior design and capstone projects and prepare hydrogen-themed general chemistry lab experiments.

The FIT HFCT program began on December 1, 2011 and is in its initial stages of development. The technical accomplishments and progress are the hydrogen knowledge and opinion surveys have been administered to mechanical and aerospace engineering and chemistry students, graduate courses and modules are under development, and hydrogen-themed general chemistry lab experiments are designed to improve students' views about chemistry and their knowledge about hydrogen as an alternative energy source. The anticipated results are a strong curriculum on hydrogen and fuel cell technology that will assist undergraduate students in furthering their understanding of hydrogen and fuel cell technology, to offer graduate students a career path into renewable energy and prepare students for entry into research and other positions related to hydrogen technology.

Task 13. Design and Development of an Advanced Hydrogen Storage System using Novel Materials – Drs. E. Stefanakos, D. Goswami, and A. Kumar, University of South Florida

The project objectives are to design and develop novel conducting polymeric nanomaterials for on-board hydrogen storage with a system gravimetric capacity of 5.5 wt% or greater and with complete reversible hydrogen storage characteristics at moderate temperature ($<100^\circ\text{C}$).

The proposed approach is to perform the synthesis of polyaniline (PANI), a solid state hydrogen storage material, and to modify the synthesis parameters for optimized storage capabilities. The major challenge is to develop polymer nanostructures that can store hydrogen at room temperature, and be reversible for many cycles. The preliminary work has used PANI nanostructures for H_2 storage and studies the morphological effects of H_2 cycling on PANI nanofibers that are electrospun. This work shows the PANI nanostructures combine physisorption and chemisorption, reversible storage of >3 wt% is possible at room temperature, and reversible storage of <10 wt%, is possible at 100°C .

Task 14. Advanced HiFoil™ Bipolar Plates – Mr. J. Braun, EnerFuel, Inc.

The project objectives are to address cost and durability barriers for high temperature proton exchange membrane fuel cells (HTPEMFC) by providing a low cost, easy to form, corrosion-resistant laminate bipolar plate having high thermal conductivity and improved mechanical strength/crack resistance. The existing commercial bipolar plate technology includes machined expanded graphite composite plates and gold-coated stainless steel plates – all costly. The new EnerFuel patent-pending laminate technology has shown excellent performance and corrosion resistance. A HTPEMFC stack was tested for 1,000 hours with no failure, and thermal cycled from room temperature to 200°C over 10,000 times with no failure.

The expected results are demonstration and characterization of advanced fuel cell materials that combine the strength of metal with the corrosion resistance of graphite, for use as a bipolar plate in HTPEMFCs operating at 200°C.

Conclusions and Future Directions

FHI has completed three projects and continues work on nine projects. All project budget funds are committed and the projects are scheduled for completion in 2012.

*Congressionally directed project

- **Milestone 28.** Validate the cost of compression, storage and dispensing at refueling stations and stationary power facilities to be <\$\$.80/gge of hydrogen. (4Q, 2013)

FY 2011 Accomplishments

- Identified, procured, and installed station electrolyzer: HySTAT-A 1000D-30-10. **(M26)**
- Identified, procured, and installed 350 bar compressor: PDC-4-1000-6500. **(M26, M28)**
- Identified, procured, and installed two 700 bar compressors: Hydro-Pac C12-60-10500LX. **(M26, M28)**
- Identified, procured, and installed three 350 bar storage tanks: CPI-20 kg. **(M26, M28)**

Introduction

The College of Engineering, Computer Science, & Technology at California State University, Los Angeles (CSULA) as part of its energy curriculum is building a sustainable hydrogen station to teach and demonstrate the production and application of hydrogen as the next generation of fully renewable fuel for transportation. The funding is applied for the acquisition of the core hydrogen station equipment: electrolyzer, compressors and hydrogen storage.

Approach

The CSULA hydrogen station will deploy the latest technologies with the capacity to produce 60/kg/day, sufficient to fuel 15 vehicles or a bus and five more vehicles. The station will be utilizing a Hydrogenics electrolyzer, first and second stage compressors capable of fast filling at 10,000 psi (700 bar), 60 kg of hydrogen storage, water purification and equipment cooling system. The station will be grid-tied and powered by 100% renewables.

The station will also be used as an applied research facility for equipment testing and verification, testing of fuel purity and dispensing accuracy. Another primary function of the station is to introduce hydrogen as a safe transportation fuel through public education and local partnerships.

Results

The equipment under this funding is purchased through General Physics. The equipment integration and station design is through Weaver Construction. The team consisting

Fiscal Year (FY) 2011 Objectives

- Procure core equipment for the CSULA hydrogen station.
- Install/integrate the core equipment.

Technical Barriers

This project addresses the following technical barriers from the Technology Validation section of the Fuel Cell Technologies Program Multi-Year Research, Development and Demonstration Plan:

- (C) Lack of Hydrogen Refueling Infrastructure Performance and Availability Data
- (D) Maintenance and Training Facilities
- (E) Codes and Standards

Contribution to Achievement of DOE Technology Validation Milestones

This project will contribute to achievement of the following DOE milestones from the Technology Validation section of the Fuel Cell Technologies Program Multi-Year Research, Development and Demonstration Plan:

- **Milestone 26.** Validate refueling site stationary storage technology provided by the delivery team. (4Q, 2012)

of representatives from CSULA, Weaver and General Physics have bi-weekly meetings to regularly discuss the construction progress.

The grant provided funding for acquisition of the core hydrogen station equipment: electrolyzer, compressors and hydrogen storage. The compressors and storage arrived in November 2010, see Figure 1. The electrolyzer and other units were moved onsite on their foundations in January 2011, see Figure 2. After the payments for the equipment from DOE and non-federal funding cost share, the project will be essentially complete, see Figure 3.

FIGURE 1. CSULA Hydrogen Fueling Facility, Compressors and Storage, January 2011

FIGURE 2. CSULA Hydrogen Fueling Facility, Electrolyzer Delivery, January 2011

FIGURE 3. CSULA Hydrogen Fueling Facility, Current Status, June 2011

Conclusions and Future Directions

This year work concentrated on procuring and integrating the core equipment for the CSULA Hydrogen station. This task was completed in January 2011. The construction has continued and the expected station commissioning is in the August-September 2011. Future research into station/vehicle performance is planned.

VIII. SAFETY, CODES & STANDARDS

VIII.0 Safety, Codes & Standards Sub-Program Overview

The Safety, Codes & Standards sub-program supports research and development (R&D) that provides critical information needed to define requirements and close gaps in codes and standards and safety to enable the widespread commercialization and safe deployment of hydrogen and fuel cell technologies. In Fiscal Year (FY) 2011, the sub-program focused on continuing to identify measures to reduce the risk and mitigate the consequences of potential incidents that could hinder the commercialization of these technologies.

The sub-program promotes collaboration among government, industry, codes and standards development organizations (CDOs and SDOs), universities, and national laboratories in an effort to harmonize regulations, codes, and standards (RCS) both internationally and domestically. Communication and collaboration among codes and standards stakeholders is emphasized in order to maximize the impact of the sub-program's efforts and activities in international RCS. The sub-program is leading a round-robin testing effort by the Regulations, Codes and Standards Working Group of the International Partnership for Hydrogen and Fuel Cells in the Economy (IPHE), which aims to harmonize high-pressure tank testing protocols required for tank certification. Additionally, DOE continues to work with the Department of Transportation to support its role as the U.S. representative to the United Nations ECE-WP29/GRPE to develop a global technical regulation for hydrogen-fueled vehicles.

The sub-program supports the development and implementation of best practices and procedures to ensure safety in the operation, handling, and use of hydrogen and fuel cell technologies for Program-funded projects. To achieve this goal, the sub-program utilizes the expertise of the Hydrogen Safety Panel, which evaluates the safety plans and practices of Program-funded projects. The Safety Panel provides recommendations on the safe conduct of project work as well as lessons learned and best practices that can be of broad benefit to the Program.

In addition, extensive external stakeholder input—from the fire-protection community, academia, automobile manufacturers, and the energy, insurance, and aerospace sectors—is used to create and enhance safety knowledge tools for emergency responders and authorities having jurisdiction. The sub-program has renewed its emphasis on ensuring the continual availability of safety knowledge tools, distributed via an array of media outlets to reach the largest number of safety personnel possible.

Goals

The sub-program's key goals are to provide the validated scientific and technical basis required for the development of codes and standards, to promulgate safety practices and procedures to allow for the safe deployment of hydrogen and fuel cell technologies, and to ensure that best safety practices underlie all research, technology development, and market deployment activities supported by the Hydrogen and Fuel Cells Program.

Objectives

The sub-program's key objectives are to:

- By 2015, enable development and promulgation of codes and standards essential for widespread market entry of hydrogen and fuel cell technologies, and by 2020, enable the completion and harmonization of all essential domestic and international RCS. These objectives will be achieved through:
 - Conducting R&D efforts to provide data needed to define requirements in developing codes and standards.
 - Developing and validating test measurement protocols and methods to support and facilitate international harmonization of codes and standards.
 - Coordinating with international stakeholders.
- On an ongoing basis, develop and implement practices and procedures for the safe conduct of all projects funded by the Hydrogen and Fuel Cells Program.
- On an ongoing basis, ensure that safety-related information resources and lessons learned are widely available to first responders, authorities having jurisdiction, and other key stakeholders.

FY 2011 Status

The sub-program continues to support R&D to provide the technical basis for codes and standards development with projects in a wide range of areas, including fuel specification, separation distances, materials and components compatibility, and hydrogen sensor technologies. Utilizing the results from these R&D activities, the sub-program continues to actively participate in discussions with SDOs such as the National Fire Protection Association (NFPA), International Code Council, SAE International, Canadian Standards Association (CSA), and International Organization for Standardization (ISO) to promote domestic and international collaboration and harmonization of RCS. Figure 1 gives an overview of the timeline of codes and standards development work:

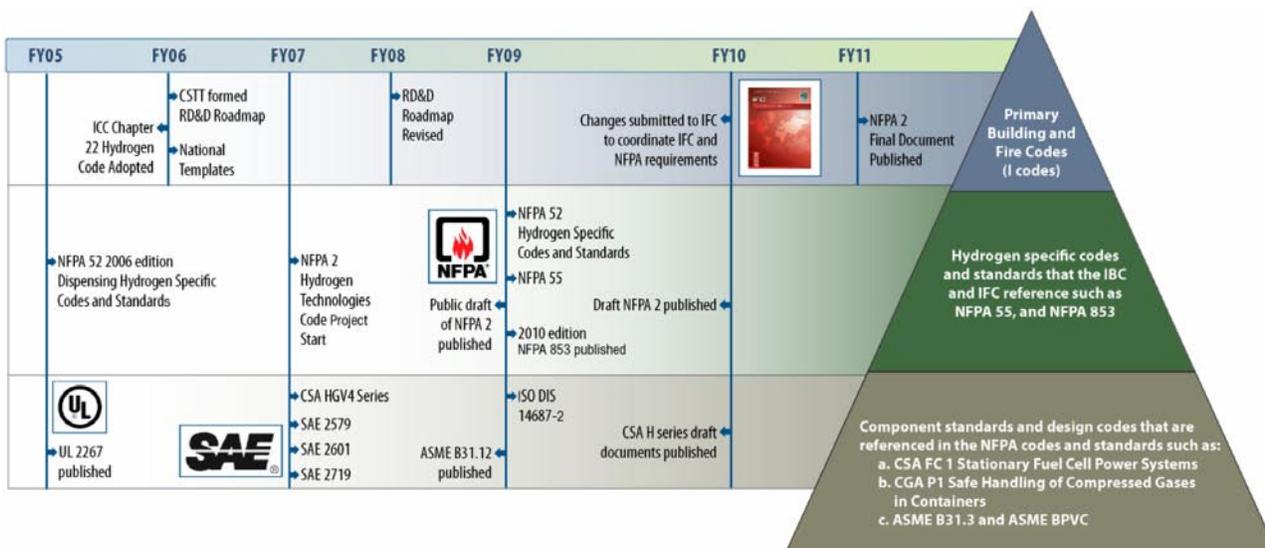

FIGURE 1. Overview of Codes and Standards Development Work

FY 2011 Accomplishments

Hydrogen Sensors

- Completed testing of laboratory and pre-commercial sensor prototypes, including comparison of mixed potential and impedance modality in laboratory prototypes; completed fabrication of multiple pre-commercial sensor prototype devices for testing (National Renewable Energy Laboratory [NREL]).
- Performed an assessment of hydrogen sensors and their related targets, through a Sensor Workshop, which enabled the Program to update sensor performance targets set in 2007. (Workshop attendees included representatives from industry, national laboratories, and sensor manufacturers; the workshop minutes contain updated sensor performance targets based on the comprehensive input provided by the attendees.)
- Completed round-robin testing on hydrogen sensors, in coordination with the European Commission's Joint Research Center. (Data derived from this testing, including performance, sensitivity, and reversibility was presented at the 2011 International Conference on Hydrogen Safety and validates the test approaches and methodologies.)

Fuel Quality

- Quantified the impact of fuel contaminants—for example, completed multiple tests on proton exchange membrane fuel cells under various conditions using calibrated quantities of NH_3 , CO , and H_2S .
- Hydrogen fuel quality standard SAE J2719 was published. Developed and validated ASTM International techniques for measuring key constituents in the fuel.

Indoor Fueling

- Validated a model of unintended hydrogen releases and delayed ignition deflagration during indoor refueling of hydrogen-powered lift trucks. The validated model is being used in the development of requirements in NFPA 2, including specification of room volume and ventilation requirements (Sandia National Laboratories [SNL]).

Coordination of Codes and Standards Development, Domestic and International

- Harmonized and compared risk-informed approaches for the specification of separation distances in NFPA2 2011 edition codes and initiated an effort to harmonize NFPA codes with ISO 20100 codes.
- Developed procedures for performance-based pressure testing of storage vessels with gaseous hydrogen to be included in CSA HPIT1, SAE J2579, and the Global Technical Regulations Phase I (SNL).
- Held a forum on high-pressure hydrogen tanks in Beijing to identify key gaps in high-pressure vessel testing and qualification.
- Launched a new International Energy Agency (IEA) task on hydrogen safety (SNL, in partnership with Natural Resources Canada). The work plan has been approved and the initial meeting was held in Germany in April 2011. This new task (IEA Hydrogen Implementing Agreement Task 31) is a collaboration of experts from more than 12 countries.

Hydrogen Effects in Materials

- Hosted the Hydrogen Compatible Materials Workshop at SNL. Workshop participants included more than 40 international experts from industry, universities, and research laboratories. Results have been published in proceedings, which describe the prioritized research pathways for overcoming the science, engineering, and codes and standards barriers related to hydrogen compatibility with various materials. High-priority research pathways include crack initiation and crack propagation in materials in a hydrogen environment.
- Validated procedures for testing low-alloy steel materials and tanks used in lift trucks. It was found that engineering predictions of cycle-life for low-alloy pressure vessels have been lower than the actual results shown by full-scale performance testing (SNL).

- Published four additional chapters on plain carbon ferritic steels and nickel alloys in the *Hydrogen Compatibility of Materials Technical Reference*, focused on the assessment of materials compatibility for component designs and test methodologies.

Hydrogen Safety Panel

- The Hydrogen Safety Panel reviewed 60 safety plans for projects within the Program's R&D portfolio and American Recovery and Reinvestment Act-funded fuel cell deployments. Panel teams conducted safety review site visits for four Program-funded projects and participated in a 30% design review of the new Energy Systems Integration Facility at NREL (Pacific Northwest National Laboratory).
- Six project safety evaluation reports were issued. Overall results for these safety evaluations indicate that over 90% of report recommendations have been voluntarily completed or are well in progress.
- New content was added to the *Hydrogen Safety Best Practices Manual* for the following topics: hydrogen properties focusing on combustion and liquid hydrogen expansion; the indoor refueling of hydrogen fuel cell-powered forklifts; and chemical hydrogen storage. A new section, "So You Want to Know Something about Hydrogen," was created as a resource for students, technicians, and young engineers less familiar with hydrogen.
- The Hydrogen Incident Reporting and Lessons Learned Database added 56 new records from national laboratories, universities, and private-sector firms in the U.S. and other countries.

First Responders

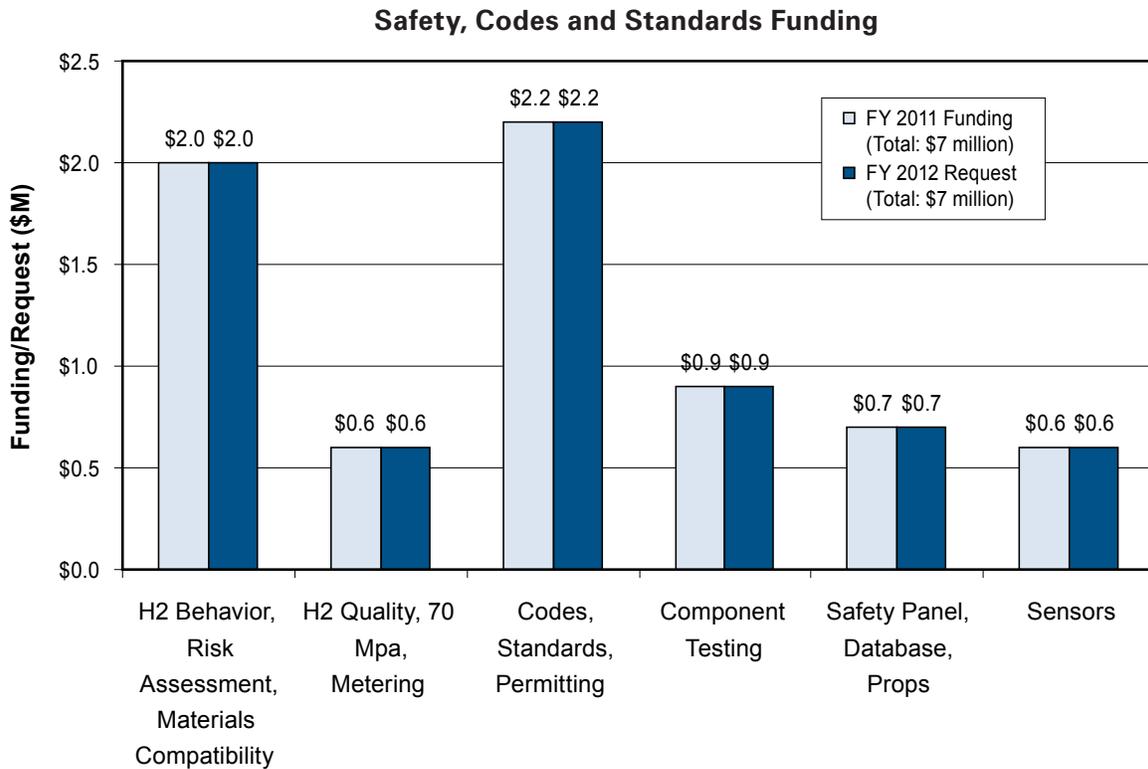

- The operations-level, prop-based course, Hydrogen Emergency Response Training for First Responders, was conducted at the Department of Defense's Defense Logistics Agency (DLA) near Tracy, California, where hydrogen fuel cell-powered forklifts are being used. Six one-day classes were conducted over a two-week period at the DLA's San Joaquin sites. To-date, approximately 350 first responders from 18 states have completed this course.

Education and Outreach

- Conducted Codes and Standards workshop in Anaheim, California, in collaboration with the Southern California Fire Protection Officers Association and the California Fuel Cell Partnership. Attendees included fire service members from at least seven key jurisdictions in the Los Angeles metropolitan area.

Budget

The sub-program received an appropriation of \$7.0 M in FY 2011. This allowed for sustained progress in key R&D and codes and standards development work. The President's FY 2012 budget request includes \$7.0 M for safety, codes and standards, which will ensure continuity in key R&D and focus areas as shown in the following figure.

FY 2012 Plans

The Safety, Codes & Standards sub-program will continue to work with codes and standards organizations to identify and address needs for the development of new hydrogen-specific codes and standards. To address these challenges, the sub-program will continue to support its rigorous technical R&D program.

In FY 2012 and beyond, the sub-program will continue to focus on critical safety R&D, such as assessment of materials compatibility for component designs, high-pressure tank cycle testing, and promoting a quantitative risk assessment approach to ensure the development of technically sound codes and standards. The sub-program will continue to promote the domestic and international harmonization of RCS by working with the appropriate domestic and international organizations such as NFPA, International Code Council, SAE International, CSA, and the ISO. The sub-program will continue to participate in the IPHE’s Regulations, Codes and Standards Working Group and the IEA’s Hydrogen Implementing Agreement, both of which have been engaged in hydrogen safety work.

E-mail: Antonio.Ruiz@ee.doe.gov

Start Date: Fiscal Year (FY) 2002

End Date: Project continuation and direction determined annually by DOE

FY 2011 Objectives

- (1) Scenario Analysis, Risk Assessments for Safety
 - Develop a scientific basis and the associated technical data for modifying or developing new codes and standards for the commercial use of hydrogen.
 - Develop benchmark experiments and a defensible analysis strategy for risk assessment of hydrogen systems.
 - Develop and apply risk-informed decision-making tools in the codes and standards development process.
- (2) Hazards Mitigation Technologies for Hydrogen Applications
 - Determine the effectiveness of ventilation, active sensing, and similar engineered safety features.
- (3) Codes and Standards Advocacy
 - Provide technical management and support for the Safety, Codes and Standards sub-program element.
 - Participate in the hydrogen codes and standards development/change process.

Technical Barriers

This project addresses technical barriers from the Codes and Standards section of the Fuel Cell Technologies 2007 Multi-Year Research Plan:

- (F) Limited DOE Role in the Development of International Standards

- (I) Conflicts Between Domestic and International Standards
- (N) Insufficient Technical Data to Revise Standards
- (P) Large Footprint Requirements for Hydrogen Fueling Stations
- (Q) Parking and Other Access Restrictions

Contribution to Achievement of DOE Codes and Standards Milestones

This project will contribute to achievement of the following DOE milestones from the Codes and Standards section of the Fuel Cell Technologies Program Multi-Year Research, Development and Demonstration Plan:

- **Milestone 21:** Completion of necessary codes and standards needed for the early commercialization and market entry of hydrogen energy technologies. (4Q, 2012)
- **Milestone 8:** Complete investigation of safe refueling protocols for high pressure systems. (1Q, 2012)
- **Milestone 9:** Complete risk mitigation analysis for advanced transportation infrastructure systems. (1Q, 2015)
- **Milestone 12:** Complete research needed to fill data gaps on hydrogen properties and behaviors. (2Q, 2010)

FY 2011 Accomplishments

- Improved hydrogen jet release and ignition understanding with high-fidelity data.
- Measured dispersion statistics and ignition probability boundaries for a high source pressure release with a choked exit flow and compared measurements to predicted values.
- Acquired and analyzed hydrogen release data into vehicle compartments in support of a new Global Technical Regulation in support of a performance-based test methodology for hydrogen powered vehicles.
- Key validation experiments of H₂ releases and delayed ignition deflagration have been performed for indoor hydrogen forklift trucks.
- A consequence model for indoor releases from hydrogen forklift trucks has been developed and validated with experimental data.
- The Sandia turbulent entrainment model for cold hydrogen jets has been validated against high-momentum jet data (from Forschungszentrum Karlsruhe tests) and used in a liquid hydrogen separation distance study for National Fire Protection Association (NFPA) 2.

Introduction

The purpose of this project is to enable risk-informed development of codes and standards for hydrogen fuel cell technology that is based on a traceable, scientific foundation. Our scenario analysis and risk assessment efforts focus on defining scenarios for the unintended release of hydrogen and quantifying the consequences through scientific experimentation and modeling. Quantitative risk assessment (QRA) is used to identify risk drivers and risk mitigation strategies for the commercial use of hydrogen. We combine our validated models with QRA to support risk-informed decision-making in the code development process.

Approach

We develop an understanding of combustion behavior and thermal effects from the unintended releases of hydrogen in the built environment. We consider ignition characteristics, partially confined spaces such as hydrogen forklift trucks in warehouses, and liquid hydrogen handling. Technical information is disseminated through a variety of public channels and is used by codes and standards developers writing for the International Code Council and NFPA. International partnerships for vetting technical data and analysis methods occur through activities such as International Energy Agency Task 31 on Hydrogen Safety. Efforts in FY 2011 have focused on developing the basis for regulations and codes and standards development in the area of hydrogen releases in enclosures, ignition mechanisms, and liquefied hydrogen release behavior.

Results

Fundamental Ignition Phenomena of Unintended Hydrogen Releases

Ignition boundaries for turbulent natural gas jets have previously been found to correlate well with the flammability factor (FF), or the integration of the probability density function (PDF) between the fuel flammability limits. Although the FF does not predict flame light-up probability, it nonetheless allows modelers to determine the likelihood that an ignition kernel will form within a jet region when an ignition source is present. To verify the FF concept applies to hydrogen releases, light-up boundary, ignition probability, and concentration statistics for turbulent hydrogen jets were quantified at Sandia during FY 2008 through a combination of laser spark ignition and planar laser Raleigh scatter (PLRS) imaging. These measurements were also performed for methane jets, and it was found that the methane jet maximum axial and radial extents of the light-up boundaries were roughly a third lower. It should be noted, however, that smaller jet exit diameters and Reynolds number used for the Sandia study may have impacted the light-up flow features. An additional discrepancy, however, was that the centerline measured FF did not agree well with the

measured laser spark ignition probability in the jet far field. Thus, it was concluded that the experimental methodology needed to be refined.

New ignition probability and jet light-up boundary measurements were performed in FY 2011 with the following experimental modifications: (1) the sample size was doubled; (2) a longer stabilization time was between sparks was used; (3) the number of thermocouples used to detect ignition was increased from 3 to 10; and (4) air conditioner vents and wind tunnel outlets were blocked to minimize air current disruptions. With these improvements, the new ignition probability measurements had much better agreement with the previously recorded methane and methane jet FF values, as can be seen in Figure 1. Nonetheless, methane and hydrogen light up boundaries, were essentially unchanged from the previous literature measurements; thus it was concluded the differences in flame light-up boundary were primarily driven by flow characteristics. Future measurements will quantify the jet flow features during ignition to support the engineering model development of sustained light-up phenomena.

Modeling of High Source Pressure Releases

Self-similar behavior for turbulent, subsonic heterogeneous jets exists for a broad range of gases, including hydrogen, which allows jet behavior to easily be modeled using canonical analytic expressions. However, for releases from storage pressures above the critical ratio (~ 1.9 for hydrogen), the exit flow chokes and underexpanded jets form, which are characterized by complex shock structure and nonuniform velocity distributions. A Mach disk at the end of the shock structure serves as the supersonic/subsonic boundary and is used as the effective source for the subsonic dispersion models; it

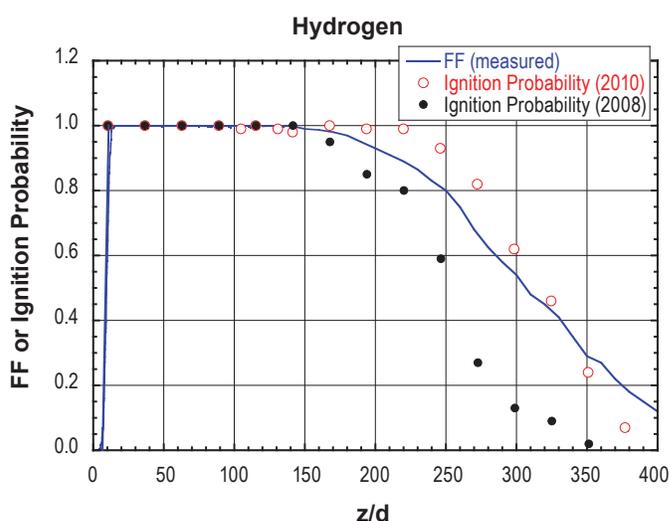

FIGURE 1. Original and Repeated Centerline Profile FF and Laser Spark Ignition Probability Measurements

is generally several factors wider than the jet exit diameter. Although source models that predict effective Mach disk diameter size and jet exit thermodynamic variables have been developed, limited validation data is available for choked hydrogen releases.

In FY 2011, the equation-of-state in these models was updated (Able-Noble) to better account for hydrogen compressibility. A new high-pressure stagnation chamber was integrated into Sandia's Turbulent Combustion Laboratory, and was used to acquire validation data from a choked hydrogen jet with a 10:1 pressure ratio and 1.5 mm nozzle diameter. The maximum measured centerline light-up distance was 367 mm downstream from the nozzle exit. Downstream concentration statistics were collected using PLRS imaging, while jet exit shock structure was imaged with schlieren photography. Measured (black) and modeled (red) FF contours from the concentration measurements are shown in Figure 2. Close agreement is achieved between the two methods, which indicate the self-similar jet behavior is preserved in the subsonic portion of the jet release. Computed effective source diameters, which are linearly proportional to ignitable boundary maximum extents, are tabulated for each model on the right. Although no model prediction was within 10% of the SNL experimental value, simpler models that neglect momentum and energy conservation performed the best while more complicated models that accounted for entropy change across the Mach disk performed the worst. More work is needed to determine why, but this is likely at least partially due to poorly predicted entrainment within the jet near field

around the Mach disk. These data will ultimately be used to extend and validate the predictive capabilities of the ignition and flame light-up models and will form an important QRA input that ultimately impacts codes and standards separation distance decisions in NFPA 2, NFPA 55, and International Energy Agency 19.

Performance-Based Hydrogen Leakage Testing in Passenger Vehicle Compartments

International regulatory representatives have proposed the performance-based test methodology for hydrogen fuel cell vehicle fuel system integrity certification in a new global technical regulation (GTR). For this testing methodology, automotive original equipment manufacturers (OEMs) self certify each vehicle. To ensure compliance, government regulators periodically inspect the system performance of randomly selected vehicles during barrier/rollover crash tests. Since a single failure for any safety criteria may result in a model line recall, OEMs are strongly incentivized to maintain vehicle safety compliance; however, OEMs have the flexibility to decide the design approach that best achieves the prescribed safety level. The GTR proposal specifies that the test is failed if within 1 hour post-crash, hydrogen leakage rates exceed 118 liters/min or flammable mixtures develop within the passenger cabin or trunk. An analysis of the capabilities necessary to detect the second failure mode was performed through exploratory in-vehicle leakage tests at SRI International's Corral Hollow Experimental Site. Hydrogen concentrations were primarily

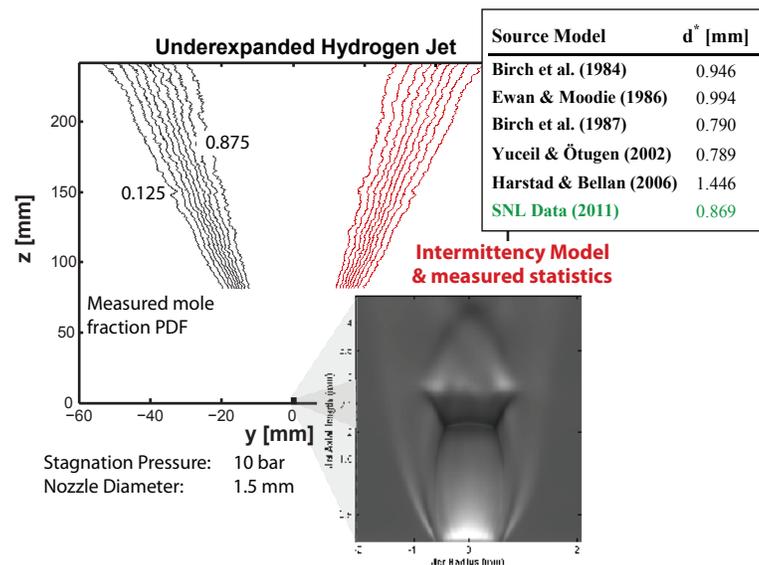

FIGURE 2. Flammability factor maps for the choked hydrogen jet ($p_0/p = 10$, $d = 1.5$ mm), with black contours generated from direct PDF integration, while red contours were generated from concentration statistics and an applied intermittency model. A schlieren image of jet exit shock structure is shown at the bottom, while tabulated predictions (black) and measurements (green) of the effective source diameter are shown to the right.

derived from oxygen depletion sensors, and were compared to directly measured concentrations from co-located hydrogen sensors (location details are shown in Figure 3a). Close agreement between the two sensor technologies was observed as shown in Figure 3b. Since oxygen depletion measurements have the additional advantage that nonflammable gases can be used, helium was investigated as a surrogate due to its similar diffusion and jet spreading characteristics. Good agreement in overall dispersion trends for both gases highlights the flexibility of the indirect sensor method. While hydrogen mixture fractions depended on release characteristics (e.g., rate, location, type), results of an analytic examination indicate that pinhole leaks from moderate source pressures likely would produce unacceptably high in-vehicle hydrogen concentrations. The optimum sensor location for leak detection was determined to be high above the release point. Accordingly, sensor placement for crash tests involving vehicle rollovers must account for the final vehicle orientation. Test results provided quantifiable support for the U.S. National Highway Traffic Safety Administration proposal for a multinational performance-based hydrogen leakage test standard at a GTR meeting held September 8, 2010 in San Francisco, CA.

Data shows a comparison of volumetric concentration measurements from co-located H₂ and O₂ sensors in the trunk and passenger cabin for the baseline condition.

Unintended Releases of Hydrogen in Partially Enclosed Spaces

Sandia has been working with OEMs to develop scientific understanding that will form the basis for risk-informed safety codes and standards for safe operation of indoor hydrogen fuel cell forklift vehicles. A combined modeling and experimental approach has been used to develop an experimentally validated model for dispersion and ignition of unintended releases from hydrogen forklift vehicles in warehouses. As part of this work the validated forklift warehouse release model has been used to study the effect of leak size, ignition delay time, ventilation, and warehouse volume on the associated consequences. Results of this modeling study are being used in a risk analysis to develop new risk-informed indoor refueling codes and standards.

The indoor hydrogen release experiments were designed based on OEM forklift specifications and leak size, and

the gaseous hydrogen indoor dispensing code in NFPA 2 and 52. The warehouse sizing, ventilation, and amount of vehicle onboard hydrogen were based on the parameters outlined in the NFPA codes. The experiments were performed in a subscale warehouse test facility (Figure 4) at the SRI Corral Hollow Experiment Site to provide data for model validation. The SRI subscale warehouse has a volume and height approximately 1/2.8 that of a full-scale 1,000 m³ warehouse with a 7.62 m ceiling. The release diameter for the experiments was designed so that the mass flowrate matched the scaled mass flow rate versus scaled tank blow-down curve for a full-scale forklift release. Measurements were made of the hydrogen concentration, flame speed, and ignition delay overpressure in the scaled warehouse. As part of the work a dispersion model and deflagration model of the subscale warehouse and forklift geometry were developed. These models were used prior to the tests to estimate the placement of concentration and pressure sensors in the subscale warehouse and to determine the amount of expected overpressure from ignition of the hydrogen release. Pretest ignition deflagration simulations of the test geometry indicated that the maximum ignition overpressure would be approximately 30 kPa (0.3 barg) if the warehouse was completely (100%) sealed and the effects of wall heat transfer were neglected. Based on these simulations a wooden pressure relief panel was designed and placed in the doorway of the steel front wall of the scaled warehouse prior to the beginning of the deflagration testing.

Figure 4 shows comparisons of the predicted ignition overpressure from the simulations with data from the experiment for a pressure sensor in the center of the warehouse side wall nearest the forklift. Results are shown for simulations with and without heat transfer to the walls and also for the cases where the warehouse is completely sealed (100%) or the measured leakage area (36.7 cm²) is incorporated into the model. The results with the measured air leakage rate and heat transfer to the walls are found to be in good agreement the experimental data. Figure 4 also shows that incorporating natural ventilation in the warehouse reduces the peak deflagration overpressure from approximately 25 kPa to 5 kPa.

The results of the modeling and experiments demonstrate that pressure relief panels or passive natural ventilation can be used as an effective means to mitigate deflagration overpressure arising from ignition of the released hydrogen. Simulation results also indicate that increasing the warehouse volume beyond the requirements currently specified also reduces the overpressure. Both simulations and experiments show that forced ventilation has little effect on the hydrogen concentration and deflagration overpressure in the early stages of the release.

Results of the modeling and experiments were presented to the DOE Technical Team, the Hydrogen Industrial Panel on Codes and Standards, and at the Annual Fuel Cell and Hydrogen Energy Conference. Based on feedback from these presentations a new indoor refueling task group was formed

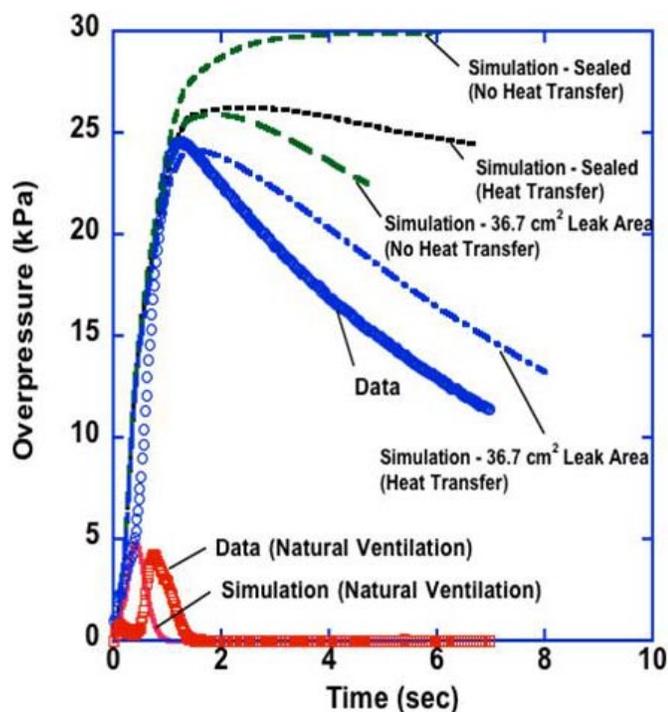

FIGURE 4. Comparison of Measured Ignition Overpressure in the SRI International Subscale Warehouse Facility with Results from FUEGO/FLACS Model Simulations

within NFPA 2 to utilize the experimental data and validated model in a science-based risk-informed process to develop new indoor refueling codes and standards for NFPA 2.

Conclusions and Future Directions

This project provides key understanding to enable the deployment of early market hydrogen systems. In FY 2011:

- We performed consequence analysis of indoor refueling and operation of hydrogen powered industrial trucks.

- Incorporated data from existing demonstration and projects into the QRA of hydrogen technologies.
- Improved the existing predictive model of ignition in turbulent flames to include sustained flame light-up probability.
- We improved the understanding of high-source pressure hydrogen releases in support of improved NFPA 2 separation distances from compressed gas applications.
- We developed an understanding of high-momentum low-temperature hydrogen plume behavior and supported NFPA 2 separation distance activities on liquid hydrogen.
- Performed risk analysis of advanced storage materials in support of NFPA 2 activities.

This project will continue to enable hydrogen and fuel cell technology deployment through developing the defensible technical basis for codes and standards. We will perform work to:

- Complete risk analysis of indoor refueling and work with codes and standards development organizations to provide technical data for science-based risk-informed indoor refueling codes and standards
- Perform study to identify potential mitigation features associated with hydrogen refueling stations and indoor refueling efforts.

Start Date: Fiscal Year (FY) 2002
End Date: Project continuation and direction determined annually by DOE

- (I) Conflicts Between Domestic and International Standards
- (N) Insufficient Technical Data to Revise Standards
- (P) Large Footprint Requirements for Hydrogen Fueling Stations
- (Q) Parking and Other Access Restrictions

Contribution to Achievement of DOE Codes and Standards Milestones

This project will contribute to achievement of the following DOE milestones from the Codes and Standards section of the Fuel Cell Technologies Program Multi-Year Research, Development and Demonstration Plan:

- **Milestone 21:** Completion of necessary codes and standards needed for the early commercialization and market entry of hydrogen energy technologies. (4Q, 2012)
- **Milestone 9:** Complete risk mitigation analysis for advanced transportation infrastructure systems. (1Q, 2015)

FY 2011 Objectives

- (1) Scenario Analysis, Risk Assessments for Safety
 - Develop a scientific basis and the associated technical data for modifying or developing new codes and standards for the commercial use of hydrogen.
 - Develop benchmark experiments and a defensible analysis strategy for risk assessment of hydrogen systems.
 - Develop and apply risk-informed decision-making tools in the codes and standards development process.
- (2) Hazards Mitigation Technologies for Hydrogen Applications
 - Determine the effectiveness of ventilation, active sensing, and similar engineered safety features.
- (3) Codes and Standards Advocacy
 - Provide technical management and support for the Safety, Codes and Standards sub-program element.
 - Participate in the hydrogen codes and standards development/change process.

Technical Barriers

This project addresses technical barriers from the Codes and Standards section of the Fuel Cell Technologies 2007 Multi-Year Research Plan:

- (F) Limited DOE Role in the Development of International Standards

FY 2011 Accomplishments

- Expanded use and acceptance of quantitative risk assessment (QRA) to establish risk-informed codes and standards requirements.
- Harmonization of National Fire Protection Association (NFPA) and International Organization for Standardization (ISO) use of risk in establishing gaseous hydrogen facility separation distances.
- Evaluation of risk-reduction potential of accident mitigation features.

Introduction

The purpose of this project is to enable risk-informed development of codes and standards for hydrogen fuel cell technology that is based on a traceable, scientific foundation. Our scenario analysis and risk assessment efforts focus on defining scenarios for the unintended release of hydrogen and quantifying the consequences through scientific experimentation and modeling. Quantitative risk assessment is used to identify risk drivers and risk mitigation strategies for the commercial use of hydrogen. We combine our validated models with QRA to support risk-informed decision-making in the code development process.

Approach

Risk-informed code development enables commercialization of and fuel cell and hydrogen technologies by identifying code requirements that will reduce the associated risk to socially acceptable levels. Our risk activities include QRAs of hydrogen facilities, development of risk management strategies, and global harmonization of performance-based standards. Efforts in FY 2011 have focused on (A) harmonization of the NFPA and ISO risk-informed approaches for establishing separation distances; and (B) risk prevention and mitigation feature analysis. The hazards involved with unintended releases of hydrogen may be mitigated through early detection technologies or suppressed through thermal management techniques and engineered responses. As a result of the analysis of accident prevention and mitigation features, we will be able to inform credit tables that will be assembled for separation distances and other requirements in hydrogen codes.

Results

Harmonization of NFPA and ISO Separation Distances

The development of a set of safety codes and standards for hydrogen facilities is necessary to ensure they are designed and operated safely. To help ensure that a hydrogen facility meets an acceptable level of risk, code and standard development organizations (SDOs) are utilizing risk-informed concepts in developing hydrogen codes and standards. Two SDOs, the NFPA and the ISO have been developing standards for gaseous hydrogen facilities that specify the facilities have certain safety features, use equipment made of material suitable for a hydrogen environment, and have specified separation distances. Under DOE funding, Sandia National Laboratories (SNL) has been supporting efforts by both of these SDOs to develop the separation distances included in their perspective standards. Important goals in these efforts are to use a defensible, science-based approach to establish these requirements and to the extent possible, harmonize the requirements. International harmonization of regulations, codes and standards is critical for enabling global market penetration of hydrogen and fuel cell technologies.

Efforts to harmonize the ISO and NFPA approaches for establishing separation distances have generally been successful as both used essentially the same risk approach for evaluating separation distances developed by SNL [1]. Similarly, the SNL consequence models and the hydrogen leak data generated by SNL [1] have also been generally adopted for use in the ISO separation distance evaluation. However, there are some important differences in the ISO and NFPA analyzes that make it difficult to compare the resulting separation distances. These differences include the scope of the application (i.e., bulk storage versus fueling station), the differences in the separation distance table

format used in the specific standards (pressure ranges and exposures), the risk criteria used in the risk analysis, the utilization of component leak data in the risk assessment, and the importance placed on the risk results. Additional efforts occurred this year to understand the impact of differences in the data used in the two analyses and the effect on the resulting separation distances.

A major difference between the NFPA and ISO analyses was due to the component leak frequencies used in the analysis. The difference in the leak frequencies is related to the binning of the data used by SNL for generating hydrogen-specific leak frequency estimates using Bayesian analysis. A cursory analysis of the generic data by the ISO TC 197 [2] separation distance task leader was utilized in a non-rigorous statistical approach to generate the leak frequencies used in the ISO QRA. The ISO data analysis only utilized a subset of the available generic data, did not include any hydrogen-specific data, and did not evaluate the leak frequencies using a justifiable statistical approach. Instead, the limited review of the generic data was utilized to generate arbitrary, idealized linear (on a log-log plot) versions of leak frequency distributions generated by SNL. More importantly, the ISO leak frequencies were essentially shifted an order of magnitude based on the argument that some of the generic data was mis-binned and that a different binning scheme should be utilized.

In an effort to more rigorously evaluate the impact of the data binning performed by ISO and the resulting leak frequencies, SNL performed sensitivity studies in which both the generic and hydrogen specific data were rebinned, where appropriate, into the binning categories utilized in the ISO QRA. The rebinned data was then utilized in a Bayesian analysis to generate estimates of hydrogen component leak frequencies. The results for valves are highlighted in Figure 1.

A review of the generic leak frequencies for valves indicated that some of the data had been conservatively binned in the initial Bayesian analysis performed by SNL. The actual leak size represented in this data is uncertain. However, some of the data was rebinned into lower leak sizes, especially the data points identified by the ISO working group. In particular, many of the data points initially binned as ruptures (30% to 100% leaks) were rebinned into smaller leak categories. However, several data points remained as 100% leaks. A Bayesian analysis was performed using this revised data. As illustrated in Figure 1, the resulting hydrogen mean leak frequency curve has lower frequencies than those reported in Reference 1. However, the frequencies are not substantially less (less than a factor of 2 different) which does not justify, for example, using the 100% leak size frequency as representative of leaks in the 10% to 100% range (this is a non-conservative value for that range of leaks). In contrast, it would be conservative to utilize the leak frequency for 10% leaks to represent the leaks in that range. A more realistic result would occur if the original leak size bins from reference [1] were utilized

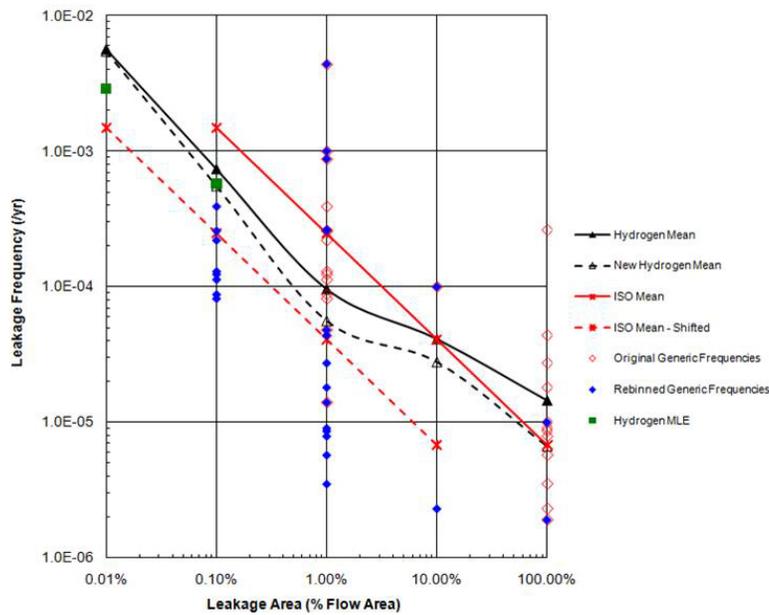

FIGURE 1. Results of Bayesian Analysis with Valve Data Rebinning

(i.e., leaks between 30% to 100% of the flow area are better represented by the leak frequency estimate for a 100% leak).

The results of the rebinning of data and Bayesian analysis for compressors resulted in similar results as for valves. The effect of the rebinning of the data for joints and hoses was negligible. Based on this more rigorous evaluation, the rebinning of selected generic data performed by the ISO working group does not provide an adequate basis for shifting the SNL-generated hydrogen leak frequencies reported in reference [1].

The ignition probabilities used in the QRA were also different in the NFPA and ISO QRAs. The NFPA QRA utilized ignition probabilities that changed with leak size and whether the ignition occurred immediately or was delayed. The NFPA ignition probabilities are provided in Table 1. The ISO risk model included a single ignition probability of 0.04 that was independent of leak size or ignition time. Although the selected ISO ignition probability was conservative over a range of leak sizes, as indicated below, its use skews the actual risk profile and the resulting selection of the separation distances.

TABLE 1. Hydrogen Ignition Probabilities used in NFPA QRA

Hydrogen Release Rate (kg/s)	Immediate Ignition Probability	Delayed Ignition Probability
<0.125	0.008	0.004
0.125–6.25	0.053	0.027
>6.25	0.23	0.12

To examine the significance of these differences in data, the impact of using the same component leak frequencies

and hydrogen ignition probabilities used in the NFPA QRA on the ISO risk results and associated separation distances was evaluated. The results are shown in Figure 2 for four ISO-specified systems that have varying number of components most susceptible to developing leaks. As indicated in Figure 2, the resulting risk profiles are very different than from the ISO QRA and result in generally higher risk estimates for a person standing at a specified distance. Although the risk is higher for most of the systems/modules, the risk is acceptable over a range of separation distances. For example, the highest risk level is associated with the complex gas system (C). Using the ISO risk criteria of 1E-5/yr and 4E-6/yr, the associated separation distances are approximately 5 m and 9 m, respectively. The risk estimate for both of these distances using the NFPA data is 2E-5/yr. However, for the very simple gas system (VS), the ISO risk estimate is nearly identical to that predicted using the NFPA data.

Accident Prevention and Mitigation Feature Evaluation

A concept being pursued in the NFPA hydrogen standard development is to take credit for prevention and mitigation features as a means to reduce separation distances. The reduction in the separation distance could be expressed as a reduction factor that represents the ratio of the separation distance without any mitigation feature to the separation distance with a mitigation feature credited. QRA has been performed, using the hydrogen

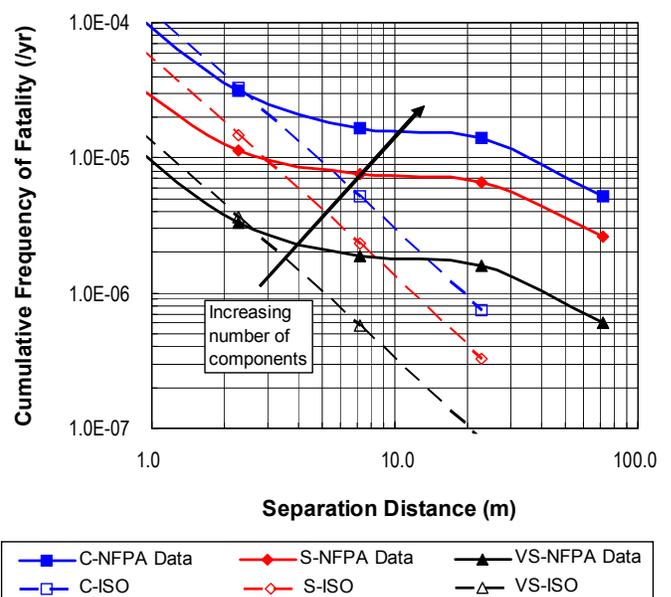

FIGURE 2. Results of Requantification of ISO QRA using NFPA Leak Frequency and Ignition Probabilities

system configurations and associated risk model used to establish the NFPA separation distances, for the following mitigation features taken individually (the risk reduction of combinations of these features has currently not been performed):

- Automatic leak detection and isolation
- Use of flow limiting orifices
- Use of barriers
- Reduction in number of components

The risk reduction potential and impact on separation distances associated with barriers was reported in 2010. The risk reduction potential of the other features was evaluated using the hydrogen system configurations and associated risk model used to establish the NFPA separation distances [1]. Preliminary results are summarized in the following.

Three different forms of detection and isolation are considered possible in a hydrogen bulk storage system:

- External flame and/or hydrogen detectors which can actuate one or more isolation valves.
- Internal process measurement (e.g., high flow or low pressure) that actuate one or more isolation valves.
- Excess flow valve that closes when flow exceeds a set amount.

These three different forms of detection and isolation may not be viable in specific hydrogen system applications. Furthermore, the set point for detection may be variable for each method. Rather than evaluate each method specifically, a generic risk assessment was performed where it is assumed that each detection system would detect leaks equal to or greater than 1% of the flow area in the largest pipe connected to the bulk storage system and isolate a portion of the bulk storage system. The probability of successful detection and isolation is assumed to be 0.9. Sensitivity calculations were performed for the case where the detection systems are only capable of measuring leaks equal to or greater than 10% of the flow area. Sensitivity calculation for the detection/system reliability was not performed as a 0.9 reliability appears to be sufficient to reduce the risk from hydrogen leaks.

The risk reduction potential for a detection/isolation system is dependent upon the location of the isolation valve. The closer the isolation valve is to the bulk storage system the better is the risk reduction potential. Figure 3 shows the results with isolation at the three different locations in a bulk storage system operating at 20.7 MPa. The reduction in separation distances range from a factor of 2 (7 m, corresponds to 0.75% leak) for isolation at the stanchion outlet to 2.8 (5 m, corresponds to 0.38% leak) for isolation at the tube trailer manifold, to 7 (2 m, corresponds to 0.06% leak) if isolation is on the tube trailer cylinders. Note that a large risk reduction is possible if the isolation valve can be placed on each tube trailer cylinder since this location would mitigate almost all leaks in the system. Reducing the

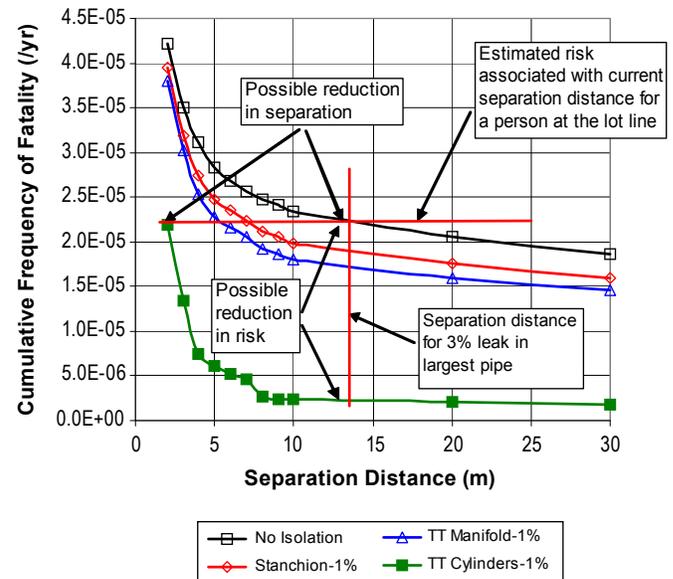

FIGURE 3. 20.7 MPa System Risk Results, Isolation at Different Locations (leaks equal to or greater than 1% of the flow area detected)

detection capability such that only leaks equal to or greater than 10% of the system flow area results in smaller risk and separation distance reductions.

Flow limiting orifices can also be used to limit the size of a leak and thus reduce the required separation distance. Similar to isolation systems, the location of the flow limiting orifice is important with regard to reducing risk and separation distances. For example, a flow orifice located in the tube trailer manifold in the 20.7 MPa bulk storage system modeled in the NFPA QRA would limit the flow rate from all leaks occurring downstream of the orifice. Using a flow orifice that is equivalent to 1% of the flow area would reduce the separation distance from 14 m (no orifice) to 6 m (a reduction factor of 2.33) if the same fatality risk is maintained. If the flow restriction can only be limited to 10% of the flow area, the separation distance reduces to 9 m (a reduction factor of 1.56). Locating a flow orifice at locations downstream of the tube trailer manifold would result in lower separation distance reduction factors.

The dominant risk contributors that were identified in the NFPA QRA [1] include leakage from valves, joints, and compressors. Limiting the number of these components in a hydrogen system would reduce the potential for hydrogen leakage and thus reduce the associated risk. To illustrate how this might impact risk and separation distances, 110 MPa systems with different number of risk-significant components was evaluated. All the system components were assumed to be at the same pressure and have an internal diameter of 8 mm. The results are shown in Figure 4 when a risk guideline of $2E-5$ /yr is used to select separation distances.

- (K) Lack of Sustained Domestic Industry Support at International Technical Committees
- (N) Insufficient Technical Data to Revise Standards

Contribution to Achievement of DOE Safety, Codes & Standards Milestones

This project contributes to achievement of the following DOE milestones from the Hydrogen Codes and Standards section of the Fuel Cell Technologies Program's Multi-Year Research, Development and Demonstration Plan:

- **Milestone 21:** Completion of necessary codes and standards needed for the early commercialization and market entry of hydrogen energy technologies. (4Q, 2012)

Fiscal Year (FY) 2011 Objectives

- Support development of new codes and standards required for commercialization of hydrogen technologies.
- Create code language that is based on the latest scientific knowledge by providing analytical, technical and contractual support.
- Participate directly on codes and standards committees to identify technology gaps, then work to define research and development needs required to close those gaps.
- Conduct laboratory testing to provide a basis for improved code language.
- Collaborate with industry, university and government researchers to develop improved analytical and experimental capabilities.

Technical Barriers

This project addresses the following technical barriers from the Hydrogen Codes and Standards section (3.7.4) of the Fuel Cell Technologies Program's Multi-Year Research, Development and Demonstration Plan:

- (A) Limited Government Influence on Model Codes
- (B) Competition among SDOs and CDOs
- (C) Limited State Funds for New Codes
- (F) Limited DOE Role in the Development of International Standards
- (G) Inadequate Representation at International Forums
- (H) International Competitiveness

FY 2011 Accomplishments

- Completed sensor test laboratory objective, round I and II of the NREL/Joint Research Centre (JRC) round robin inter-laboratory comparison, completed under a formal Memorandum of Understanding with the JRC laboratory (a European Commission funded laboratory). Round robin test result comparison provided validation of test methods.
- Hydrogen safety sensor market characterization composite data study is approximately 50% complete.
- Collaborative partnerships were established to develop four new hydrogen safety sensor technologies. These technologies are being developed by both public and private organizations. Testing of each of these sensor technologies was completed as part of NREL's sensor evaluation process.
- NREL/DOE field deployment study was completed in support of hydrogen safety sensor installation in an NREL facility. This study included testing sensors being evaluated by NREL's Environmental Health and Safety organization. NREL hosted a hydrogen safety sensor workshop, June 2011 to bring together key industry representatives. Results included defining gaps and setting research and development needs for sensor commercialization.
- Conducted hydrogen pressure relief device (HPRD) contract testing in support of HPRD1 component standards development. Test results were used to modify test protocols defined in the draft standard.

Introduction

Development of codes and standards has been identified in the DOE multi-year program plan as a key area needing support for the commercialization and growth of hydrogen technologies. NREL is providing research and development (R&D) support to these codes and standards organizations through validation testing, analytical modeling, and product commercialization efforts. NREL has been tasked with these responsibilities as defined in the DOE multi-year program plan.

Approach

NREL is participating on relevant codes and standards committees to help identify gaps and define R&D needs to close those gaps. Working at the committee level allows us to quickly identify areas that need R&D support and to work directly with the technical experts in planning a path forward. This process is instrumental in avoiding delays and setbacks in the development of new codes and standards and in the revision of existing codes and standards. By providing support from a national lab we are able to help establish codes and standards language with solid technical basis.

Hydrogen safety sensors are a key component for the safe commercialization of hydrogen technologies. NREL is tasked with being a national resource for testing sensors designed to meet the needs of this growing market. By developing standard test methods and measuring sensor performance of a wide range of sensors of different designs and from a many different manufacturers, NREL is characterizing sensor performance and identifying gaps relative to DOE performance targets. With this information we work closely with sensor manufacturers so that they can better understand the performance of their sensor relative to the needs of hydrogen stationary applications. This work is directed toward sensor R&D, such that sensor manufacturers, utilizing the resources of a national lab, can expedite their product development life cycle. In addition, the sensor market expertise gained by NREL will be used to support commercialization through development of representative codes and standards for safety sensor certification. Commercialization support includes collaboration with key stakeholders as well as direct participation on the relevant codes and standards committees.

Results

NREL has been working toward identifying gaps and supporting R&D efforts for developing new and improved hydrogen codes and standards. Results reported here are for efforts specifically directed at component level standards. Results are organized in the following three sections; Hydrogen Safety Sensors, Canadian Standards Association (CSA) HPRD1 and Codes and Standards Support.

Hydrogen Safety Sensors

DOE published performance targets for hydrogen safety sensors in the multi-year program plan. NREL has tested more than 40 commercially available sensors and near-term developmental sensors from six sensor categories. This test data is being compiled in a generic format as a resource for end users. This format will allow for publishing a characterization study of the sensor market, while keeping individual results proprietary. NREL is approximately 50% complete with compilation of this composite data product.

NREL completed validation testing of the sensor test apparatus that was built in FY 2010. Validation testing consisted of systems level testing to characterize the repeatability and reproducibility of the apparatus, showing capabilities surpassing requirements in certification standards. Capabilities were further validated through round robin testing completed with the JRC Institute for Energy laboratory in Petten, Netherlands.

NREL is currently working directly with more than 20 sensor developers to support commercialization as their products move from prototype designs to full-scale production. This effort is directed at providing independent evaluation and testing of sensor platforms. This work has been completed in conjunction with other DOE supported projects in developing new technologies that have shown promise in meeting the identified DOE sensor targets.

CSA HPRD1

Pressure relief devices have been identified as a key safety component on hydrogen storage systems. Inadvertent opening can result in a failure mode where there is a release of the entire contents of the storage vessel. CSA component standard HPRD1 is in draft format. This standard defines performance-based certification tests designed to show end-of-life reliability. NREL and CSA worked together to define validation testing required for hydrogen service suitability testing as part of the CSA HPRD1 draft standard. Defined testing includes pneumatic cycle testing in hydrogen on three valves of three different designs, three surrogate designs and post-test metallurgical examination. Test results identified leakage issues at -40°C low temperature test conditions. Further evaluation of the test methods identified thermal transients that were more severe than the valves would see in actual low temperature service. This information was reviewed by the HPRD1 technical committee, concluding that a revised set of test conditions are required to more accurately depict worst case low temperature operation. Revised test definitions now include low temperature soak conditions. Testing was repeated successfully validating the revised test procedures. HPRD validation testing has been completed based on a revised test scope to both validate the revised test protocol and to stay within the budgetary limits first determined within this subcontract test program. A final report is being written for completion within FY 2011.

Codes and Standards Support

Through direct participation on the hydrogen components codes and standards committees, NREL has identified R&D gaps, including further HPRD testing, localized fire testing, tank level stress rupture testing and radio-frequency identification fill protocol validation. NREL has developed statements of work required to close these gaps and finalize these components requirements.

Conclusions and Future Direction

NREL made significant contributions in supporting commercialization of hydrogen sensor technologies. This includes collaborative work with domestic and international partners. NREL hosted a hydrogen sensor workshop in June 2011 to identify R&D gaps to help define future sensor test laboratory direction. We completed validation testing in support of HPRD1 component standards and continue to work closely with codes and standards development organizations to close gaps and promulgate codes and standards that are based on the latest technical knowledge.

In addition to continuing to support component level codes and standards development, NREL will undertake a number of initiatives including:

- Identifying gaps to hydrogen technology commercialization.
- Providing national laboratory support needed to provide a sound basis for component level codes and standards content.
- Working directly with sensor manufacturers in order to reach performance targets defined in the DOE multi-year program plan.
- Executing sensor laboratory testing over a wider range of environmental conditions and finalizing long-term exposure and response time testing methodologies.
- Leveraging our efforts with national and international collaborations to provide a path toward commercialization of hydrogen components that are designed to meet the latest safety standards.

Start Date: Fiscal Year (FY) 2003
End Date: Project continuation and direction
determined annually by DOE

FY 2011 Objectives

- (1) Populate Technical Reference on Hydrogen Compatibility of Materials
 - Summarize data from published technical documents in a Web-based resource.
 - Update published Technical Reference chapters to reflect new data from Sandia materials testing activities.
- (2) Develop and Validate Materials and Components Test Methods
 - Enable technology deployment by generating critical material-property data for structural materials in hydrogen gas, emphasizing commercial materials tested in high-pressure hydrogen.
 - Optimize efficiency and reliability of standardized test procedures for generating design data for structural materials in high-pressure hydrogen gas.
- (4) Provide Science-Basis for Codes and Standards Development
 - Perform testing and analysis to provide the technical basis for codes and standards.
 - Provide leadership in the hydrogen codes and standards development/change process.

Technical Barriers

This project addresses technical barriers from the Hydrogen Codes and Standards section of the Fuel Cell Technologies 2007 Multi-Year Research Plan:

- (F) Limited DOE Role in the Development of International Standards

- (I) Conflicts between Domestic and International Standards
- (N) Insufficient Technical Data to Revise Standards

Contribution to Achievement of DOE Codes and Standards Milestones

This project will contribute to achievement of the following DOE milestones from the Codes and Standards section of the Fuel Cell Technologies Program Multi-Year Research, Development and Demonstration Plan:

- **Milestone 21:** Completion of necessary codes and standards needed for the early commercialization and market entry of hydrogen energy technologies (4Q, 2012). This project enables the development and implementation of codes and standards by providing expertise and data on hydrogen compatibility of structural materials.
- **Milestone 25:** Draft regulation for comprehensive hydrogen fuel cell vehicle requirements as a GTR approved (UN Global Technical Regulation). (4Q, 2010)

FY 2011 Accomplishments

- Organized and convened Hydrogen Compatible Materials Workshop in November, 2010.
- Exercised leadership roles in developing standards (Society of Automotive Engineers [SAE] J2579 and Canadian Standards Association [CSA] Compressed Hydrogen Materials Compatibility [CHMC]1) for qualifying hydrogen compatibility of materials and components.
- Conducted materials testing designed to improve fatigue life methods in SAE J2579 and CSA CHMC1 standards.

Introduction

A major barrier to the deployment of hydrogen technologies is the lack of validated safety codes and standards. The purpose of this project is to provide the technical basis for assessing the safety of hydrogen-based systems with the accumulation of knowledge feeding into the development or modification of relevant codes and standards. The materials compatibility effort focuses on developing optimized materials qualification methodologies and assembling a resource entitled the Technical Reference on Hydrogen Compatibility of Materials. This effort is driven by the need for a materials guide, as identified in the Multi-Year Research, Development and Demonstration Plan (Table 3.7.5). The content of the Technical Reference

is assembled through the process of vetting, consolidating, and documenting materials data from journal articles and institutional reports. Gaps in the database content uncovered during the process of composing the Technical Reference are addressed through a materials testing activity. Results from this materials testing illuminate the pathways to optimize materials qualification methods, enabling efficient, high quality testing to support rapid technology deployment.

Approach

The focus of the Hydrogen Materials and Components Compatibility project is to optimize materials characterization methodologies, generate critical hydrogen compatibility data for materials to enable technology deployment, and compose the Technical Reference on Hydrogen Compatibility of Materials. Two activities proceed in parallel: generating new data and understanding through materials testing, and identifying and summarizing existing data from technical documents. The high-priority structural materials featured in these activities are low-alloy and carbon steels, austenitic stainless steels, and aluminum alloys. The materials testing activity emphasizes high hydrogen gas pressures (>100 MPa), fatigue crack initiation and propagation test methods, and technology-critical material fabrication (e.g. welds) and service variables (e.g., temperature). The data from materials testing are rigorously reviewed to identify pathways to improve the test methods and to ensure the data are suitable for implementation in structural design.

As part of codes and standards advocacy, Sandia personnel provide leadership in the codes and standards development process through direct participation in organizations such as the American Society of Mechanical Engineers, CSA, and SAE. This participation ensures that the standards development organizations have the most current technical information on structural materials compatibility. Sandia personnel provide leadership in the development of both component design standards as well as materials testing standards.

Results

Sandia led a Hydrogen Compatible Materials Workshop on November 3, 2010. The goal of the workshop was to coordinate and plan international research and development (R&D) to harmonize characterization and design methodologies for hydrogen-compatible materials and components. The output from the workshop was a summary document that would guide international R&D and code development road mapping. The workshop format consisted of several overview presentations followed by a working meeting involving 35 leading experts from research labs, government, industry, and standards development organizations. The presentations were designed to provide the context for identifying gaps in technology research and

development as well as standards development for structural materials in hydrogen containment.

In the documented results of the workshop, several high-priority gaps were identified in the areas of technology development, code development, and research. For example:

- High-strength, low-cost materials for long-life hydrogen service.
- Measurements of mechanical properties of structural metals in high-pressure hydrogen gas, in particular fatigue properties.
- Influence of welds on hydrogen compatibility of structures.
- Publicly available database for properties of structural materials in hydrogen gas.

The Sandia team has leadership roles in developing sections of the SAE J2579 (“Technical Information Report for Fuel Systems in Fuel Cell and Other Hydrogen Vehicles”) and the CSA CHMC1 standards that are pertinent to qualifying structural metals for hydrogen containment. Currently, the potential for hydrogen effects on fatigue cracking of structural metals is not adequately addressed in the SAE J2579. The containment vessel is qualified for severe pressure-cycle service using hydraulic testing only. Sandia has provided the technical basis for the following safety qualification philosophy applied to the containment vessel:

- Certain structural metals exhibit minimal effects of hydrogen on fracture properties. For these structural metals, hydraulic testing is sufficient for qualifying the containment vessel for severe pressure cycling. Currently, two structural metals are in this category: 6061 aluminum and 316 stainless steel with greater than 12% nickel. Other structural metals can be included in this category provided the materials are subjected to four tests and meet the specified acceptance criterion for each test. The four tests (described in a new Appendix C.15) are the slow strain rate tensile test, two fatigue life tests, and the fatigue crack growth test, in which each test is conducted in hydrogen gas.
- Structural metals that do not meet the materials testing acceptance criteria in Appendix C.15 can still be selected for containment vessel components. In this case, the containment vessel must be subjected to both the hydraulic pressure cycling test and an additional severe pressure cycling test using hydrogen gas. The protocol for conducting this durability performance test using hydrogen gas has been included in the new Appendix C.14.

The SAE J2579 effort has involved coordination with international experts from the U.S., Japanese, and European automakers. The sections on qualifying structural metals for hydrogen containment are expected to also form the

foundation for addressing hydrogen compatibility of metal components in the Global Technical Regulation (GTR).

The Sandia team has a leadership role in the new CSA Technical Advisory Group (TAG) for the CHMC1 standard. The content of this standard focuses on reliable test methods for structural materials in hydrogen gas. This standard was motivated by the lack of specific methods for qualifying structural metals for hydrogen service in component standards, such as the CSA standards for fuel cell vehicle components. Component standards that do not contain specific guidance for qualifying structural metals in hydrogen service can reference the CHMC1 standard. The CHMC1 document is scheduled for review by CSA in August 2011.

The fatigue life materials test is considered to be particularly relevant for many hydrogen containment components on fuel cell vehicles. For example, this test has been included in both the CSA CHMC1 and SAE J2579 standards. Fatigue life tests that employ smooth or notched specimens are intended to evaluate the effect of hydrogen on fatigue crack initiation. The output from fatigue life testing is an “S-N curve” for the material, which is a locus of points representing the number of cycles to failure (N) for a constant stress amplitude (S) applied to the test specimen. One of the principal objectives of the fatigue life testing in this Materials Compatibility task is to evaluate whether fatigue crack initiation dominates the number of cycles to failure. For this objective, it must be recognized that the number of cycles to failure (N) consists of the number of cycles for crack initiation (N_i) plus the number of cycles for crack propagation (N_p). Since tests on smooth or notched specimens are intended to evaluate the effect of hydrogen on crack initiation, the ratio of N_i/N should be nearly equal to 1. The first series of tests in this task were intended to establish the N_i/N ratio for a notched specimen geometry that is proposed for the CSA CHMC1 and SAE J2579 standards.

The S-N curve was measured for cylindrical, circumferentially notched specimens fabricated from the austenitic stainless steel 21Cr-6Ni-9Mn (21-6-9). Specimens from hydrogen-charged (200 wppm H) and non-charged 21-6-9 were tested at constant stress amplitudes, and the number of cycles to failure, N, were recorded for each test. The tests were conducted at a load ratio, R (ratio of minimum stress to maximum stress), equal to 0.1 and a load-cycle frequency of 1 Hz. In addition, each specimen was instrumented with an extensometer and the direct-current potential difference system to detect crack initiation. Results showing the number of cycles for crack initiation, N_i , and the number of cycles to failure, N, for both hydrogen-charged and non-charged specimens are summarized in Figure 1.

Two results are notable in Figure 1. First, hydrogen does not have a significant effect on the fatigue life of the 21-6-9 stainless steel. Second, the number of cycles for crack initiation, N_i , is approximately 50% of the total number of cycles to failure. The second observation

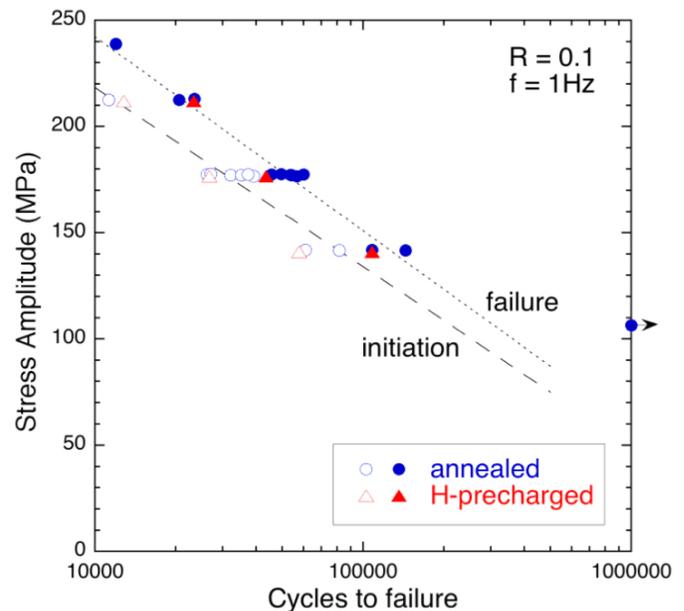

FIGURE 1. Stress amplitude (S) vs. number of cycles for crack initiation (N_i) and total number of cycles to failure (N) for hydrogen-charged and non-charged 21-6-9 stainless steel.

indicates that the number of cycles to failure measured from the circumferentially notched specimen does not adequately approximate the number of cycles for crack initiation. This insight may influence the specimen geometry that is specified in the CSA CHMC1 and SAE J2579 standards.

Hydrogen containment component stakeholders have expressed interest in aluminum alloys due to their compatibility with hydrogen gas and low cost relative to stainless steels. Consequently, Sandia has included modern, high-performance aluminum alloys in its materials testing activity. Although aluminum alloys are generally considered to be resistant to hydrogen-assisted fracture in dry hydrogen gas, some questions remain about applying reliable test methods. Sandia has conducted some preliminary fatigue crack growth testing on 7475-T7351 aluminum in 103 MPa hydrogen gas. Testing duration was greater than 60 hours, and the cyclic plastic deformation associated with fatigue testing was intended to promote the exposure of “fresh” (non-oxidized) metal surface to hydrogen gas. However, even in this testing condition, the results in Figure 2 show essentially no difference between the test in hydrogen gas and a test performed in laboratory air. These initial results support the notion that aluminum alloys have superior hydrogen compatibility among common structural metals.

Conclusions and Future Directions

In FY 2011:

- Hydrogen Compatible Materials Workshop identified important technology gaps:

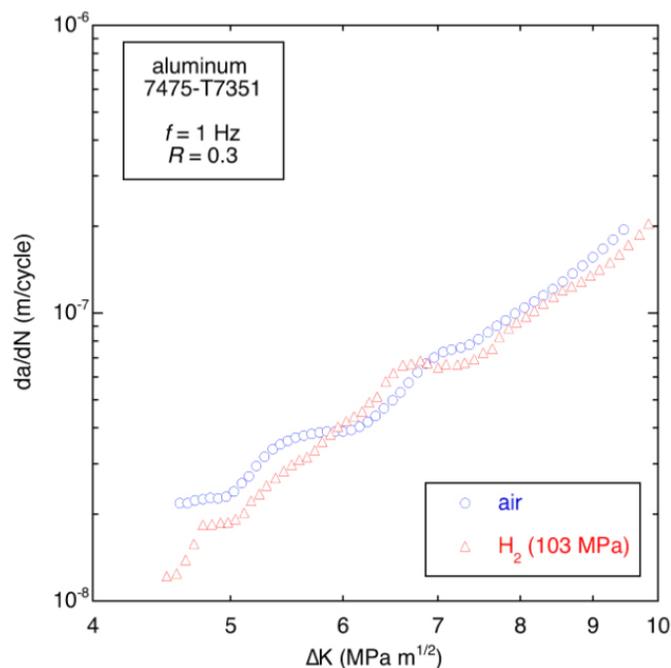

FIGURE 2. Fatigue crack growth rate (da/dN) vs. stress-intensity factor range (ΔK) relationships for 7475-T7351 aluminum in 103 MPa hydrogen gas and air.

- Workshop output guides R&D prioritization.
- Methods developed for qualifying hydrogen compatibility of materials and components in two standards: SAE J2579 and CSA CHMC1.
- Materials testing motivated by standards development:
 - Improving fatigue life testing methods impacts SAE J2579 and CSA CHMC1.

Future Work:

- Establish optimum methods for measuring fatigue properties of steels in high-pressure hydrogen for inclusion in standards.
- Measure hydrogen-affected properties of representative stainless steel welds in gas distribution manifolds.
- Complete first draft of CSA CHMC1 standard.
- Procure pressure vessel with variable-temperature feature for new fatigue testing capability.

Start Date: Fiscal Year (FY) 2010

End Date: Project continuation determined
annually by DOE

FY 2011 Objectives

- (1) Provide technical basis for the development of standards defining the use of steel (type 1) storage pressure vessels for gaseous hydrogen:
 - Compare fracture mechanics based design approach for fatigue assessment of pressure vessels for gaseous hydrogen to full-scale performance tests.
 - Generate performance test methods and data for fatigue assessment of full-scale pressure vessels with gaseous hydrogen.
- (2) Codes and standards advocacy:
 - Participate in the standards development activities for gaseous hydrogen storage in pressure vessels, in particular Canadian Standards Association (CSA) and Society of Automotive Engineers (SAE) activities.

Technical Barriers

This project addresses technical barriers from the Codes and Standards section of the Fuel Cell Technologies 2007 Multi-Year Research Plan:

- (F) Limited DOE Role in the Development of International Standards
- (I) Conflicts between Domestic and International Standards
- (N) Insufficient Technical Data to Revise Standards

Contribution to Achievement of DOE Codes and Standards Milestones

This project will contribute to achievement of the following DOE milestones from the Codes and Standards

section of the Fuel Cell Technologies Program Multi-Year Research, Development and Demonstration Plan:

- **Milestone 21:** Completion of necessary codes and standards needed for the early commercialization and market entry of hydrogen energy technologies (4Q, 2012). This project enables the development and implementation of codes and standards by providing expertise and data on hydrogen compatibility of hydrogen pressure vessels.
- **Milestone 25:** Draft regulation for comprehensive hydrogen fuel cell vehicle requirements as a GTR approved (UN Global Technical Regulation). (4Q, 2010)

FY 2011 Accomplishments

- Built infrastructure for accelerated pressure cycling of hydrogen storage tanks.
- Fatigue crack growth testing of low-alloy steels extracted for pressure vessels shows engineering predictions to be conservative relative to performance testing of pressure vessels.
- Pressure cycling of two pressure vessel designs (T1 and T2 respectively):
 - T1 design: >47,000 cycles (and continuing three tanks as of July 2011).
 - T2 design: >26,000 cycles (and continuing one tank as of July 2011).
- Pressure cycling pressure vessels with engineered defects to quantify effects of existing flaws:
 - Four failures observed (stable through-wall cracks).
 - Greater number of cycles to failure than predictions.
- Procedures for pressure testing with gaseous hydrogen are being included in CSA Hydrogen Powered Industrial Truck (HPIT)1 and SAE J2579 working documents for performance testing.

Introduction

Fatigue cracks can nucleate and grow in metals subjected to cyclic stress. The increment of crack growth per load cycle (da/dN) is a function of the driving force for fatigue cracking, which is called the applied stress intensity factor range (ΔK). Under conditions of stable fatigue crack growth, a simple empirical relationship can be used to describe fatigue crack growth in terms of the driving force: $da/dN = C(\Delta K)^m$, where C and m are experimentally determined constants.

Fatigue crack growth of a pressure vessel subjected to pressure cycling is enabled by the presence of manufacturing defects in the steel and accelerated by exposure to gaseous hydrogen. The latter characteristic is often referred to as “hydrogen embrittlement” and depends on the partial pressure of the gaseous hydrogen and the kinetics of hydrogen uptake into the steel. Consequently, the fatigue crack growth relationship is affected by variables such as hydrogen pressure, pressure-cycle frequency, pressure-time relationship (wave form), and temperature.

Although steel pressure vessels may be vulnerable to fatigue crack growth aided by hydrogen embrittlement, the industrial gas companies have used such pressure vessels for hydrogen transport and storage for decades. Typically, these pressure vessels are subjected to less than one pressure cycle per day (and in many cases less than one cycle per month), thus fatigue crack growth is generally not a concern. Pressure vessels for hydrogen storage in new applications such as those for lift trucks are anticipated to experience up to six pressure cycles per day, approaching an order of magnitude greater than the duty cycle of typical transportable industry gas pressure vessels.

Since the duty cycle for lift truck pressure vessels is outside the window of current experience, a methodology for determining the cycle life must be established. A deterministic engineering analysis for quantifying the progression of fatigue cracks is provided in the American Society of Mechanical Engineers (ASME) Boiler and Pressure Vessel Code (Section VIII, Division 3, Article KD-4) and extended to the specific case of high-pressure gaseous hydrogen in Article KD-10. This framework provides a method for conservatively estimating the fatigue cycle life of pressure vessels based on assessment of existing flaws in the pressure vessel. An alternate method has been proposed based on the measured performance of manufactured pressure vessels subjected to pressure cycling coupled with statistical assessment of the quality of the pressure vessels and desired cycle life. These two methods have been referred to as engineering analysis method and performance evaluation method respectively.

Approach

During this project, pressure vessels are being pressure cycled with gaseous hydrogen; the pressure vessels are identical to those in service for fuel cell forklift applications with gaseous hydrogen, with the exception that defects are engineered in some pressure vessels. The engineered defects were designed to simulate manufacturing flaws in the pressure vessels. Engineering analysis methods are being employed to compare the engineering analysis predictions with experimental results from the performance evaluation of full-scale pressure vessels. These efforts have required collaborations with fuel cell system integrators and pressure vessel manufacturers to obtain as-manufactured pressure vessels and produce pressure vessels with engineered defects

for cycle testing, as well as develop a testing plan that reflects relevant engineering conditions, including pressure vessel designs, manufacturing flaws, and pressurization schedules. Additionally, direct participation in standards development activities has been a cornerstone of this effort, in particular with the technical advisory group for CSA’s HPIT1 and the subgroup drafting the language for the pressure vessel appendix in SAE J2579.

Results

Materials Testing

Sandia National Labs measured the rate of fatigue crack growth for three heats of 4130 steels in high-pressure gaseous hydrogen; testing coupons were extracted from pressure vessels supplied by the industrial partners (each heat of material came from a different vendor). Details of these experiments are given in reference [1]. The measured fatigue crack growth rates are shown in Figure 1, showing that all three materials performed nominally the same in gaseous hydrogen. ASME Boiler and Pressure Vessel Code (VIII-3) Article KD-10 requires the testing of three heats of a given steel to demonstrate that the effects of hydrogen are not sensitive to variations in the material’s microstructure or processing history. These measured fatigue crack growth rates are used to predict cycle life using engineering analysis methodologies that quantify crack growth through the vessel wall from manufacturing flaws in the pressure vessel.

Full-Scale Tank Testing

A system was designed and constructed to pressure cycle up to 10 full-scale tanks in parallel at a rate of approximately 250 discrete pressure cycles per day (approximately 5-minute pressure cycle time). The pressure vessels are cycled between 3.4 and 43.8 MPa, with an approximately 2-minute pressure ramp rate, 2-minute hold time at maximum pressure, 30-second depressurization rate,

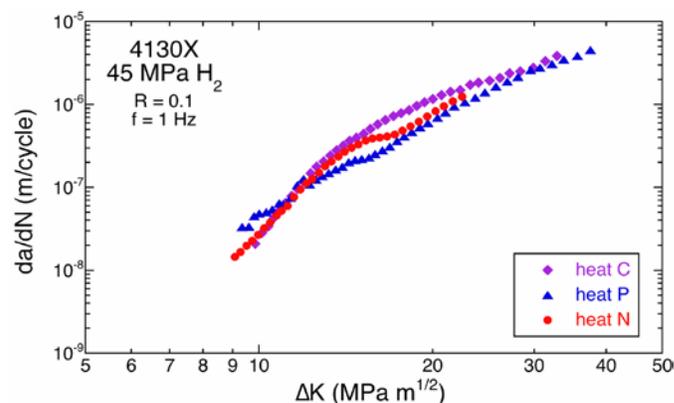

FIGURE 1. Fatigue Crack Growth Rates for three Heats of 4130X Steels (taken from reference [2])

and 30-second hold at minimum pressure. Details of the system, experimental procedures, and additional explanation of results are given in reference [2]. At the time of writing, pressure vessels have cycled for as many as 47,000 cycles without failure, although not all pressure vessels have experienced this number of cycles. Pressure vessels with engineered defects have been subjected to fewer cycles and four vessels have failed after as few as 8,000 cycles. Figure 2 shows the number of cycles that many of the pressure vessels have experienced as a function of the initial defect size for those pressure vessels with engineered defects. Also shown in this figure are the estimates of the cycle life assuming the engineered defects began propagating after the first pressure cycle. Clearly, these estimates underestimate the cycle life. Generally, there are two components to fatigue life, crack initiation and crack propagation. The engineering predictions are based on crack propagation only, since there is no broadly accepted way to account for crack initiation.

Leak-before-burst was observed for each of the four pressure vessel failures. This is an important observation because larger safety factors are generally applied when burst is a probable failure mode. Additionally, postmortem analysis suggests that the engineered defects form cracks that propagate with a semicircular profile (Figure 3), although as the crack depth reaches the full thickness of the vessel the shape again changes (Figure 4). This is also an important observation if shown to be generally true. Cracks with larger aspect ratios (such as the aspect ratio of the engineered defects) propagate at higher rates because the driving force is greater for a “long” crack compared to a “short” crack of the same depth.

These results are currently being discussed in the technical advisory committee for CSA HPIT1. The testing procedures are also being considered in SAE J2579.

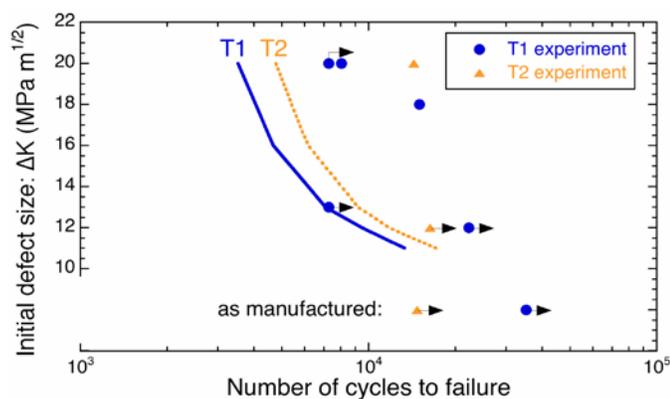

FIGURE 2. The number of cycles to failure in the cycled pressure vessels are given by symbols; arrows indicate that the pressure vessel is still cycling at the time of writing. The curves represent the estimated cycles to propagate the initial defect to a through-wall crack (taken from reference [2]).

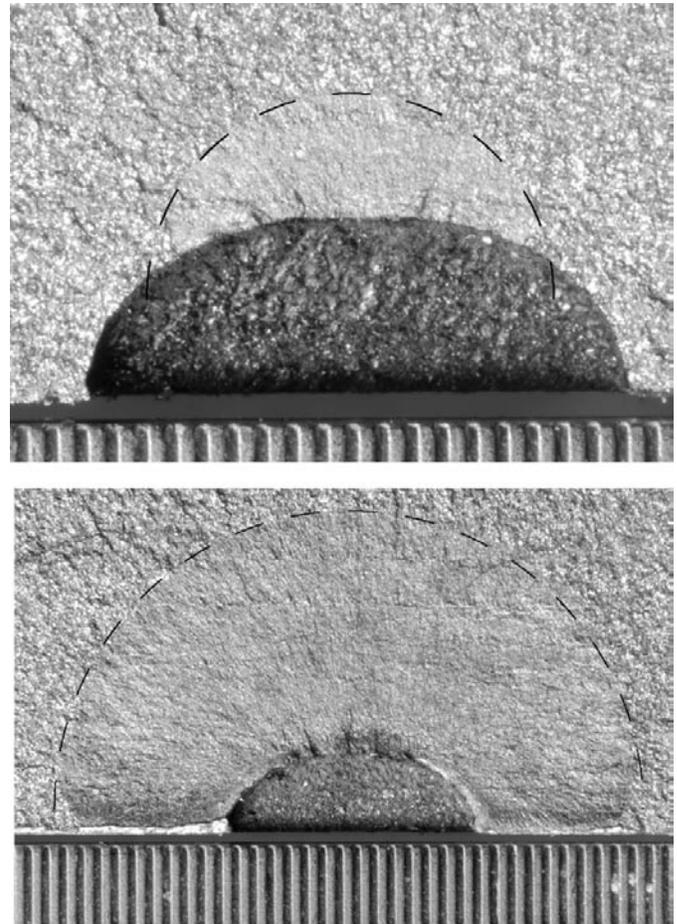

FIGURE 3. Crack extension from engineering defects that did not extend through the thickness of the pressure vessel have a semicircular profile.

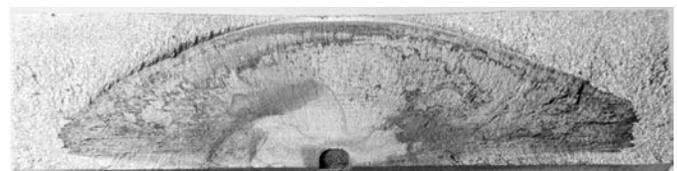

FIGURE 4. Through-wall cracks associated with the engineering defects do not have a semicircular crack profile.

Conclusions and Future Directions

- Commercial pressure vessels being used for hydrogen storage on forklifts have been subjected to more than 47,000 pressure cycles with gaseous hydrogen (between pressure of 3.4 and 43.8 MPa):
 - Primary aim of the remainder of project is to cycle tanks until they fail or reach 50,000 cycles.
- Fatigue crack growth assessment of engineered defects in these pressure vessels using engineering analysis appears to be conservative:

- Post-mortem analysis is being used to refine predictions and interpret failure process.
- Code language based on the test methods developed in this study are being drafted as part of CSA HPIT1 and SAE J2579 for performance based tests:
 - Results are being shared with committees as they are generated.
- Leak-before-burst was observed in all failures.

Sandia National Laboratories is a multi-program laboratory managed and operated by Sandia Corporation, a wholly owned subsidiary of Lockheed Martin Corporation, for the U.S. Department of Energy's National Nuclear Security Administration under contract DE-AC04-94AL85000.

Project End Date: Project continuation and direction determined annually by DOE

- (F) Limited DOE Role in the Development of International Standards
- (G) Inadequate Representation at International Forums
- (H) International Competitiveness
- (I) Conflicts between Domestic and International Standards
- (J) Lack of National Consensus on Codes and Standards
- (K) Lack of Sustained Domestic Industry Support at International Technical Committees
- (L) Competition in Sales of Published Standards
- (M) Insufficient Technical Data to Revise Standards
- (N) Affordable Insurance is Not Available
- (O) Large Footprint Requirements for Hydrogen Refueling Stations
- (P) Parking and Other Access Restrictions

Technical Targets

Table 1 shows the NREL support for achieving DOE technical targets, specifically supporting the development of the codes and standards required to deploy hydrogen and fuel cell technologies. This technical target is described on pages 3.7-1 and 2 of the Codes and Standards – Technical Plan.

Fiscal Year (FY) 2011 Objectives

- Facilitate the safe deployment of hydrogen and fuel cell technologies.
- Identify the codes and standards required to deploy hydrogen and fuel cell technologies. Identify the research and validation testing required to support the development of the needed codes and standards.
- Advance safety, code development, and market transformation through collaboration with appropriate stakeholders.

Technical Barriers

This project addresses the following technical barriers from the Safety, Codes and Standards section (3.7) of the Fuel Cell Technologies Program Multi-Year Research, Development and Demonstration Plan:

- (A) Limited Government Influence on Model Codes
- (B) Competition among SDOs and CDOs
- (C) Limited State Funds for New Codes
- (D) Large Number of Local Government Jurisdictions.
- (E) Lack of Consistency in Training of Officials

FY 2011 Accomplishments

NREL accomplished the following in support of section 3.7 of the DOE Fuel Cell Technologies Program Multi-Year Research, Development and Demonstration Plan:

- NREL supported the development of National Fire Protection Association (NFPA) 2 Hydrogen Technologies Code that was published as a final document January 2011. NREL staff acted as a principal member of the NFPA Hydrogen Technology Technical Committee and acted as task group leader with the planning task group.
- Sensor Workshop: NREL conducted a Sensor Workshop in June 2011. The purpose of the workshop was to review the performance benchmarks set at the 2007 DOE Sensor Workshop and refine them based on defining performance criteria for specific applications. These applications include indoor hydrogen fueling, hydrogen storage, and residential fuel cells and fuel dispensing.
- Component testing: Initiated test work on compressed natural gas (CNG) nozzle failures. The purpose of this project is to determine the root cause for CNG nozzle failures that took place approximately 10 years ago. The concern is that the same failure mechanism may be an issue with hydrogen fueling operations. Test results should be available by the end of FY 2011.

TABLE 1. Progress toward Meeting Technical Targets for Safety Codes and Standards

DOE Accomplishments in Support of the Development of Regulations, Codes and Standards for the Deployment of Hydrogen and Fuel Cell Technologies			
Regulation, Code, or Standard	NREL Support	Status	Time Saved Producing Document (resulting from DOE support)
1. Global Technical Regulation for Fuel Cell Vehicles	Tank testing data, SAE standard that provided basis for document, expert technical support from Dr. Sloane and Glenn Scheffler	Phase 1 work complete in 2011	5 years
2. NFPA 2 Hydrogen Technologies Code	Extensive technical analysis to develop risk informed requirements for siting hydrogen storage systems. Extensive logistical support including support committee chair and consultant producing draft code document	Final document promulgated 2011	3 years
3. International Fire Code (IFC) Section 2209 Hydrogen Motor-Fuel Dispensing and Generation Facilities	Supported Hydrogen Ad Hoc Working Group that wrote section 2209	Final document promulgated 2003	6 years
4. SAE J2579 Technical Information Report (TIR) for Fuel Systems in Fuel Cell and Other Hydrogen Vehicles	Performed validation testing through subcontractor Provided logistical support for SAE Fuel Cell Technical Committee	TIR published 2009	3 years
5. SAE J2601 Fueling Protocols for Light Duty Gaseous Hydrogen Surface Vehicles	Performed validation testing for fueling algorithm in standard. Provided logistical support for SAE Fuel Cell Technical Committee	Standard published 2010	3 years
6. International Organization for Standardization (ISO) 14687 Hydrogen fuel – Product specification – Part 2: Proton exchange membrane fuel cell applications for road vehicles, SAE J2719 – Development of a Hydrogen Quality Guideline for Fuel Cell Vehicles	Extensive test data, logistical support, and coordination of ISO/SAE standard development activities	Both documents will likely be issued as final in 2011	5 years
7. CSA Standards H series of component standards for hydrogen dispensing operations and onboard vehicle safety	Extensive logistical support as well as validation testing of the high-pressure relief device standard	Documents published as drafts to be issued as final documents in 2011 and 2012 for hydrogen gaseous vehicle 4.3	6 years
8. American Society of Mechanical Engineers B31.12 Hydrogen Piping and Pipelines	Provided test data and logistical support	Final document 2008	3 years
9. Compressed Gas Association Hydrogen Documents including G-5 through G5-8	Provided logistical support	Documents issued 2004 through 2007	3 years

- Fuel quality specification: NREL continued to support the promulgation of ASTM standards that require contaminant testing to show compliance with the ISO standard through funding the production of calibration gases required to verify the ASTM test methods. Additionally, NREL supported the work of Michael Steele, Chairman of the SAE Fuel Cells Technical Committee, who has produced an Information Report on the development of a hydrogen quality guideline for fuel cell vehicles.
- Codes and standards coordination: NREL continued to support the coordination of codes and standards development through software that identified the

standards development organizations (SDOs) and code development organizations (CDOs) involved in hydrogen and fuel cell technologies codes and standards development. NREL has updated this software to include current project information.

- Subcontract Management: NREL assumed responsibility for several additional subcontracts. NREL staff developed new statements of work for these subcontracts that reflect DOE priorities and budget constraints.

Introduction

It is essential to develop and promulgate codes and standards in order to provide for the safe use of hydrogen and fuel cell technologies. With the help of key stakeholders, the DOE Fuel Cell Technologies (FCT) Program and NREL are coordinating a collaborative national effort to prepare, review, and promulgate codes and standards for all hydrogen and fuel cell technologies.

Approach

The FCT program recognizes that domestic and international codes and standards must be established to enable the timely commercialization and safe use of hydrogen and fuel cell technologies. The lack of codes and standards applicable to hydrogen and fuel cell technologies is an institutional barrier to deploying these technologies. It is in the national interest to eliminate this potential barrier. As such, the sub-program works with domestic and international SDOs to facilitate the development of performance-based and prescriptive codes and standards. These standards are then referenced by building and other codes to expedite regulatory approval of hydrogen and fuel cell technologies. This approach ensures that United States (U.S.) consumers can purchase products that are safe and reliable, regardless of their country of origin, and that U.S. companies can compete internationally by having coordinated consistent requirements.

Results

The Safety, Codes and Standards work is divided into three major areas:

1. Codes and Standards Coordination
2. Codes and Standards Research
3. Codes and Standards Training and Outreach

This report addresses the National Template.

Codes and Standards Coordination

Figure 1, Hierarchy of Codes and Standards Implementation, shows both the hierarchy for enforcing codes and standards and some of the progress made in promulgating the codes and standards required to implement hydrogen and fuel cell technologies. Figure 2 shows the front page of the coordinating software NREL has developed to track codes and standards development activities.

In FY 2011 substantial progress was made in this implementation effort. NFPA 2 Hydrogen Technologies Code was published as a final document in January 2011. NREL will be working on coordinating the requirements of NFPA 2 with the hydrogen requirements in the IFC through a proposal to reference NFPA 2 in the 2015 edition of the IFC. NREL supported the development of NFPA 2 in several ways, including:

- Participated as a principal member of the technical committee.
- Funded subcontractors actively participating in the development of the document such as FP2 Fire Protection Engineering.
- Hosted Report on Comment meeting.

Another important part of codes and standards is the development of hydrogen fueling station component and system standards being performed by CSA Standards. These H-4 series of documents consists of nine component standards and one system standard that addresses hydrogen dispensing. An NREL staff member participated as a member of the CSA technical committee drafting these documents.

NREL supports the Fuel Cell and Hydrogen Energy Codes and Standards Coordinating Committee by coordinating and directing monthly meetings where SDOs,

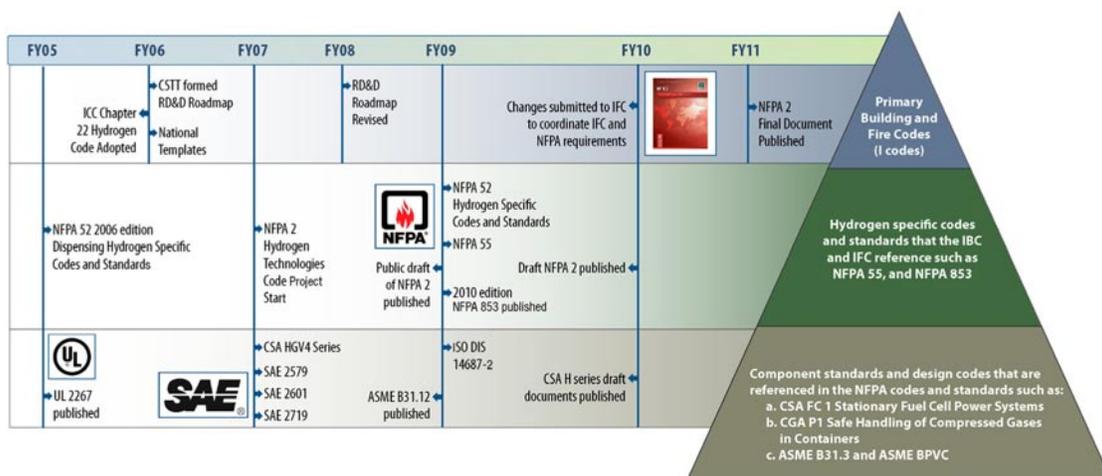

FIGURE 1. Hierarchy of Codes and Standards Implementation

FIGURE 2. NREL Codes and Standards Coordinating Software

DOE laboratories, industry representatives, DOE and other interested parties are given topical information on codes and standards development activities.

NREL also supports the Hydrogen Industry Panel on Codes that has as its primary objective the coordination of hydrogen safety requirements in the IFC and other key International Code Council codes such as the International Building Code and the NFPA hydrogen safety requirements that reside primarily in NFPA 2.

NREL supports both the development of fuel quality standards through acquiring test data and coordinating the activities of the ISO Technical Committee 197 and the SAE Fuel Cell Technical Committee. These efforts resulted in the promulgation of SAE J2719.

Conclusions and Future Direction

NREL will continue to support the development of codes and standards by:

- Working with DOE to implement a plan for identifying and supporting the development of the codes and standards required to deploy hydrogen and fuel cell technologies with a particular emphasis on road vehicles by the year 2020 (the 2020 Deployment Plan).
- Continuing research and development at the NREL Sensor Laboratory to support the development of sensors required to deploy hydrogen and fuel cell technologies.
- Managing subcontracts required to support the 2020 Deployment Plan.
- Performing outreach work to distribute information on hydrogen and fuel cell technologies to code officials, project developers, and other interested parties.
- Coordinating domestic codes and standards and international standards to ensure consistent requirements.

Technical Targets

Table 1 shows the NREL support for achieving DOE technical targets, specifically supporting the development of the codes and standards required to deploy hydrogen and fuel cell technologies. This technical target is described on pages 3.7-1 and 2 of the Codes and Standards – Technical Plan.

Fiscal Year (FY) 2011 Objectives

- Facilitate the safe deployment of hydrogen and fuel cell technologies.
- Provide information on hydrogen and fuel cell technologies codes and standards to code officials, project developers, and other interested parties.
- Present workshops on hydrogen and fuel cell technologies codes and standards to code officials, project developers, and other interested parties in geographic areas where these technologies are being deployed.
- Develop tools to streamline the permitting process for fuel cell and hydrogen technology projects.
- Perform site visits to fuel cell and hydrogen technology project sites to obtain safety, codes and standards information for publication in technical reports.
- Present safety, codes and standards information on DOE websites and through webinars.

Technical Barriers

This project addresses the following technical barriers from the Safety, Codes and Standards section (3.7) of the Fuel Cells Technologies Program Multi-Year Research, Development and Demonstration Plan:

- (A) Limited Government Influence on Model Codes
- (B) Competition among SDOs and CDOs
- (C) Limited State Funds for New Codes
- (D) Large Number of Local Government Jurisdictions.

TABLE 1. Progress towards Meeting Technical Targets for Safety Codes and Standards

DOE/NREL Accomplishments in Support of the Development of Regulations, Codes and Standards for the Deployment of Hydrogen and Fuel Cell Technologies Outreach Activities		
Activity	Primary Impacted Groups	Progress Towards Meeting DOE Targets
Safety Codes and Standards Workshops	Code officials, project developers, and other interested parties	Workshops make information available to expedite process for developing and permitting fuel cell and hydrogen technology projects
Sensor Workshop	Sensor developers, project managers	Improve performance of sensors to increase project safety
Updating codes and standards citations on DOE websites	Code officials, project developers, and other interested parties	Web information make information available to expedite process for developing and permitting fuel cell and hydrogen technology projects
Permitting template for hydrogen dispensing stations	Code officials and project developers	Standardized permitting will streamline permitting for fuel cell and hydrogen technology projects
Hydrogen dispensing station site visit and technical report	Project developers	Improve fuel cell and hydrogen codes and standards by identifying safety issues that can be addressed by codes and standards modifications

Accomplishments

NREL accomplished the following in support of section 3.7 of the DOE Fuel Cell Technologies Program Multi-Year Research, Development and Demonstration Plan:

- **Sensor Workshop:** NREL conducted a Sensor Workshop in June 2011. The purpose of the workshop was to review the performance benchmarks set at the 2007 DOE Sensor Workshop and refine them based on defining performance criteria for specific applications. These applications include indoor hydrogen fueling, hydrogen storage, and residential fuel cells and fuel dispensing.
- **Web Updates:** NREL updated the codes and standards citations on the DOE website. Additionally, NREL streamlined the website by removing redundant material.
- **Codes and Standards Workshops:** NREL conducted a Codes and Standards Workshop on April 19, 2011 in collaboration with the California Fuel Cell Partnership and the Southern California Fire Protection Officers Association. Attendees at this workshop included fire service representatives from several of the key jurisdictions in the Los Angeles metropolitan area.
- **Permit Template for Hydrogen Dispensing Stations:** NREL developed a permitting template for hydrogen dispensing stations that contains the basic codes and standards requirements used across the United States (U.S.) jurisdictions can modify this template to create a standard permit for hydrogen dispensing stations.
- **Hydrogen Dispensing Station Site Visit:** NREL performed a site visit to a hydrogen dispensing station to evaluate code compliance and safety issues. The results of the visit will be documented in a NREL Technical Report.

Introduction

It is essential to develop and promulgate codes and standards in order to provide for the safe use of hydrogen and fuel cell technologies. With the help of key stakeholders, the DOE Fuel Cell Technologies Program and NREL are coordinating a collaborative national effort to prepare, review, and promulgate codes and standards for all hydrogen and fuel cell technologies. To complement this codes and standards development effort, NREL is conducting outreach activities to inform code officials, project developers, and other interested parties of these codes and standards requirements.

Approach

Domestic and international codes and standards must be established to enable the timely commercialization and safe use of hydrogen and fuel cell technologies. The lack

of codes and standards applicable to hydrogen and fuel cell technologies is an institutional barrier to deploying these technologies. It is in the national interest to eliminate this potential barrier. As such, the sub-program works with domestic and international standards development organizations to facilitate the development of performance-based and prescriptive codes and standards. These standards are then referenced by building and other codes to expedite regulatory approval of hydrogen and fuel cell technologies. This approach ensures that U.S. consumers can purchase products that are safe and reliable, regardless of their country of origin, and that U.S. companies can compete internationally by having coordinated consistent requirements.

Results

The Safety Codes and Standards work is divided into three major areas:

1. Codes and Standards Coordination
2. Codes and Standards Research
3. Codes and Standards Training and Outreach

This report addresses the Outreach activities

Codes and Standards Outreach

In FY 2011 NREL continued outreach work in both in-person workshops and Web activities. The workshops and other outreach activities consisted of the following:

- Codes and Standards Workshop presented on April 19, 2011 in collaboration with the California Fuel Cell Partnership and the Southern California Fire Protection Officers Association.
- Sensor Workshop held June 8, 2011 in Rosemont, IL. This workshop was well attended and achieved the objective of collecting information to revise the performance criteria for safety sensors.
- Incident Workshop to be held September 2011.
- Codes and standards citations were updated for DOE website.
- Codes and standards permit template for hydrogen fueling stations completed.

Figure 1 shows the invitation for the April 2011 workshop. The invitation describes the material that was covered and workshop partners.

Conclusions and Future Direction

NREL will continue to support the development of codes and standards by:

- Working with DOE to implement a plan for identifying and supporting the development of the codes and

Hydrogen and Renewable Energy Technologies Codes and Standards Workshop
with an emphasis on permitting hydrogen fueling stations

The Department of Energy (DoE), through the National Renewable Energy Laboratory (NREL), invites you to participate in a one-day, invitation-only workshop to address codes and standards issues associated with hydrogen technologies, particularly hydrogen fueling stations, and other renewable energies.

To encourage interaction and open discussion, we are limiting the invitees of this workshop to active participants consisting of building, fire and electrical code officials. We are expecting a diverse group for this workshop, providing code officials and industry experts the ability to work together to identify areas for improvement in the plan review and permitting of these installations.

We hope you will be able to join us for this free workshop to learn more about the emerging uses of hydrogen and other renewable energies. The discussion and outcomes of this workshop are vital to our communities and our nation as we proceed in transitioning to a greater use of hydrogen and renewable energies.

Date & Time:
Tuesday, April 19, 2011
9:00 am – 4:00 pm
Continental Breakfast & Lunch will be served

Location:
Gordon Hoyt Training Center – 2nd floor
Anaheim West Tower
201 S. Anaheim Boulevard
Anaheim, CA 92805
Room: Gordon Hoyt Training Room

Project Start Date: Fiscal Year (FY) 2008

Project End Date: FY 2012

FY 2011 Objectives

- Develop a low-cost, low-power, durable, and reliable hydrogen safety sensor for vehicle and infrastructure applications.
- Demonstrate working technology through application of commercial and reproducible manufacturing methods and rigorous life testing results guided by materials selection, sensor design, and electrochemical research and development investigation.
- Recommend sensor technologies and instrumentation approaches for engineering design.
- Disseminate packaged prototypes to DOE laboratories and commercial parties interested in testing and fielding advanced commercial prototypes while transferring technology to industry.

Multi-Year Program Plan Technical Barriers from the Hydrogen Safety section (3.8) of the Fuel Cell Technologies Program

- (D) Liability Issues: Potential liability issues and lack of insurability affecting the commercialization of hydrogen technologies: need for reliable H₂ safety sensor.
- (A) Variation in Standard Practice of H₂ Safety Assessments: The requirement to calibrate and commercialize safety sensors.
- (G) Expense of Data Collection and Maintenance

Technical Targets

- Sensitivity: 1 vol % in air.
- Accuracy: 0.04-4% ± 1%.
- Response Time: <1 min at 1% and <1 sec at 4%; recovery <1 min.
- Temperature: -40°C to 60°C.
- Durability: Five years without calibration.
- Cross-Sensitivity: Minimal interference to humidity, H₂S, CH₄, CO, and volatile organic compounds.

FY 2011 Accomplishments

- Completed testing of FY 2009 and FY 2010 laboratory and pre-commercial prototypes for long-term evaluation (>3,000 hrs, LLNL and 4,000 hrs, LANL including temperature cycling) including comparison of mixed potential and impedance modality in laboratory prototypes: down-select to mixed potential.
- For laboratory prototypes, evaluated impregnated composite electrodes for better long-term stability and demonstrated stability and reproducibility to over 3,000 hrs in laboratory testing.
- Designed more advanced sensor substrates incorporating on-board temperature control and completed initial calibration procedures for pre-commercial prototypes.
- Effective packaging scheme adopted for pre-commercial prototypes.
- Partnered with BJR Sensors and co-developed an algorithm using a novel approach to eliminate the cross interference affecting existing technologies.
- Fabrication of multiple pre-commercial prototype devices for National Renewable Laboratory (NREL) testing; six devices prepared with high level of reproducibility.
- First round of devices shipped to NREL for testing; devices returned and durability studied.
- Positive NREL feedback already used to improve sensor platforms and to prepare for Round 2 NREL testing – focus on electronics.
- Calculated an estimate of sensor element cost for large scale up in production.
- Designed and constructed prototype sensor electronics (impedance buffer and controlled heater circuit) in preparation of Round 2 NREL testing.

Introduction

Recent developments in the search for renewable energy coupled with the advancements in fuel cell vehicles (FCVs) have augmented the demand for hydrogen safety sensors [1]. There are several sensor technologies that have been developed to detect hydrogen, including deployed systems to detect leaks in manned space systems and hydrogen safety sensors for laboratory and industrial usage. Among the several sensing methods electrochemical devices [2-8] that utilize high temperature-based ceramic electrolytes are largely unaffected by changes in humidity and are more resilient to electrode or electrolyte poisoning. The desired sensing technique should meet a detection threshold of 1% (10,000 ppm) H_2 and response time of ≤ 1 sec [9] targets for infrastructure and vehicular. Further, a review of electrochemical hydrogen sensors by Korotcenkov et al [10] and the report by Glass et al [11] suggest the need for inexpensive, low power, and compact sensors with long-term stability, minimal cross-sensitivity, and fast response. As part of the Hydrogen Codes and Standards sub-program, LANL and LLNL are working together to develop and test inexpensive, zirconia-based, electrochemical (mixed potential) sensors for H_2 detection in air. Previous work conducted at LLNL showed [8] that indium tin oxide (ITO) electrodes produced a stable mixed potential response in the presence of up to 5% of H_2 in air with no response to CO_2 or water vapor. The sensor also showed desirable characteristics with respect to response time and resistance to aging, and degradation due to thermal cycling.

In this investigation, the development and testing of an electrochemical H_2 sensor prototype based on 'ITO/yttria-stabilized zirconia (YSZ)/Pt' configuration is detailed. The device fabricated on an alumina substrate integrates a resistive Pt heater to achieve precise control of operating temperature while minimizing heterogeneous catalysis. Targeting fuel cell-powered automotive applications, the safety sensor was subjected to interference studies, temperature cycling, operating temperature variations, and long-term testing over 4,000 hrs. The sensor responded in real time to varying concentrations of H_2 (1,000 to 20,000 ppm). Among the interference gases tested such as nitric oxide (NO), nitrogen dioxide (NO_2), ammonia (NH_3), carbon monoxide (CO), and propylene (C_3H_6), the sensor showed cross-sensitivity to C_3H_6 . Analyzing the overall device performance over 4,000 hrs of testing for 5,000 ppm of H_2 , (a) the sensitivity varied between 0.135 to 0.17 V with a minimum low of 0.12 V, (b) the baseline signal ranged from 0 to 0.04 V, and (c) the response rise time fluctuated between 3 to 47 s.

The salient features of the H_2 sensor prototype developed by LANL are (a) the low power consumption, (b) compactness to fit into critical areas of application, (c) simple operation, (d) fast response, (e) a direct voltage read-out circumventing the need for any additional conditioning circuitry, and (f) conducive to commercialization.

Approach

The sensor design approaches from LANL and LLNL were used to develop devices with superior performance.

LANL Design: Controlled Electrode/Electrolyte/Gas Interface

At LANL, electrochemical potentiometric modality is utilized for designing the sensors. Mixed potential sensors are a class of electrochemical devices that develop an open-circuit electromotive force due to the difference in the kinetics of the redox reactions of various gaseous species at each electrode/electrolyte/gas interface, referred to as the triple phase boundary [12]. Therefore these sensors have been considered for the sensing of various reducible or oxidizable gas species in the presence of oxygen. Based on this principle, a unique sensor design was developed. The uniqueness of LANL sensors [13] derives from minimizing heterogeneous catalysis (detrimental to sensor response) by avoiding gas diffusion through a catalytically active material and minimizing diffusion path to the 3-phase interface (electrode/electrolyte/gas referred to as tripe phase boundary). Unlike the conventional design of these devices that use a dense solid electrolyte and porous thin film electrodes (similar to the current state-of-the-art zirconia-based sensors and fuel cells), the LANL design uses dense (either metal wires, oxide pellets or thin film) electrodes and porous electrolytes (bulk or thin film). Such a sensor design facilitates a stable and reproducible device response, since dense electrode morphologies are easy to reproduce and are significantly more stable than the conventional porous morphologies. Moreover, these sensors develop higher mixed potentials since the gas diffusion is through the less catalytically active electrolyte than the electrode. Further, the choice of electrodes is primarily based on their O_2 reduction kinetics. Sensors fabricated at LANL will typically involve one electrode with fast (Pt) and another with slow (Au or $LaCrO_3$) O_2 reduction kinetics aimed to improve the sensitivity.

LLNL Design

In the LLNL design, a new impedance-based measurement technique, originally developed for electrochemical oxides of nitrogen (NO_x) sensors, was shown to generate more stable sensor responses and may be able to offer a way to compensate for cross-sensitivity effects. The technique is based on the measurement of parameters related to the complex impedance of the sensor in the frequency range of 1 Hz to 10 kHz. Measurements are typically made at a single frequency selected to maximize the desired sensitivity, although measurements performed at additional frequencies have been shown to be useful for correcting the response to interfering gases. LLNL has also found in the NO_x sensor studies that it may be possible to use a wider variety of electrodes for the sensor in

impedance-based sensing. Additional possible advantages included better tolerance to mechanical defects (such as delamination) and better longer-term stability.

Results

Commercial Platform Packaging and Preparation of Multiple Devices

In order to facilitate the transfer of sensors to testing partners, a ceramic packaging was devised. A two-piece packaging made from a commercial machinable ceramic material. The sensor element was supported from its heater and sense wires using four metal posts that protruded from the case such that long lead wires could easily be soldered to the device. A ceramic cap with a 0.5" stainless-steel mesh was then affixed to the lower packaging using a ceramic adhesive. Figure 1 shows the completed, 1" diameter, packaged H_2 sensor. The packaging is insulating and at normal sensor operating temperature, the safety sensor may be handled comfortably without personal protective equipment.

A new method of characterizing hydrogen sensor response was developed to test sensor response in a non-flow, safety sensor mode. Figure 2 illustrates the approach adopted in preparation to transferring sensors to NREL for independent testing and validation. The sensors were placed into a 1.7 ft³ plexiglas enclosure with dry or humidified air entering through a 0.25" pass-through. The enclosure was fitted with several 0.25" pass-through holes for venting. When commended to do so, H_2 was added to the air stream such that resulting hydrogen concentration was 2%. Figure 2 also shows the sensor response and the actual hydrogen concentration present immediately in front of the packaged sensor.

A total of six packaged H_2 sensors were prepared (four with ITO working electrode and two with lanthanum

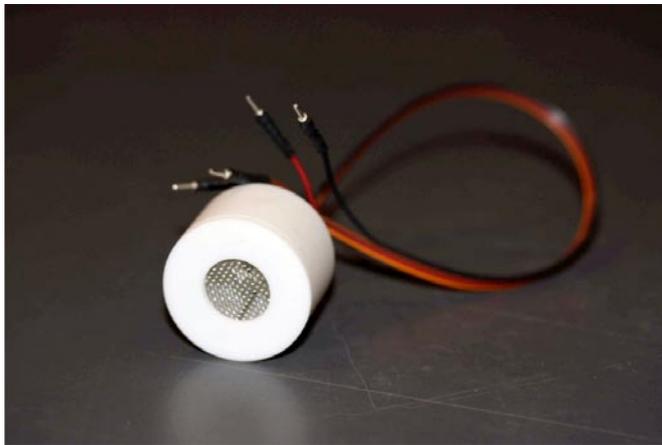

FIGURE 1. Photograph of a Packaged LANL/LLNL Mixed-Potential, Electrochemical H_2 Safety Sensor

manganese oxide working electrodes) for parallel testing at LANL, LLNL, and NREL.

Transfer of Packaged, Pre-Commercial H_2 Safety Sensors to NREL for Testing

Two packaged, pre-commercial H_2 safety sensors were shipped in October 2010 to NREL for testing and validation (Figure 3). Earlier, a mock-up of the packaging without sensor element was shipped to NREL to insure that test ports on the NREL apparatus would accept the LANL/LLNL sensors without complications. Testing commenced in January of 2011 and one of the heater leads of one of the packaged sensors broke during transport. That sensor was quickly replaced with a back up unit. The sensor's response to H_2 , relative humidity influence, barometric pressure, and changes in ambient temperature were subsequently

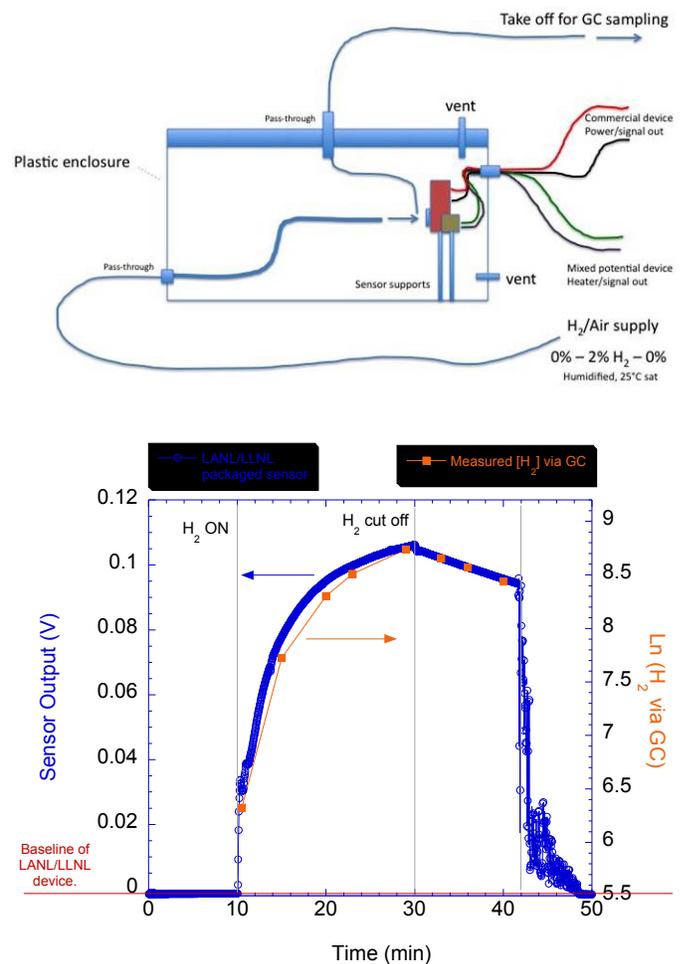

FIGURE 2. (top) A schematic of a test 1.7 cubic ft test enclosure of testing a pre-commercial, electrochemical-based LANL/LLNL H_2 sensor simultaneously with other technologies while extractive gas chromatograph measures actual hydrogen concentrations. (bottom) The response of a packaged, pre-commercial LANL/LLNL sensor while simulating a leak of hydrogen (2% H_2 /air mix) into the enclosure.

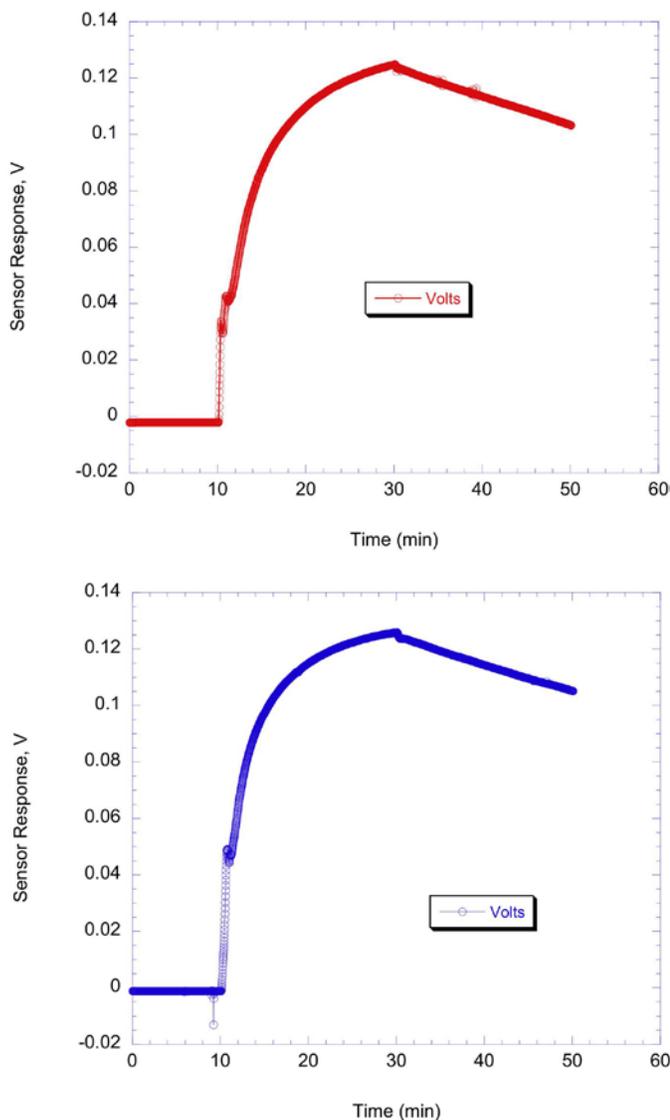

FIGURE 3. Comparison of the response of two packaged LANL/LLNL H_2 sensors to identical experiment profiles. Due to slight differences in positioning of the sensor element within the packaging and possible differences in heater resistance, the applied heater currents differed slightly (5 V/0.64 A top and 5 V/0.65 A bottom).

measured. The behavior of both sensors were similar as was predicted based on results shown in Figure 2. The sensors' response were insensitive to changes in relative humidity and the H_2 response to changes in ambient temperature of the testing chamber were as predicted (these devices did not have active temperature control). This latter result will be corrected once active temperature control is available using resistive thermal device (RTD) embedded in the sensor platform. However, there was a large non-zero baseline voltage not previously seen in these devices. This anomalous baseline voltage in air (no hydrogen) has never been seen at sensor testing at LANL or LLNL and may be attributed to impedance mismatches with the data acquisition system or

FIGURE 4. Custom-designed sensor impedance buffer circuit to isolate electrochemical sensor from external electrical influences. Photograph provided by Custom Sensor Solutions, Inc.

stray currents or voltages in some component of the NREL system since both sensors did not exhibit this behavior upon return to LANL after NREL testing. Based on these experimental results, a new high impedance/buffer circuit was designed to isolate the sensors from external influences. In addition, a circuit was designed to use the RTD output to control sensor operating temperature thus eliminating sensor response to changes in ambient testing temperature in the next round of testing at NREL.

Sensor Electronics: Circuit Design/Prototyping

Figure 4 shows an actual photograph of the completed high impedance buffer board. As of this report, multiple boards have been received from Custom Sensor Solutions, Inc. and compatible shielding and cables are being selected prior to testing and optimization. New, packaged sensors will be prepared and tested using this circuitry. Once the baseline response is well characterized on sensor test stations at LANL and LLNL (with and without impedance buffer to understand what effect – if any – the circuit has on sensor response), sensors and electronics will be transferred to NREL for the next round of testing/validation.

Conclusions

- All FY 2011 milestones on target to be completed this year.
- Improved electrode materials with potentially better performance were investigated where dense electronically conducting oxide (lanthanum strontium manganite) counter electrode showed better long-term stability.
- An alternate impedancemetric sensing modality was explored to evaluate improvements in long-term performance and stability.
- A viable H_2 safety sensor technology has been developed on a pre-commercial sensor platform that continues to

improve. A pre-commercial H₂ sensor prototype was fabricated on an alumina substrate with ITO and Pt electrodes and YSZ electrolyte with an integrated Pt heater to achieve precise operating temperature and minimize heterogeneous catalysis.

- A sensor platform cost analysis was performed by commercialization partner (scale up of existing pre-commercial platform to production of 100K and 500K units) and sensor cost estimated to be in the \$6 to \$9 range in line with a modern automotive lambda sensor.
- Multiple sensors were prepared and packaged that exhibited excellent response and device-to-device reproducibility.
- Sensors were prepared and transferred to NREL for independent testing and validation. Valuable feedback was obtained and used to design sensor isolation/impedance matching electronics and for sensor heater control.
- Device technology advanced from naked sensor to near-commercial state.
- Novel attributes of mixed electrochemical, mixed-potential sensor exploited in conjunction with novel pulse discharge technology as a method to reject influence from interference gases.

Future Directions

- Fabricate new sensors on platform with embedded temperature feedback sensor (RTD).
- Improve pre-commercial sensors and packaging using results from NREL testing.
- Work with NREL partners to develop testing protocols for mixed potential type, electrochemical gas sensors.
- Work with NREL to test prototype electronics (circuit and board design validation) for mixed potential type, electrochemical gas sensors:
 - Fabricate electronics to protect sensors from external influences, leakage currents, etc.
 - Impedance matching and signal amplification, baseline adjustment, etc.
 - Design and test constant resistance feedback circuit for temperature control.
- Utilize on-board RTD and incorporate active temperature control for next round of NREL testing.
- Provide new sensors and electronics to NREL for Round 2 testing.

Collaboration and Coordination with Other Institutions

Project Start Date: October 2006
Project End Date: Project direction and continuation determined annually by DOE

- Provide testing results from Common membrane electrode assembly (MEA) in the presence of critical constituents.
- Measure the fuel cell tolerance to carbon monoxide using Common MEAs.
- Identify MEA manufacturer to provide Common MEA DOE 2015 target loadings.
- Perform baseline test with lower anode loading MEAs.
- Participation in domestic and international working groups and review meetings.

Approach

We approached our 2011 technical targets by conducting multiple fuel cell tests mimicking conditions that a fuel cell may be subjected to in vehicular applications. Initially, we employed 'Common MEAs' to perform these tests with 0.1 and 0.4 mg Pt/cm² loadings on the anode and cathode, respectively. Although, these loadings are not identical to the DOE targets (0.05 and 0.15 mg Pt/cm²), the results provide a means for comparing different testers and facilities. These results were presented and discussed at several forums throughout the year. In addition, commercial suppliers of the DOE 2015 technical target loadings were being identified and, the preliminary testing steps were put in place to qualify their materials.

FY 2011 Accomplishments

- Completed multiple tests under various conditions using calibrated quantities of the critical constituents.
- Measured CO tolerance level of Common MEA.
- Interacted with multiple industrial, university, or laboratory partners, as well as international collaborators.
- Identified Ion Power as the Common MEA supplier for DOE 2015 platinum loadings.
- Performed initial baseline tests to qualify lower loaded MEAs.

Results and Discussions

The development of international hydrogen fuel specifications has been discussed for several years. In particular, the focus has been on determining the acceptable level of non-hydrogen constituents. LANL researchers have continued fuel cell testing at the agreed upon contaminant levels using a Common MEA loaded at 0.1 and 0.4 mg Pt/cm² under various operating conditions. Although the loadings mentioned are slightly higher than DOE

Fiscal Year (FY) 2011 Objectives

- Provide data and analysis to the international effort to determine the levels of non-hydrogen constituents in support of the development of an international standard for H₂ fuel quality.
- Test the critical constituents (NH₃, CO, and H₂S).
- Isolated and combined at various conditions.
- Present data and have open discussions at International Organization for Standardization (ISO) TC197/Working Group 12 Meetings.
- Solicit guidance from leading industrial experts.

Technical Barriers

This project is directed to ameliorate many of the technical barriers from the Codes and Standards section (3.7) of the Fuel Cell Technologies Program Multi-Year Research, Development and Demonstration Plan, however it is focused on the following primary barriers:

- (I) Conflicts between Domestic and International Standards
- (N) Insufficient Technical Data to Revise Standards

Technical Targets

Technical targets in Table 3.4.4 of the Fuel Cell Technologies Program Multi-Year Research, Development and Demonstration Plan are addressed in this project. Specifically, select tasks that apply to the technical targets in this project are listed in the following, while their status is listed in the Accomplishments section.

targets, the results are useful. Previous tests results with contaminant mixtures showed that the fuel cell performance losses were due to hydrogen sulfide (H_2S), ammonia (NH_3), and carbon monoxide (CO). These are referred to as ‘critical constituents’. Our fuel cell test results include investigating the critical constituents both isolated and combined.

H_2S has a strong affinity for platinum surfaces and blocks the dissociative chemisorption of hydrogen on the electrode surface. This platinum-sulfur interaction inhibits the hydrogen electrooxidation process, which consequently reduces fuel cell performance. In separate experiments, we exposed the anode of operating fuel cells to both 4 and 8 ppb for 50 hours each. The fuel cells operated in constant current mode ($1 A/cm^2$) at $80^\circ C$, 100% relative humidity (RH) and 25 psig backpressure. We performed polarization experiments before and after sulfide exposure. After 50 hours of exposure, the fuel cell did not show performance loss in the presence of 4 ppb, however the performance is progressively depressed when the concentration of H_2S was increased. This effect is demonstrated in Figure 1. As expected, we did not observe any change in the alternating current (AC) high frequency resistance. However, in the low frequency charge transfer region, the semi-circle grew as the H_2S concentration increased. This implies the sulfur coverage on the platinum surface also increased with concentration. Cyclic voltammetry (CV) also confirmed this finding. Also, in the mass transport region, we observed unexpected losses for 4 PPB H_2S . This result is being further investigated.

In order to study the effect of CO concentration upon fuel cell performance, we exposed a fuel cell with an anode loading of either 0.05 or $0.1 mg Pt/cm^2$ to several different concentrations at $80^\circ C$. We kept the dosage in each experiment constant ($20 ppm\text{-hr CO}$) by varying both concentration and exposure times. CVs were used to clean the platinum surface after CO exposure following each experiment. The CVs were performed, with ultra-high purity (UHP) N_2 flowing through the anode and UHP H_2 flowing through the cathode after pre-purging the cathode for 20 minutes with UHP N_2 . The scan rate was $20 mV/s$ and the applied voltage ranged between $0.06 V$ and $1.1 V$ for 4 cycles. The cleaning procedure allowed us to use the same cell in subsequent experiments. Figure 2 shows the experimental results for a Pt loading of $0.1 mg Pt/cm^2$ for the differing concentrations of CO. We also measured the voltage loss for each test and plotted it as a function of CO concentration. This allowed us to extrapolate the point at which the voltage loss approaches zero; the concentration under these tested conditions, that the fuel cell is tolerant to CO. Figure 2 highlights these results. Similar experiments were performed at $60^\circ C$ and $45^\circ C$.

Ammonia is yet another important impurity constituent deemed critical in this effort. It typically reacts with proton in the ionomer forming ammonium cations and affects the ionomer throughout the MEA by lowering its conductivity. Figure 3 illustrates the impact of a variety of ammonia concentrations and RH. Tests were carried out at $50 A$

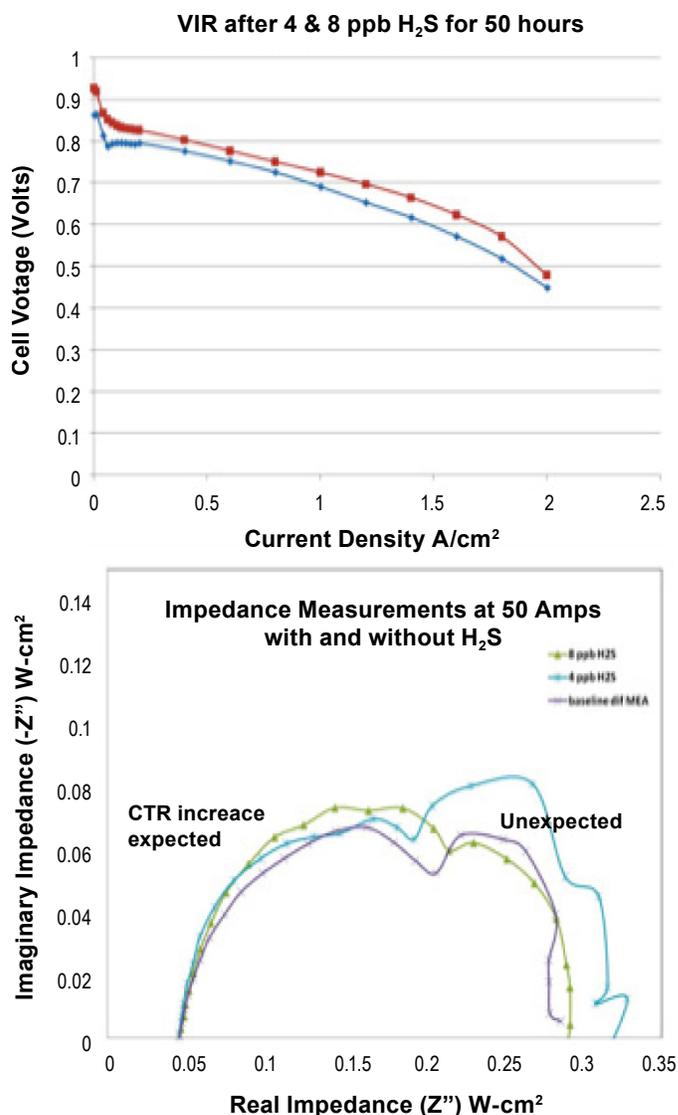

FIGURE 1. Voltage-current-resistance tests and AC Impedance measured using the Common MEA after being exposed to 4 and 8 ppb of hydrogen sulfide for 50 hours.

(constant current mode) using 25 psig backpressure. We used three different concentrations: 100, 200, and 500 ppb. The RH ranged from 25 to 100%. The entire data set is not included in this report, but the findings indicate that the performance decreases as the concentration of ammonia is increased. Because ammonia is water soluble, as the RH increased for identical concentrations, the performance losses decreased from 24 mV at 25% RH to 8 mV at 50% RH (see Figure 3).

The previously mentioned results were obtained from Common MEAs with Pt loading greater than the DOE targets. This year, we identified Ion Power as a commercial supplier to provide MEAs at DOE targeted loadings. We ran preliminary test to investigate the durability of the new materials. Figure 4 shows VIR tests completed 150 hours

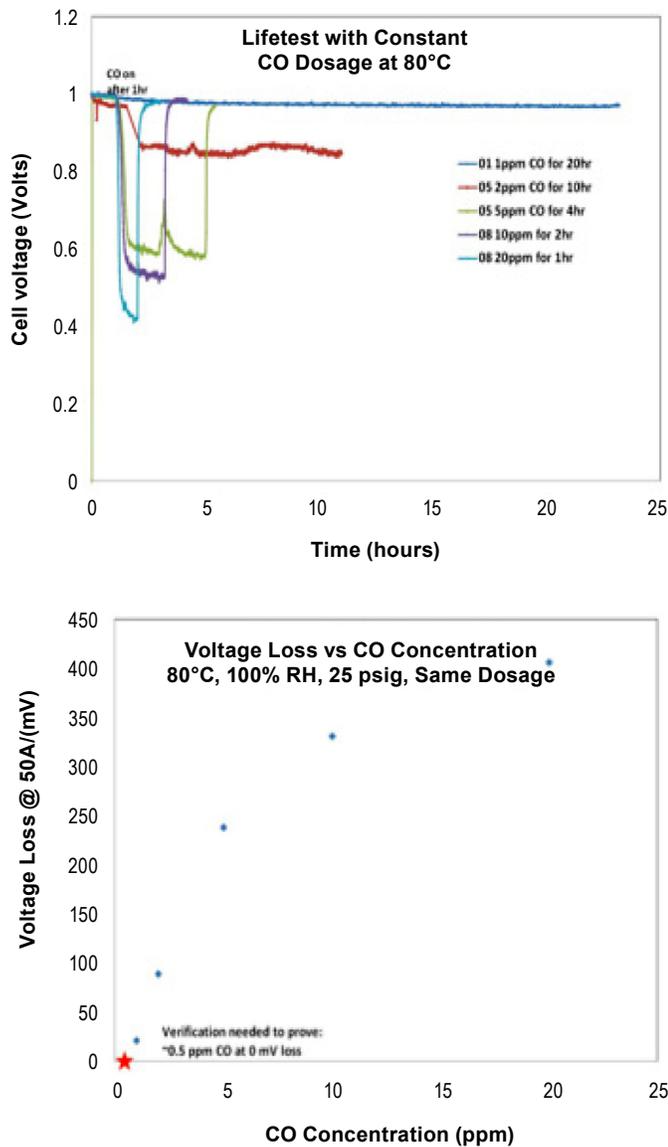

FIGURE 2. Results show the impact of CO on an operating fuel cell using identical doses. The adjacent graph allows the CO tolerance level to be extrapolated.

apart. The performance improved during that period. This indicates the MEA was fully broken in at 150 hours. However, more importantly, this result demonstrated membrane durability. We also performed other preliminary tests such as AC impedance (shown in Figure 4 on the right) and CV.

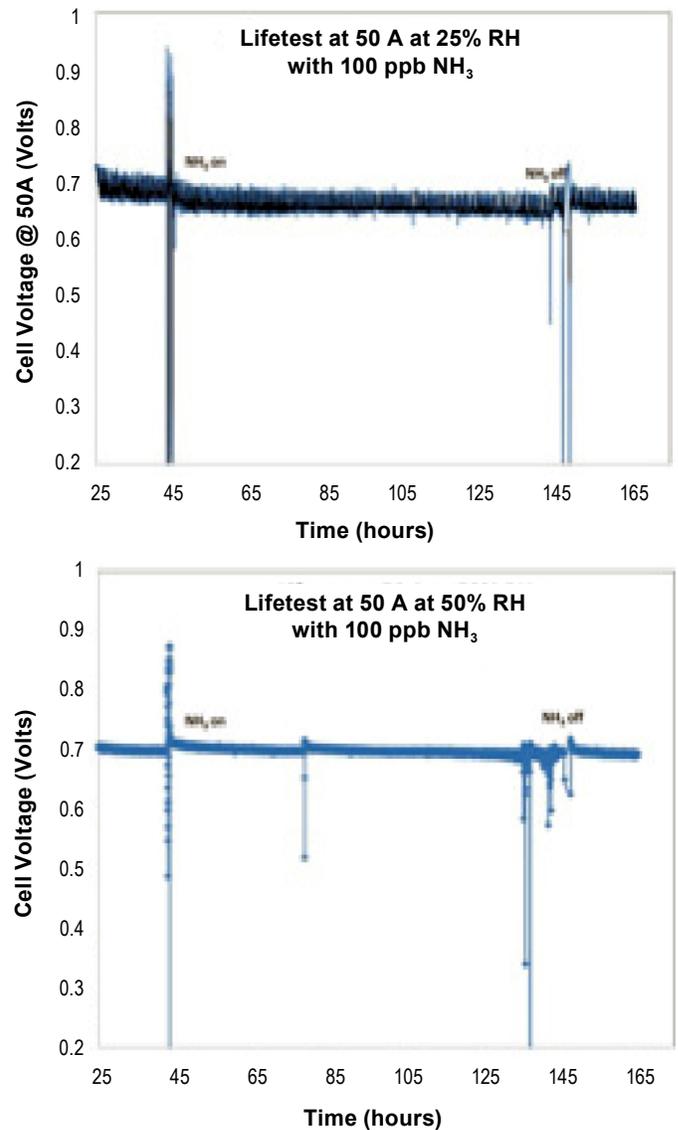

FIGURE 3. Cell voltage monitored before, during and after 100 ppb ammonia exposure at two different RHs for a fuel cell operating at 1 A/cm².

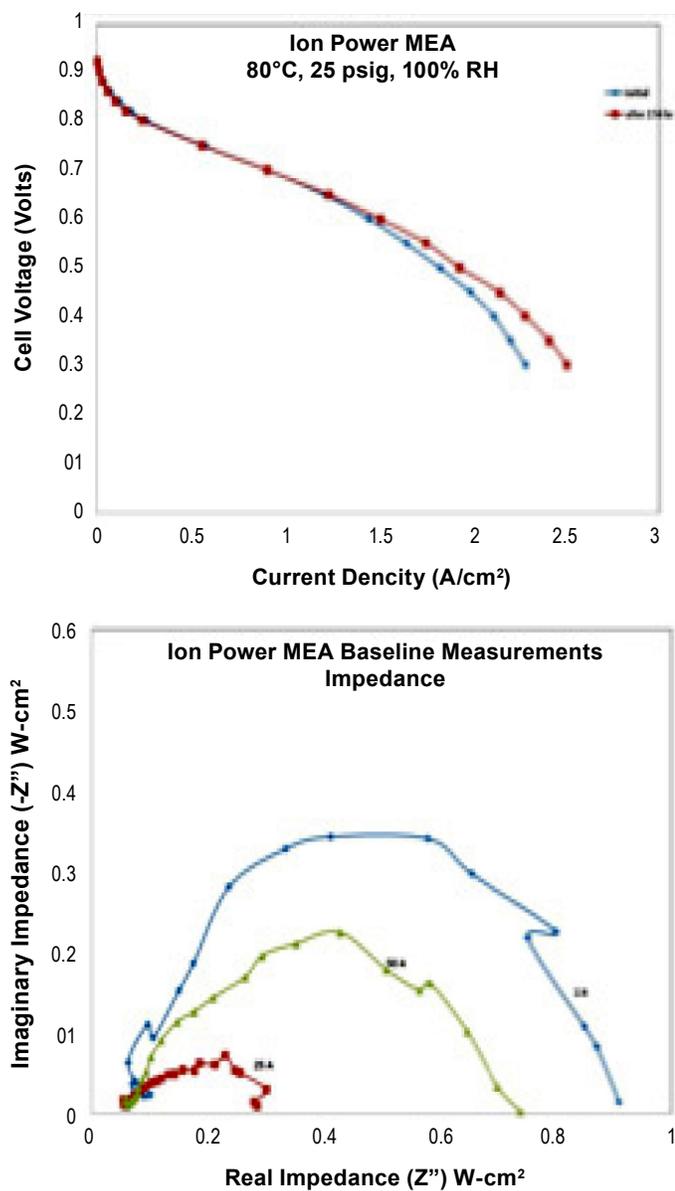

FIGURE 4. Initial tests results of Ion Power MEA (i.e. low loading) to probe durability concerns/issues.

Project Start Date: 2004

Project End Date: Project continuation and direction determined annually in consultation with DOE

Fiscal Year (FY) 2011 Objectives

- Provide expertise and recommendations to DOE and assist with identifying safety-related technical data gaps, best practices and lessons learned.
- Help DOE integrate safety planning into funded projects to ensure that all projects address and incorporate hydrogen and related safety practices.

Technical Barriers

This project addresses the following technical barriers from the Hydrogen Safety section (3.8) of the Fuel Cell Technologies (FCT) Program Multi-Year Research, Development and Demonstration Plan:

- (A) Limited Historical Database
- (B) Proprietary Data
- (C) Validity of Historical Data
- (D) Liability Issues

- (E) Variation in Standard Practice of Safety Assessments for Components and Energy Systems
- (F) Safety is Not Always Treated as a Continuous Process
- (G) Expense of Data Collection and Maintenance
- (H) Lack of Hydrogen Knowledge by Authorities Having Jurisdiction
- (I) Lack of Hydrogen Training Facilities for Emergency Responders

Contribution to Achievement of DOE Hydrogen Safety Milestones

This project contributes to achievement of the following DOE milestones from the Hydrogen Safety section of the Fuel Cell Technologies Program Multi-Year Research, Development and Demonstration Plan:

- **Milestone 8:** Complete investigation of safe refueling protocols for high pressure systems. (1Q, 2012)
- **Milestone 20:** Update peer-reviewed Best Practices Handbook. (4Q, 2008/ongoing)

Related milestones in Task 3 (Failure Modes), Task 5 (Safety of DOE R&D Projects), Task 6 (Hydrogen Safety and Incidents), Task 7 (Best Practices Handbook) and Task 8 (Hydrogen Safety Props) of the above reference have all been achieved with support from the Hydrogen Safety Panel.

FY 2011 Accomplishments

- Conducted Hydrogen Safety Panel meeting in Washington, D.C., April 7-8, 2010; planned Hydrogen Safety Panel meeting (September 11, 2011) in conjunction with the International Conference on Hydrogen Safety, San Francisco, CA.
- Reviewed 60 safety plans since July 1, 2010 for projects in fuel cell research and development (R&D) and American Recovery and Reinvestment Act (ARRA)-funded fuel cell deployments.
- Conducted safety review site visits for four FCT-funded projects; completed and submitted six safety evaluation reports; conducted three follow-up teleconferences for previously issued safety evaluation reports and submitted interview reports; published two issues of *H2 Safety Snapshot* (<http://www1.eere.energy.gov/hydrogenandfuelcells/codes/snapshot.html>).
- Provided technical guidance, source material and review for the Hydrogen Incident Reporting and Lessons Learned database (www.h2incidents.org) and Hydrogen Safety Best Practices (www.h2bestpractices.org).

Introduction

Safety is an essential element for realizing the “hydrogen economy” – safe operation in all of its aspects from hydrogen production through storage, distribution and use; from research, development and demonstration to commercialization. As such, safety is given paramount importance in all facets of the research, development, demonstration and deployment work of the DOE FCT Program Office.

Recognizing the nature of the DOE program and the importance of safety planning, the Hydrogen Safety Panel was formed in December 2003 to bring a broad cross-section of expertise from the industrial, government and academic sectors to help ensure the success of the program as a whole. The experience of the Panel resides in industrial hydrogen production and supply, hydrogen R&D and applications, process safety and engineering, materials technology, industrial liability and facility insurance, risk analysis, accident investigation and fire protection. The Panel provides expertise and recommendations on safety-related issues and technical data gaps, reviews individual DOE-supported projects and their safety plans and explores ways to bring best practices and lessons learned to broadly benefit the DOE program.

Approach

The Panel strives to raise safety consciousness most directly at the project level. Safety should be driven at the project level by organizational policies and procedures, safety culture and priority. Project safety plans are reviewed in order to encourage thorough and continuous attention to safety aspects of the specific work being conducted. Panel-conducted safety reviews focus on engagement, learning, knowledge-sharing and active discussion of safety practices and lessons learned, rather than as audits or regulatory exercises. Through this approach, DOE and the Hydrogen Safety Panel are trying to achieve safe operation, handling and use of hydrogen and hydrogen systems for all DOE projects.

Results

The Hydrogen Safety Panel was formed in FY 2004 and the first meeting was held in Washington, D.C., December 11-12, 2003. The 15th Panel meeting was held in Washington, D.C., April 7-8, 2011 and included two topical themes: (1) “incident owners” discussed what was learned from specific hydrogen safety events; (2) Panel work on ARRA-funded fuel cell deployment projects, including materials handling applications, was reviewed. Planning is in progress for the 16th meeting to be held in San Francisco, CA, September 11, 2011, in conjunction with the International Conference on Hydrogen Safety.

Current Panel membership is noted in Table 1.

TABLE 1. Hydrogen Safety Panel

Edward G. Skolnik, Technical Support	Energetics, Inc.

The Panel conducted safety reviews for projects as noted in Table 2 since the last reporting (safety reviews have been conducted for 45 projects since March 2004). Final reports issued to DOE with recommendations are also noted [1-6]. At the National Renewable Energy Laboratory’s invitation, a Panel team participated (September 21, 2010) in a 30% design review of a new facility, the Energy Systems Integration Facility.

In FY 2010, the Panel first established a follow-up protocol to interview project teams in order to identify actions, findings and conclusions regarding safety review recommendations as one means for measuring the value of this work. Action on report recommendations represents a rich source of safety knowledge that can have broader benefits to others. Table 2 identifies the follow-up interviews that were conducted since the last reporting [7-9] and Table 3 summarizes the conclusions for all follow-up interviews conducted to date.

The Panel concluded that all interviewees have improved the safety aspects of the work they are conducting. Overall, over 90% of the recommendations – 90 in number – have been implemented in some manner or are in progress for the 11 follow-up interviews conducted. The Panel has concluded that the mechanism used by the Panel for seamless discussion and knowledge sharing at the project level has helped augment the prime responsibility of any organization to ensure the safe conduct of work [10].

The Hydrogen Safety Panel contributes to PNNL’s ongoing work in updating and adding new technical content to two safety knowledge tools, the Hydrogen Safety

* Safety evaluation report for previously conducted site visit

Follow-up interview and report

Best Practices website (www.h2bestpractices.org) and the Hydrogen Incident Reporting and Lessons Learned database (www.h2incidents.org). For example, the Panel supported work on best practices to add new content on hydrogen properties, chemical hydrogen storage and indoor refueling of hydrogen-powered fuel cell forklifts. Panel members also assisted in reviewing technical content for the following postings in the Lessons Learned Corner of the above mentioned safety event database:

- The Importance of Purging Hydrogen Piping and Equipment
- Hydrogen Use in Anaerobic Chambers
- Adequate Ventilation of Battery Charging Facilities
- Learning from Burst Disk Failures

With Panel members serving as technical contributors and reviewers, two issues of the topical newsletter, *H2 Safety Snapshot*, were published:

- Handling Compressed Hydrogen Gas Cylinders [11]
- Identifying Safety Vulnerabilities [12]

Leadership has been provided to the International Energy Agency Hydrogen Implementing Agreement Task 31 (Hydrogen Safety) for the work under Subtask D, Knowledge Analysis, Dissemination and Use. The recently completed work under Task 19 (Hydrogen Safety) helped facilitate collaboration between member countries on the incident lessons learned and best practices databases [13].

Conclusions and Future Directions

Being conscious of the need to use safe practices is a necessary first step for the conduct of all work. The work and approaches taken by the Panel will continue to focus on how safety knowledge, best practices and lessons learned can be brought to bear on the safe conduct of project work.

The Panel will undertake a number of initiatives in FY 2012 including:

- Safety plan reviews, safety review site visits and a final report for ARRA fuel cell deployment projects in specialty vehicle, auxiliary and back-up power, portable and combined heat and power applications.
- Follow-up teleconferences with all project teams for which safety review site visit reports have been issued in order to identify actions taken, findings, conclusions and other learnings.

Total	56	34	8	98

- Technical support for work on future issues of *H2 Safety Snapshot* and PNNL's hydrogen safety knowledge databases.
- Additional topics for study consistent with the Hydrogen Safety Panel's charter to identify safety-related data and knowledge gaps.

The 17th and 18th meetings of the Hydrogen Safety Panel are planned for April 2012 and September 2012, respectively.

Project Start Date: March 2003
Project End Date: Project continuation and
direction determined annually by DOE

- **Milestone 20:** Update peer-reviewed Best Practices Handbook (4Q, 2008).

FY 2011 Accomplishments

Hydrogen Safety Best Practices

- Added a new section on Hydrogen Properties, which is focused on combustion and liquid hydrogen expansion.
- Added a new section for students, technicians, and young engineers less familiar with hydrogen called “So You Want to Know Something about Hydrogen.”
- Added a new section on Indoor Refueling of Hydrogen-Powered Forklifts with assistance from a team of industry experts.
- Added a new section on Chemical Hydrogen Storage.
- Added more photos to enhance the website appearance.

Hydrogen Incident Reporting and Lessons Learned

- Added 56 new safety event records from national laboratories, universities, and private-sector firms in the U.S. and other countries since the 2010 Annual Merit Review (AMR), for a total of 195 records currently in the database.
- Created quarterly postings of the Lessons Learned Corner to analyze and present hydrogen safety themes illustrated with database content.

Fiscal Year (FY) 2011 Objectives

- Hydrogen Safety Best Practices - Capture the vast knowledge base of hydrogen experience and make it publicly available. The best practices online manual is a “living” document that provides guidance for ensuring safety in DOE hydrogen projects, while serving as a model for all hydrogen projects and applications.
- Hydrogen Incident Reporting and Lessons Learned - Collect information and share lessons learned from hydrogen incidents and near-misses, with the goal of preventing similar safety events from occurring in the future.

Technical Barriers

This project addresses the following technical barriers from the Hydrogen Safety section of the Fuel Cell Technologies (FCT) Program Multi-Year Research, Development and Demonstration Plan:

- (A) Limited Historical Database
- (B) Proprietary Data

Contribution to Achievement of DOE Safety, Codes & Standards Milestones

This project has already met the following DOE milestones from the Hydrogen Safety section of the FCT Program Multi-Year Research, Development and Demonstration Plan:

- **Milestone 18:** Publish safety bibliography and incident databases (3Q, 2006).
- **Milestone 19:** Publish a Best Practices Handbook (1Q, 2008).

Introduction

PNNL has developed and continues to improve two software tools to support the Hydrogen Safety, Codes and Standards sub-program. This report covers the Hydrogen Safety Best Practices online manual (<http://www.H2BestPractices.org>) and the Hydrogen Incident Reporting and Lessons Learned database (<http://www.H2Incidents.org>). The National Research Council’s second report on the FreedomCAR and Fuel Partnership states that “The creation of a database on incidents involving hydrogen will be useful in promoting safety” [1]. The report also states that “The committee encourages DOE to continue to develop, publish, and update the best practices document.”

Approach

Hydrogen Safety Best Practices - There are many references and resources that deal with the safe use of hydrogen, and our intent is to organize and compile relevant information in an easy-to-use Web-based manual without

duplicating existing resources. PNNL teams with the Hydrogen Safety Panel, other national laboratory staff, and other subject matter experts to compile hydrogen-specific best practices from a variety of references. Links to Web-based resources and files are provided on the website.

Hydrogen Incident Reporting and Lessons Learned

- The purpose of “H2Incidents.org” is to facilitate open sharing of lessons learned from hydrogen safety events to help avoid similar incidents in the future. Our approach includes encouraging DOE-funded project teams and others to voluntarily submit incidents and near-misses and to provide specific lessons learned. We continue to pursue the addition of new records by actively seeking news reports on hydrogen incidents and searching existing databases and other sources for hydrogen-related safety event records. We contact private-sector companies who experience hydrogen-related safety events to solicit their permission to publish such records. We continue to maintain a mechanism for online submission of records. Specific safety event records are linked to Best Practices online manual content to emphasize safe practices for working with hydrogen and avoiding future incidents. Expert review of all safety events and lessons learned is provided by PNNL subject matter experts and the Hydrogen Safety Panel.

Results

Hydrogen Safety Best Practices – Existing content was supplemented with four new sections, and we added a number of photos to enhance the website appearance. A new section on Hydrogen Properties was added, which is focused on combustion and liquid hydrogen expansion. This section was developed collaboratively with members of the Hydrogen Safety Panel and the National Aeronautics and Space Administration White Sands Test Facility.

To serve the needs of students, technicians, and young engineers less familiar with hydrogen, a new section was added called “So You Want to Know Something about Hydrogen.” The new section discusses properties and behavior, applications, and systems and controls, and a subsection on Hydrogen Hazards covers leaks, flames, and explosions. The Hydrogen Hazards section is not intended to dissuade anyone from working with hydrogen, but to make them aware that constant vigilance is necessary when working with or around hydrogen. In fact, hydrogen is just as safe as gasoline or any other commonly used fuel, it’s just different. If you understand the differences, you will understand how to work safely with hydrogen.

Another new section on Indoor Refueling of Hydrogen-Powered Forklifts was developed with a team of subject matter experts from Air Products and Chemicals, Nuvera Fuel Cells, the National Renewable Energy Laboratory, and PNNL. This section covers design considerations, piping safeguards, leak mitigation, vehicle safety features, operations, and training.

A new section on Chemical Hydrogen Storage complements the existing material on Metal Hydride Storage and Handling. The term “chemical hydrogen storage” is used to describe storage technologies in which hydrogen is released and then later restored through chemical reactions. Many of the compounds that are being investigated for chemical hydrogen storage have never been synthesized, so material safety data sheets do not exist. Chemical hydrides present special hazards, including toxic byproducts, water and air reactivity, pyrophoricity, potential for runaway reactions with gas formation, and room-temperature gas emissions and instabilities.

Hydrogen Incident Reporting and Lessons Learned

- We added 56 new incident records since the 2010 AMR. These records came from national laboratories, universities, and private-sector firms in the U.S. and other countries. We currently have 195 records in the database, with at least 30 more in progress. Most incident alerts were obtained from DOE or Google Alerts for hydrogen and fuel cell vehicles. Significant time was spent interacting with incident “owners” to encourage them to submit records of incidents and near-misses. We also posted quarterly installments of the Lessons Learned Corner to analyze hydrogen safety themes illustrated by database content.

We incorporated bar graphs to characterize the database contents in terms of settings, equipment, damage/injuries, probable causes, and contributing factors. The visual display makes it clear that the content is dominated by laboratory incidents (almost as many incidents as the next four highest settings combined).

Last year, we created a Lessons Learned Corner (LLC) to analyze the database content. We publish the LLC quarterly based on a specific theme that is illustrated with safety event records in the database. Themes covered to date include:

- Management of Change
- Working with Reactive Metal-Hydrides
- The Importance of Purging Hydrogen Piping and Equipment
- Hydrogen Use in Anaerobic Chambers
- Adequate Ventilation of Battery Charging Facilities
- Learning from Burst Disk Failures.

As an example, the basic theme of the LLC on The Importance of Purging Hydrogen Piping and Equipment is that all personnel should be trained on proper procedures for taking hydrogen systems offline and bringing them back online. Hydrogen Safety Panel members utilized their significant industrial experience to assist us in extracting clear lessons learned about purging systems. When getting ready for maintenance, you should always be conservative and assume that hydrogen is present and use a properly vented inert gas subsystem for purging. Likewise, when bringing a hydrogen system back online, you should always

assume that air is present and reduce oxygen levels below 1% before putting the system back online. Three very diverse incidents that were caused by improper purging are highlighted in the LLC – one from a power plant setting, one from a hydrogen production facility, and one that occurred in a laboratory. In each incident, standard operating procedures related to system purging were ignored or altered, without thorough consideration of the potential consequences. Hydrogen was ignited in all three incidents, and serious explosions could have occurred if larger volumes of hydrogen had been in use.

Conclusions and Future Directions

Hydrogen Safety Best Practices - Our future work includes improving existing website content as well as drafting new content. Ideas for new content come from the Hydrogen Safety Panel, other national laboratories, technical reviewers at the DOE AMR, and actual website users. We are planning a brainstorming session with the Hydrogen Safety Panel to identify any gaps in website content that should be addressed.

PNNL continues to monitor website usage and respond to user feedback. Users have submitted many requests for additional information and guidance through the website's comment submittal feature. We routinely seek guidance from one or more Hydrogen Safety Panel members in crafting our responses to these requests. Website utility is enhanced by continuing to link the content to safety event records in the Hydrogen Incident Reporting and Lessons Learned database and by adding photos, graphics, and videos to complement the text.

Hydrogen Incident Reporting and Lessons Learned - Our future work will focus on increasing the number of records in the database, in part through identifying additional sources of hydrogen safety event data and lessons learned. A significant part of our effort involves working with the national laboratories, universities, and private-sector firms that experience hydrogen incidents and/or near-misses to help them communicate what happened, what the probable causes and contributing factors were, and most importantly, what lessons were learned by their organizations that could benefit others if they were freely shared. We will continue to monitor website usage and respond to user feedback.

We will also continue to encourage all DOE-funded projects, universities, private-sector organizations, and others to voluntarily submit records of their hydrogen incidents and near-misses. Success requires that people use the database and submit information without fear of negative consequences from reporting and publicizing safety events. We will continue to maintain confidentiality for the organizations that voluntarily submit safety event records.

Subcontractors:

- Jennifer Hamilton, California Fuel Cell Partnership (CaFCP), Sacramento, CA
- Hanford Fire Department, Richland, WA
- Hazardous Materials Management and Emergency Response (HAMMER) Training and Education Center, Richland, WA

Project Start Date: October 2004
Project End Date: Project continuation and direction determined annually in consultations with DOE

- (C) Disconnect Between Hydrogen Information and Dissemination Networks (ED)
- (D) Lack of Educated Trainers and Training Opportunities (ED)
- (H) Lack of Hydrogen Knowledge by Authorities Having Jurisdiction (SAF)
- (I) Lack of Hydrogen Training Facilities for Emergency Responders (SAF)

Contribution to Achievement of DOE Hydrogen Safety/Education Milestones

This project will contribute to achievement of the following DOE milestones from the Hydrogen Safety and Education sections of the Fuel Cell Technologies Program Multi-Year Research, Development and Demonstration Plan:

- Milestone 6 (ED): Update “prop-course” for first responders. (4Q, 2011)
- Milestone 7 (ED): Update “Awareness-Level” information package for first responders. (4Q, 2012)
- Milestone 9 (ED): Update “prop-course” for first responders. (4Q, 2014)
- Milestone 10 (ED): Update “Awareness-Level” information package for first responders. (4Q, 2015).

In addition, the following milestones were met in previous years:

- Milestone 1 (ED): Develop “Awareness-Level” information package for first responders. (4Q, 2006)
- Milestone 3 (ED): Develop “prop-course” using hands-on training devices for first responders. (4Q, 2008)
- Milestone 4 (ED): Update “Awareness-Level” information package for first responders. (4Q, 2009).
- Milestone 21 (SAF): Conduct first hydrogen safety class (non-prop) offered at HAMMER. (3Q, 2005)
- Milestone 22 (SAF): Complete first life-size prop for hands-on training of emergency responders. (1Q, 2008).

Fiscal Year (FY) 2011 Objectives

- Support the successful demonstration and deployment of hydrogen and fuel cell technologies by providing technically accurate hydrogen safety and emergency response information to first responders.
- Provide a one-day first responder training course, “Hydrogen Emergency Response Training for First Responders,” that integrates the use of DOE’s mobile hydrogen fuel cell vehicle (FCV) prop.
- Continue to support the Web-based awareness-level course, “Introduction to Hydrogen Safety for First Responders.” www.hydrogen.energy.gov/firstresponders
- Disseminate first responder hydrogen safety educational materials at appropriate fire fighter conferences to raise awareness.

Technical Barriers

This project addresses the following technical barriers from both the Hydrogen Safety (SAF) and Education (ED) sections (3.8 and 3.9, respectively) of the Fuel Cell Technologies Program Multi-Year Research, Development and Demonstration Plan:

- (A) Lack of Readily Available, Objective, and Technically Accurate Information (ED)

FY 2011 Accomplishments

Prop-Based Course: This operations-level course was presented at several fire training centers throughout California in the past year. Three consecutive one-day training classes were held at each of the following locations:

- Rio Hondo College Fire Academy, Santa Fe Springs, CA (Aug 2010)
- Orange County Fire Authority, Irvine, CA (Aug 2010)
- Sunnyvale Dept. of Public Safety, Sunnyvale, CA (Sept 2010)

- San Joaquin Defense Logistics Agency (DLA), Tracy Site (June 2011)
- San Joaquin DLA, Sharpe Site (June 2011).

The last two noted DLA sites are military depots expecting installations of hydrogen fueling stations and hydrogen fuel cell-powered forklifts later this year. Therefore, the course material was updated this year to include additional information on the growing use of hydrogen fuel cell-powered industrial lift trucks (forklifts), and related emergency response information. Approximately 350 first responders from the above sites received this training. Extremely positive feedback from each of the sites continues to reinforce the value of this course to first responder organizations.

In October 2010, PNNL hosted a visit by the FreedomCAR directors and USCAR representatives. During their visit, attendees were given a demonstration of how the FCV prop is used for first responder training.

The Fire Department News Network produced a video of portions of the operations-level course during delivery of the course at Orange County Fire Authority in August 2010. The video was first aired on their website (www.fdnntv.com) in November 2010.

Awareness-Level Course: Our website still averages ~300 unique visits per month from almost every state and some foreign countries. The course is registered on the TRAIN (TrainingFinder Realtime Affiliate Network) website for broader dissemination to first responders. TRAIN is a central repository for public health training courses. Almost 30,000 TRAIN users identify themselves as emergency responders.

Outreach: Compact disks of the awareness-level course were distributed through the DOE Energy Efficiency and Renewable Energy Information Center. PNNL and HAMMER hosted a booth at a first responder conference (Fire Rescue International 2010) in Chicago, IL, August 2010.

Introduction

Safety in all aspects of a future hydrogen infrastructure is a top priority, and safety concerns influence all DOE hydrogen and fuel cell projects. Despite the most concerted effort, however, no energy system can be made 100% risk-free. Therefore, for any fuel and energy system, a suitably trained emergency response force is an essential component of a viable infrastructure. The Fuel Cell Technologies Program has identified training of emergency response personnel as a high priority, not only because these personnel need to understand how to respond to a hydrogen incident, but also because firefighters and other emergency responders are influential in their communities and can be a

positive force in the introduction of hydrogen and fuel cells into local markets.

This project employs the Occupational Safety and Health Administration and National Fire Protection Association frameworks for hazardous materials emergency response training to provide a tiered hydrogen safety education program for emergency responders. The effort started with development and distribution of the awareness-level Web-based course in FY 2006-2007. A more advanced course and materials to facilitate education were developed in FY 2008-2009, complementing the design, construction, and operation of a fuel cell vehicle prop (developed under PNNL's Hydrogen Safety project). The overall first-responder education program will continue to be updated. In addition, PNNL has implemented outreach efforts to key stakeholder groups to facilitate delivery of the training to a broad audience.

Approach

PNNL works with subject matter experts in hydrogen safety and first responder training to develop hydrogen safety course materials. Draft materials undergo considerable review and revision before being released. The PNNL team works with DOE to make stakeholder groups aware of training opportunities and to provide “live” training when appropriate. The Web-based awareness-level course is available “online” or on compact disks and provides the student with a basic understanding of hydrogen properties, uses, and appropriate emergency response actions. The prop-based course, a more advanced operations-level course, was initially presented at the HAMMER training facility in Richland, WA. Subsequently, the mobile prop has enabled the course to be delivered at several offsite fire training centers (in California during 2010-11) in order to reach larger audiences in areas where hydrogen and fuel cell technologies are being deployed.

Results

Prop-Based Course: The focus of the curriculum is on teaching first responders what is the same and what is different about hydrogen and FCVs as compared to conventional fuels and vehicles. Course evaluation forms are distributed and feedback obtained at each class to help us improve the course content and delivery. Based on feedback from all the class sessions held this past year (August 2010, September 2010, and June 2011), we conclude that following the training, first responders are more familiar with the properties and behavior of hydrogen, and are prepared to operate in a safe and effective manner if a hydrogen incident should occur in their jurisdiction.

The FCV prop has been integrated into the “Hydrogen Emergency Response Training for First Responders” course. The prop (shown in Figure 1) demonstrates potential conditions that could be encountered during the control

FIGURE 1. A Team of Fire Fighters Rescues a “Victim” from the Live-Fire Hydrogen FCV Prop

and suppression of a FCV fire. The photo shows a team of firefighters training to respond to a motor vehicle accident, in this case a multi-vehicle accident involving a hydrogen FCV and a conventional vehicle.

Conclusions and Future Directions

The introductory Web-based course has been quite successful, based on the usage recorded and feedback received. The course is fulfilling a need expressed by the first responder community to receive more information about hydrogen and fuel cells so they will be prepared in the rare event of a hydrogen incident. The in-depth prop-based course builds on that success and is very useful in giving first responders a hands-on experience with simulated FCV incidents that integrates well with classroom training. PNNL will continue to update both courses as needed to reflect current applications and markets for hydrogen and fuel cells.

There is an identified need for the prop course curriculum to achieve a better balance between the vehicles

and stationary facilities modules, through the development of some type of prop for stationary applications of fuel cells. An interactive video training tool of virtual hydrogen incident scenarios and responses to simulate both outdoor fueling of passenger FCVs and indoor fueling of hydrogen forklifts could address that need. We propose to develop a virtual model by first demonstrating the concept with a simplified model, and subsequently adding additional features and capabilities.

The prop course will be offered at additional first responder training facilities in California in FY 2012. As additional hydrogen fueling stations are commissioned and more FCVs appear on the road, more first responder organizations are inquiring about this training. As with the previous training classes, the prop will be transported to California in its trailer and left at each site for about a week. Multiple classes will be offered at each site. In future years, the prop will be transported to other locations across the country for use in delivery of this course at training centers in areas that have emerging deployments of hydrogen and fuel cell technologies. PNNL will also work with DOE and other stakeholders to determine what, if any, additional types of educational courses and materials are warranted, and to develop and implement plans to provide education to specific groups.

Project Start Date: October 2008
Project End Date: Project continuation and
direction determined annually by DOE

- Acquired Web domain www.h2labsafety.org for intuitive, easy to remember access.
- Registered 100+ Web class completions.
- Procured materials and equipment for hands-on class.
- Completed lesson plan for hands-on class.

Introduction

LLNL has been conducting hydrogen research for more than 50 years, starting with national security applications and continuing with energy research. For many of these years, LLNL was designated as the pressure safety training facility for the whole DOE complex and other government institutions such as the National Aeronautics and Space Administration. Many technicians and researchers visited LLNL to receive training on many aspects of pressure safety, including hydrogen technology, cryogenics, leak detection, and vacuum technology.

The national security hydrogen and high-pressure research conducted at LLNL demanded unique testing facilities, and these were built with funding from DOE National Nuclear Security Administration. These facilities include a high pressure laboratory equipped with four hydrogen-compatible test cells, each rated for 80,000 psi, and 4 pounds of trinitrotoluene (TNT) equivalent stored energy. LLNL also has a high explosive test facility (Site 300) for experiments with many pounds of TNT equivalent and many kg H₂. Experiments at Site 300 are typically conducted in outdoor firing tables and monitored from the safety of a bunker. The remote location of this facility protects employees and property from any hazard.

These unique facilities and the expertise necessary to operate them are now being made available for hydrogen energy research through the development of training materials that may contribute to safe operation within the many institutions working on hydrogen technology.

Approach

We are pursuing a two-pronged approach to hydrogen safety training:

- Researchers conducting laboratory experiments can benefit from basic training on hydrogen and pressure safety. This Web-based training can be completed in ~4 hours.
- Technical personnel in charge of setting up experimental equipment require comprehensive hands-on training on all aspects of hydrogen systems. This extensive training is planned for three full days.

Fiscal Year (FY) 2011 Objectives

- Prepare safety training materials for researchers running H₂ laboratory experiments.
- Prepare advanced safety training materials for personnel in charge of hydrogen systems.

Technical Barriers

This project addresses the following technical barriers from the Hydrogen Safety section (3.8) of the Fuel Cell Technologies Program Multi-Year Research, Development and Demonstration Plan:

- (H) Lack of Hydrogen Knowledge by Authorities Having Jurisdiction
- (I) Lack of Hydrogen Training Facilities

Contribution to Achievement of DOE Hydrogen Safety, Codes & Standards Milestones

This project will contribute to achievement of the following DOE milestones from the Hydrogen Safety section of the Fuel Cell Technologies Program Multi-Year Research, Development and Demonstration Plan:

- **Milestone 17:** Identify user needs for basic safety information

FY 2011 Accomplishments

- Released a final version of the Web-based "Hydrogen Safety Class for Researchers"

Results

The Web-based hydrogen safety class (www.h2labsafety.org) was publicly released in September of 2010. Since then we have registered over 100 completions from universities, government institutions, and private companies from five countries (USA, Canada, United Kingdom, Japan, and Mexico). Before public release, class materials were thoroughly reviewed by a panel of safety experts through two rounds of peer review, focusing on the technical aspects as well as on the teaching aspects of the class. Further improvement is always possible, however, and we therefore invite readers to take the class and submit comments to the authors that may improve the learning experience, update the class information, and/or report bugs or malfunctions. Class authors can be contacted by e-mail at any time during the course, by clicking on the “help” button in the top menu (or use author’s e-mail address listed above).

In addition to the Web-based fundamentals class, we are developing a hands-on hydrogen safety class for pressure operators. This comprehensive training includes basic hydrogen safety, regulators, relief devices, leak detection, and flash arrestors, followed by hands-on assembly and test of a hydrogen pressure system and a final evaluation. Training can be conducted during a three-day session at LLNL, or at remote institutions if appropriate facilities (classroom, compressed gas supply, and pressure testing laboratory) exist.

The hands-on training class starts with a full day of classroom instruction covering essential topics of pressure system assembly and operation (Table 1). Classroom instruction focuses on identifying hazards, safety precautions, personal protective equipment, and pressurized hydrogen system components and their function. This class greatly expands the descriptions from the Web-based hydrogen safety class, going into detailed operational information about every component in pressure systems, describing their inner functionality, applicability, and recommended use. Teaching is aided by segmented components that reveal their inner operational details (Figure 1). At the end of classroom instruction, students will be able to identify (i) the main hydrogen pressure system components, (ii) pressure and hydrogen based hazards, (iii) the types of personal protective equipment that are used for pressurized hydrogen systems, and (iv) the pressurized hydrogen system component categories and their functions. In the final activity of the day, students are tested on the class materials.

Days two and three will be spent in the laboratory for practical application of the classroom information from day one. On day two, students will be handed a safety document and instructed to assemble the pressure system described therein (Figure 2). Students will have to select, inspect and install pressure components, bend tube, install pipe and compression fittings, and assemble the entire system.

On day three this system will be leak checked with a mass spectrometer helium leak detector with a leak rate of no more than 1.0×10^{-5} atm-cc/sec helium. The pressure

TABLE 1. Hands-On Safety Class Structure

Modules	
Day 1	Classroom Teaching
	<ol style="list-style-type: none"> 1. Definitions 2. Hazards 3. Personal Protective Equipment 4. Gas Cylinders 5. Gas Cylinder Manifold 6. Pressure Reducing Regulators 7. Gauges/Pressure Transducers 8. Regulator Safety Manifold 9. Relief Devices 10. Valves 11. Fittings 12. Tubing and Piping 13. Flash Arrestors 14. Quiz
Day 2	Pressure system assembly
	Given a system schematic and description, select components, inspect and install, cut and bend tube, apply various fittings, and assemble full system
Day 3	System leak test and operation
	Leak test using a mass spectrometer leak detector; setup data acquisition; conduct remote pressure test; leak test at maximum operating pressure using leak detection fluid; operate system to reach a desired pressure

system will then be connected to the data acquisition system and pressure tested remotely at 150% of the maximum allowable working pressure. The last leak test will be conducted using liquid leak detection fluid at the system’s maximum operating pressure. Finally, the students will operate the system to reach a desired pressure.

During the two days of laboratory work, students will be tested as they build and test the system. On day two, tests will focus on correct system assembly (select appropriate components, inspect them, install them in the right place, bend tubing correctly, install plumbing at the correct place, and install pipe and compression fittings). On day three, students will be tested during leak checks and necessary system rebuilds to meet the leak test criterion. At the end of day three, based on the successful completion and testing of the assembled panel, students will be awarded a Certificate of Completion for “LLNL Hands-On Hydrogen Safety Training”.

The hands-on class is still under development. Two working benches and instructional materials including segmented pressure components (regulators, valves, gauges, Figure 1) have been prepared as teaching materials to best instruct component function. Classroom instruction materials are being prepared.

Conclusions and Future Directions

LLNL is contributing to safe hydrogen operations by developing instructional materials for researchers and technical operators:

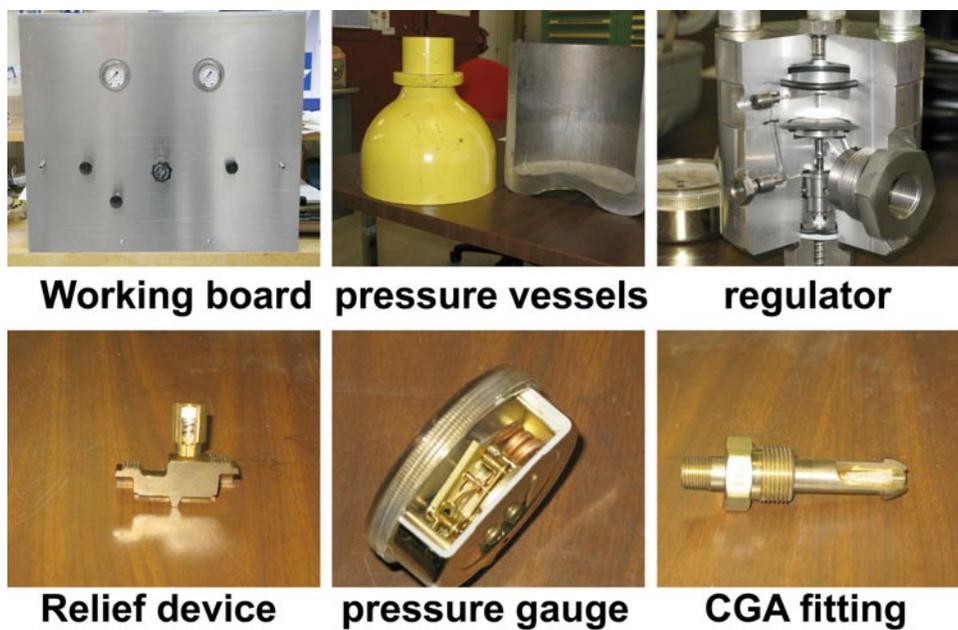

FIGURE 1. Working board and different pressure components segmented to illustrate internal structure and operability.

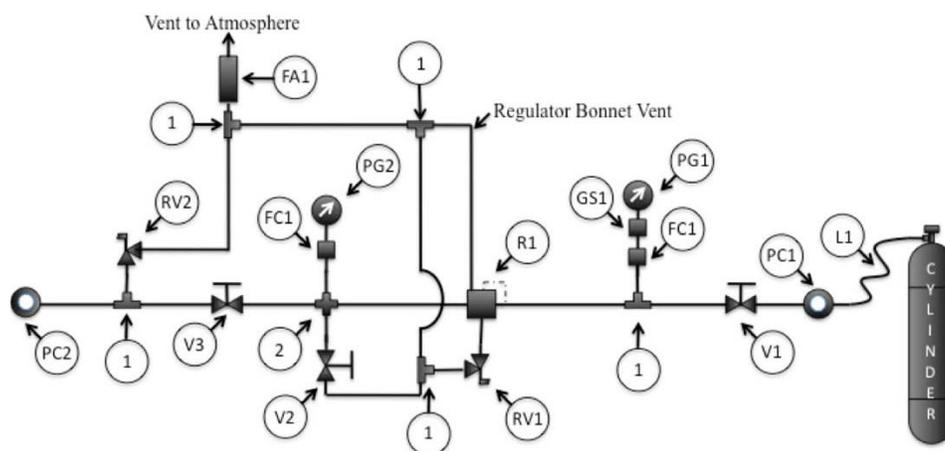

FIGURE 2. Piping and instrumentation diagram for the pressure system to be assembled during the hands-on hydrogen safety class.

- *Laboratory researchers* can obtain basic hydrogen safety information from a 4-hour Web-based class (free online access at <http://www.h2labsafety.org/>) addressing hydrogen fundamentals: properties, pressure and cryogenic safety, emergency response and codes and standards.
- *Technical operators* in charge of building and testing experimental hydrogen equipment require more in-depth information than provided by the Web-based class. We are therefore preparing a 3-day hands-on safety class that presents detailed information for installation, testing, and operation of hydrogen pressurized systems. The hands-on class includes a full day of classroom instruction followed by two days

of laboratory work where students assemble, test and operate a pressure system based on a schematic and component description.

We strongly encourage participation of the members of the hydrogen community to improve the technical and educational aspects of the class by providing feedback and comments.

Contract Number: DE-FG36-08G088098

Project Start Date: June 1, 2008

Project End Date: November 30, 2011

- **Delivery: Barrier I. Hydrogen Leakage and Sensors** (MYRDDP page 3.2-20: “Low cost hydrogen leak detector sensors are needed”)
- **Storage: Barrier H. Balance of Plant (BOP) Components** (MYRDDP page 3.3-14: “Light-weight, cost-effective... components are needed...These include... sensors”)
- **Manufacturing R&D: Barrier F. Low Levels of Quality Control and Inflexible Processes** (MYRDDP page 3.5-11: “Leak detectors... are needed for assembly of fuel cell power plants.”)
- **Technology Validation: Barrier C. Lack of Hydrogen Refueling Infrastructure Performance and Availability Data** (MYRDDP page 3.6-8: “...the challenge of providing safe systems including low-cost, durable sensors [is an] early market penetration barrier”)

This project will contribute to the achievement of the following DOE milestones from the Hydrogen Safety/Leak Detection Technology section of the Fuel Cell Technologies Program Multi-Year Research, Development and Demonstration Plan:

- MYRDDP Milestone: Develop sensors meeting technical targets. (4Q, 2012)
- MYRDDP Milestone: Develop leak detection devices for pipeline systems. (4Q, 2015)

Overall Objectives

- Integrate hydrogen indicator chemistry into a complete optoelectronics package with well-defined sensing characteristics and a known end-use market.
- Develop signal processing and user interface software/firmware to assure sensor meets appropriate standards for commercial acceptance.

Fiscal Year (FY) 2011 Objectives

- Select and finalize hydrogen sensor components and outline scalable cost analysis.
- Finalize sensor data processing algorithms with minimum false alarms.
- Fabricate, test, and validate performance of 14 fully packaged prototypes.
- Deploy prototypes at four different field test sites.
- Collect and analyze real-time test data under various deployment conditions.
- Reach end-users through field demonstrations and field trails.

Technical Barriers

This project addresses the following technical barriers from several sections of the Fuel Cell Technologies Program Multi-Year Research, Development and Demonstration Plan (MYRDDP):

FY 2011 Accomplishments

The hydrogen safety sensor being developed in this project has advanced from the applied research stage (DOE technology readiness level, TRL, 3) to the engineering prototype (TRL 6) stage. Initial work focused on exploring a family of colorimetric hydrogen sensor formulations and physical embodiments for different venues and markets. These included porous glass “optrodes,” polymer integrated optic chip sensors, and hydrogen-sensitive optical fibers many meters in length (Figure 1). Economic and regulatory considerations led to the selection of an optrode-based handheld/wall-mounted format for the engineering prototypes. Key accomplishments during the past year include:

- Hydrogen safety sensor prototype refined/ruggedized.
- Optrodes have high sensitivity and rapid hydrogen response.
- Sensor repeatability/reversibility validated in third-party (National Renewable Energy Laboratory, NREL) tests.
- Hydrogen alarm algorithm developed and validated in field tests.
- Potential for high-accuracy concentration measurement demonstrated.

Introduction

Assuring safety is critically important to fostering commercial acceptance of hydrogen energy technologies, and to sustaining the use of hydrogen as a green energy source. A key to maintaining safety in hydrogen vehicles and installations is the ability to detect and warn of potentially hazardous conditions.

The overarching goal of this project is to create a reliable, cost-effective, alarm that warns of hydrogen leaks before they reach flammable concentrations. In the course of meeting this goal, we have demonstrated a proprietary hydrogen indicator chemistry that can be deployed in variety of optical formats, suitable for applications ranging from wide-area monitoring to point detection. Under DOE guidance, we have integrated a miniaturized indicator-bearing optical transducer with optoelectronic hardware and advanced signal processing software into a compact “smoke-detector-style” unit that will meet DOE- and customer-specified goals for sensitivity, response time, and reliability. This safety sensor will find use in many environments, including fuel cell-powered industrial vehicles, stationary power units, hydrogen generation and refueling stations, and storage locations.

Approach

- The hydrogen alarm sensor uses an optoelectronic platform (Figure 2) to monitor a porous glass sensor element (“optrode”) hosting a colorimetric indicator. Upon hydrogen exposure, the optrode changes color, and the sensor unit uses the resulting optical signal to calculate hydrogen concentration. A second porous glass element, not containing the hydrogen indicator, gives the sensor an “internal reference” that minimizes environmentally induced false alarms (Figure 1).
- IOS’ hydrogen sensor approach is unique in many aspects. First, each sensor unit uses an intrinsically safe low-power sensing element that functions without the heat required by many electronic hydrogen sensors. The unit employs another porous glass element, not containing the hydrogen indicator, gives the sensor an “internal reference” to minimize environmentally induced false alarms. Second, the unit has a faster response time and higher sensitivity levels, over a wider range of environmental conditions (i.e., temperature and humidity), than most of its counterparts. The sensor module can also be cabled to a readout unit for remote monitoring applications.

Results

In preparation for construction and delivery of 14 hydrogen sensor alarms for field testing, several elements

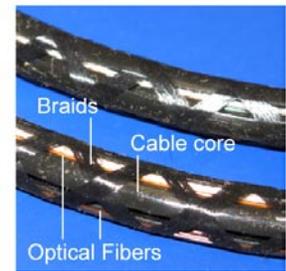

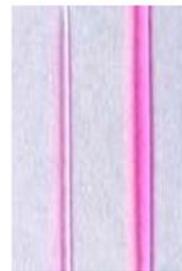

FIGURE 1. Optical Hydrogen Sensor Formats Top: optrodes in prototype mount; Bottom Left: integrated optic polymer waveguides; Bottom Right: extended-length sensor cable.

FIGURE 2. Compact Hydrogen Safety Sensor Unit

of the second-generation compact sensor were upgraded. Most notably, “noise” and “drift” in optical signals has been significantly reduced by redesigning the quick-connect optrode holder (Figure 1, top) to improve optical coupling between sensor elements and optoelectronic components. Changes in printed wiring board design were also implemented to simplify construction and address issues uncovered during testing of earlier versions. The result is a fully finalized physical and electronic design. All components have been procured, and construction of the field-test prototype units has begun. We project a mass-produced unit sale price of \$100-\$400, depending on features.

Sensor element materials and processing have also been finalized; a fabrication procedure has been selected that reproducibly generates optrodes of uniformly high quality. These transducers can respond to hydrogen at very low concentrations (Figure 3, top), and have been used to implement a high-speed alarm algorithm (Figure 3, bottom). Alarm response times are shown in Table 1. For all hydrogen concentrations at or above 10% of the lower flammability limit, (4% H₂ in air), the hydrogen leak detector sounds an alarm in less than 5 seconds.

TABLE 1. Hydrogen Alarm Response Times

H ₂ (%)	Detection Time (s)*
4.0	3
2.0	3
1.0	3
0.5	3
0.1	10
0.05	10
0.02	30
0.01	120

Determinations of sensor response and alarm algorithm function carried out at IOS have been independently verified in third-party tests carried out at NREL. Measurements of optrode signal sensitivity (Figure 4), repeatability, and reversibility (lack of hysteresis), have produced identical results to within the precision of the measurement apparatus. Multiple exposures to hydrogen release at NREL also showed the robustness of the rapid-response alarm algorithm (Figure 5). Preliminary tests of sensor response to simulated real-world leaks were carried out during a controlled release of hydrogen into a building at Sandia National Laboratories’ Livermore facility. Optrode response closely tracked the hydrogen concentration in the building (Figure 6), verifying the feasibility of using optrodes not only for the development of safety alarms, but in high-accuracy hydrogen concentration sensors as well.

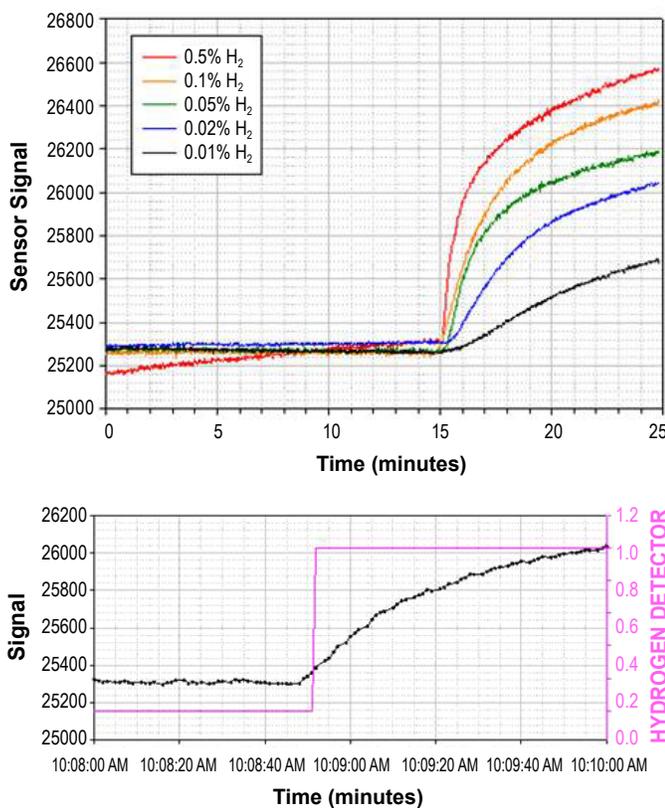

FIGURE 3. Rapid Response and High Sensitivity Top: response to low concentrations of hydrogen (0.01% H₂ = 0.25% of lower flammability limit; 0.5% H₂ = 12.5% lower flammability limit); Bottom: alarm algorithm (red line) triggers rapidly as optrode responds (black line) to 0.4% H₂ (10% lower flammability limit).

Conclusions and Future Directions

The prototype hydrogen leak alarm design is complete, and incorporates several upgrades based on results from IOS, NREL, and Sandia National Laboratories tests of earlier test units. Preliminary verification of the alarm

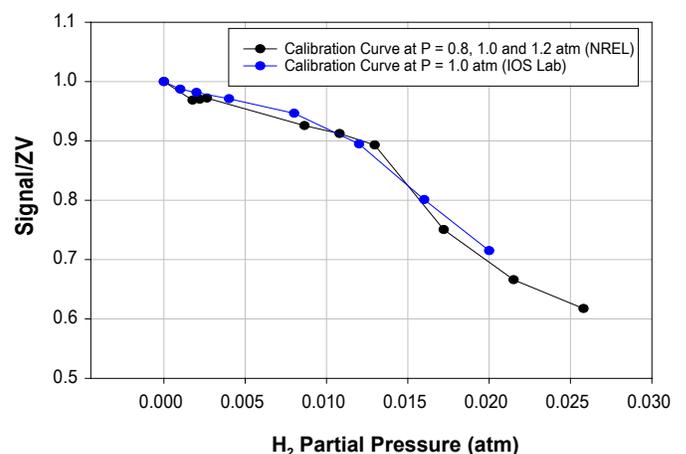

FIGURE 4. Optrode Response Validation Blue – Data taken at NREL; Black – Data taken at IOS.

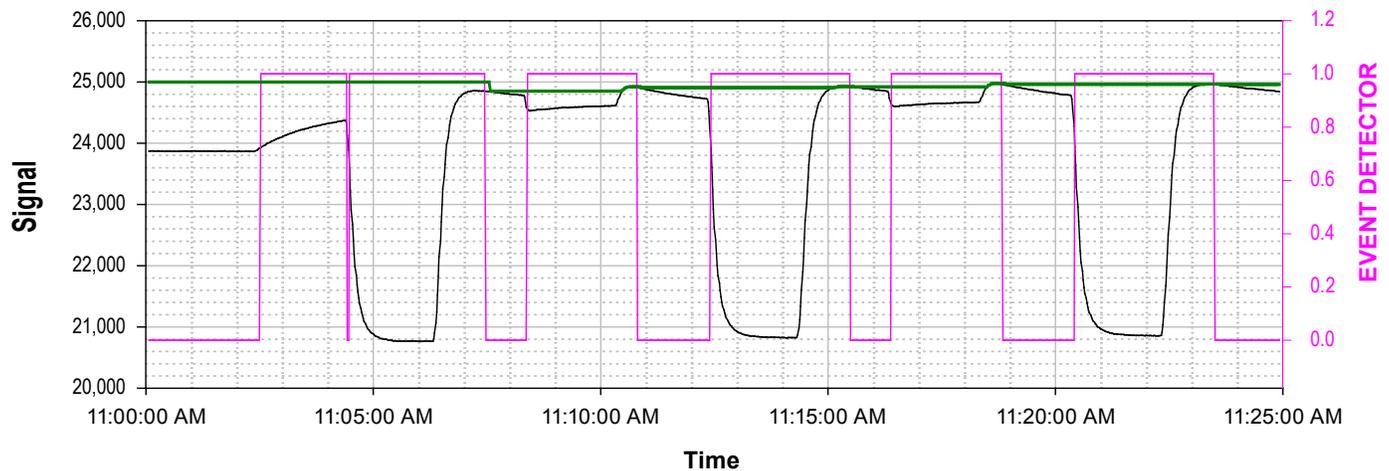

FIGURE 5. Hydrogen Alarm Algorithm Validation Black: optrode response; Red: alarm algorithm signal. Trigger point set at 2% H₂ (50% lower flammability limit, NREL data).

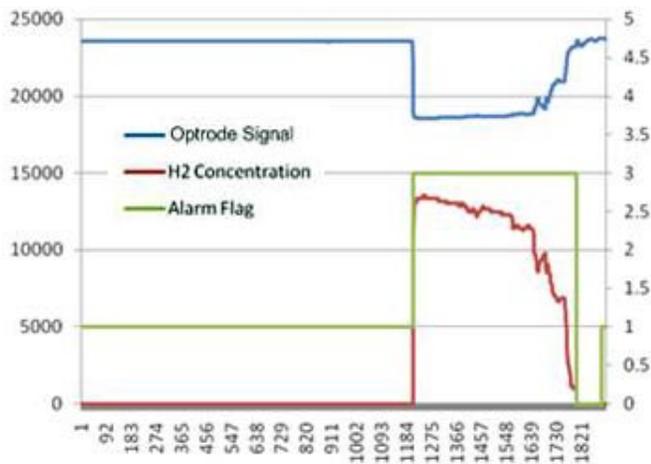

FIGURE 6. Building Release Trial at Sandia National Laboratories

algorithm has confirmed rapid response to all hydrogen concentrations of interest for safety monitoring. Remaining work in the project, which will advance the hydrogen detection leak system to TRL 7 includes:

- Development and installation of upgraded signal processing software.

- Assembly and delivery of 14 prototypes for field testing at DOE-selected sites.
- Extended temperature- and humidity-range testing of detector performance.
- Post-test upgrade of signal processing algorithms and final delivery of prototypes.

Project Start Date: October 12, 2004
Project End Date: October 31, 2010

Fiscal Year (FY) 2011 Objectives

The goal of the Hydrogen Safety Task is to survey and analyze effective risk management techniques, testing methodologies, test data, contribute to development of fundamental knowledge on hydrogen related to hydrogen safety and develop targeted information products that will facilitate the accelerated adoption of hydrogen systems.

The specific objectives of this task are to:

- Survey risk assessment methodologies based on case studies provided by collaborative partners.
- Survey available test data, develop recommendations on modeling and testing methodologies, and share future test plans around which collaborative testing programs can be conducted thus avoiding duplication of work among collaborative partners.
- Collect information on the effects of component or system failures of hydrogen systems.
- Use the results obtained to develop targeted information packages for selected hydrogen energy stakeholder groups.

Technical Barriers

This project addresses the following technical barriers from the Hydrogen Safety section (3.8) of the Fuel Cell

Technologies Program Multi-Year Research, Development and Demonstration Plan:

- (A) Limited Historical Database
- (B) Proprietary Data
- (C) Validity of Historical Data
- (D) Liability Issues
- (E) Variation in Standard Practice of Safety Assessments for Components and Energy Systems
- (F) Safety is not Always Treated as a Continuous Process
- (G) Expense of Data Collection and Maintenance
- (H) Lack of Hydrogen Knowledge by Authorities Having Jurisdiction

Contribution to Achievement of DOE Hydrogen Safety Milestones

This project will contribute to achievement of the following DOE milestones from the Hydrogen Safety section of the Fuel Cell Technologies Program Multi-Year Research, Development and Demonstration Plan:

- **Milestone 2:** Develop sensors meeting technical targets. (4Q, 2012)
- **Milestone 7:** Complete risk mitigation analysis for baseline transportation infrastructure systems. (1Q, 2012)
- **Milestone 8:** Complete investigation of safe refueling protocols for high pressure systems. (1Q, 2012)
- **Milestone 9:** Complete risk mitigation analysis for advances transportation infrastructure system.s (1Q, 2012)
- **Milestone 12:** Complete research needed to fill data gaps on hydrogen properties and behaviors. (2Q, 2010)

FY 2011 Accomplishments

In 2010, the task continued to compare experimental data with risk analysis methods to validate the models and further close the knowledge gaps identified in earlier work. The subtask also completed the development of the Hydrogen Technical Experimental Database (HyTEX). Starting in late 2009, the populating of the data base with data from participating countries was begun. Technical progress on the development of risk informed approval criteria for hydrogen projects to provide a solid basis for risk informed codes and standards was completed.

- Established a list of relevant engineering models that had been used to evaluate the safety of hydrogen systems, categorized them, and performed a comparative analysis with actual testing data.

- Several dispersion models were further developed in 2009 by extending their capabilities to include surface and transient effects (November 2009).
- Developed a more detailed thermal radiation model.
- Completed development of HyTEX.
- Task participants presented many papers at technical conferences on subjects that dealt with the collaborative work.
- The International Energy Agency (IEA) Hydrogen Implementing Agreement co-organized the September 2009 Third International Conference on Hydrogen Safety and Task 19 members presented more than 10 technical papers.

Introduction

Acceptability of new systems is traditionally measured against regulations, industry and company practices and the judgment of design and maintenance engineers, however contemporary practice also incorporates systematic methods to balance risk measurement and risk criteria with costs. Management decisions are increasingly relying on quantitative risk assessment (QRA) for managing the attainment of acceptable levels of safety, reliability and environmental protection in the most effective manner. QRA is being applied more frequently to individual projects and may be requested by regulators to assist in making acceptance and permitting decisions. This task was approved by the executive committee of the IEA Hydrogen Implementing Agreement (HIA) in October 2004. The Task is currently comprised of 11 participating countries.

Approach

This task, aimed at reducing the barriers to widespread adoption of hydrogen energy systems, is being accomplished within three subtasks:

Subtask A. Risk Management - To survey QRA methodologies and compare assessments of hydrogen systems with conventional fuels to develop recommendations for modeling and testing methodologies around which collaborative testing programs can be conducted. Subtask A Risk Management is concentrating on the following four activities:

- Develop uniform risk acceptance criteria and establish link with risk-informed codes and standards.
- Develop a list of appropriate engineering models and modeling tools. Develop simple but realistic physical effects models for all typical accident phenomena (i.e., jet fires, vapor cloud explosions, flash fires, boiling liquid expanding vapor explosions, pool fires, etc.) for education and training, design evaluation and simplified quantitative risk analysis purposes.

- Develop a methodology for consistent site risk assessment based on the HyQRA approach.
- Release updates to all published products: Risk assessment methodology survey, knowledge gaps white paper and Review and comparison of risk assessment studies.

Subtask B. Testing and Experimental Program - To conduct a collaborative testing program to evaluate the effects of equipment or system failures under a range of real life scenarios, environments and mitigation measures. This subtask will summarize and ultimately coordinate and guide the experimental programs being conducted within the 11 countries participating in the task. The approach is to identify such testing programs, the facilities being used, and to coordinate the activities to fill in the data and knowledge gaps for the development of risk informed codes and standards. Subtask B focuses on both testing and experimental data, i.e., testing data as collected by checking the performance of applications and equipment and experimental data as collected by experiments with hydrogen release, ignition, fire, explosions and preventive and protective measures.

Subtask C. Information Dissemination - To disseminate results of the task through targeted information packages for stakeholders. An important aspect of information dissemination is to ensure that the review and vetting of all work products for Task 19 are consistent with the requirements and procedures for producing, approving and distributing various types of IEA reports and other information products. A protocol has been adopted by Task 19 partners and is being applied appropriately for Task 19 work. It is expected that several of these Subtask C products will be updated and enhanced over the course of the period covering Task 19 through October, 2010.

Results

The IEA HIA Task 19 on Hydrogen Safety was approved in FY 2004 and the first task definition meeting was held in Washington, D.C. in June 2004. The Task 19 participants conducted their 11th and 12th meetings in FY 2011. FY 2011 task participation is comprised of experts as noted in Table 1.

The active work on Task 19 ended very early in FY 2010. A draft Final Technical Management Report was submitted to the IEA HIA Secretariat in May 2011. The HIA Secretariat is in the process of changing the format and enhancing the content of these reports and as a result the final report is waiting that information and will revise the report to comply as soon as it is available.

In 2010, the task continued to compare experimental data with risk analysis methods to validate the models and further close the knowledge gaps identified in earlier work. The subtask also completed the development of the HyTEX. Starting in late 2009, the populating of the data base with

data from participating countries was begun. Technical progress on the development of risk informed approval criteria for hydrogen projects to provide a solid basis for risk informed codes and standards was completed.

Risk Management

Prior to 2010, the task had established a list of relevant engineering models that had been used to evaluate the safety of hydrogen systems and categorized them. In past year, they were compared to each other to assess their limitations and validity. Part of this effort was achieved through comparing the engineering models to actual testing data. Several dispersion models were further developed in 2009-2010 by extending their capabilities to include surface and transient effects. A more detailed thermal radiation model was also developed that would account for crosswinds.

A risk assessment methodologies survey was completed for existing risk assessment methodologies to identify their key elements, approaches, methodologies, methods of analysis, key results and recommendations, and post-study developments. Keeping this information in one document was useful to the ongoing evaluation to ascertain their differences and applicability. The survey also identified

interesting findings when each was reviewed and compared. This gave insights to allow the identification of knowledge gaps. It was intended that this document be continually updated and new information was identified. This survey was followed by a comparative analysis of the available risk assessment studies.

A knowledge gaps report which was started at the beginning of the Task 19 was updated and will continue to be updated in the new Task 31. The goal of this activity was to focus research and development resources on critical topics for which there was insufficient information to complete a detailed QRA new commercial systems. Improved safety comes from understanding the outcomes and probabilities of undesirable events that may occur with new technologies, and by mitigating any unacceptable risks posed by these new technologies. In this regard, while a lot is known about hydrogen combustion and its safe handling, it is important to realize that hazards with new hydrogen technologies that are unrecognized or not completely understood are difficult to mitigate. As a result, before appropriate mitigations can be developed, the underlying risks must be identified, quantified, and be well understood. In a white paper, the IEA Task 19 hydrogen experts tried to identify knowledge gaps and barriers for selected applications and to indicate how they can be overcome.

Testing and Experimental Program

An inventory of existing testing and experimental data is in progress and the participants have started sharing information during and beyond the Task 19 into Task 31 which was approved in October 2010. Ongoing work and future activities will start with a search by the partners for available data existing in their respective countries and around the world. In order to secure a continuing refinement of the survey, the data and/or references will be stored in HyTEx. The Subtask B databases HyTEx, Hydrogen Projects and Hydrogen Testing and Experimental Facilities will be used as a source of information for any missing data in relation to the knowledge gaps as defined by and resulting from the Subtask A activities. If data is not available this could give rise to recommendations on new testing and experimental programs. Several technical knowledge gaps were identified in Subtask A and described in the white paper 'Knowledge Gaps in Hydrogen Safety'. Currently identified knowledge gaps are: spontaneous ignition, protective barriers and consequence modeling.

Development of Targeted Information Packages for Stakeholder Groups

The targeting of information packages for selected hydrogen energy stakeholder groups is central to the work and objectives of Task 19, currently focused on risk assessment methodologies and studies, testing and experimental programs, safety training and knowledge resources and hydrogen facility siting. Information packages

can take a variety of forms: IEA publications, publicly available web-based tools, databases and documents for use by Task 19 partners.

Conclusions and Future Directions

The current task ended in October 2010 and a new task on hydrogen safety was approved to continue to build on the very effective collaboration of this six-year effort. A kick-off meeting for the new task was held in Karlsruhe, Germany in April 2011. It is anticipated that one of the major outcomes of this ongoing work will be a technical and credible basis for the development of risk informed codes and standards that will not be unnecessarily restrictive. This will eliminate a

major barrier to the widespread commercial adoption of hydrogen energy systems. Future work will support this goal by improving hydrogen risk assessment methodologies and quantitative risk analysis and closing knowledge gaps with regard to consequences of hydrogen related accidents and incidents, the effects of mitigation methods, and failure probabilities of system components.

Start Date: August 2007

Projected End Date: Project continuation and
direction determined annually by DOE

- Response Time: less than one second
- Accuracy: 5% of full scale
- Gas Environment: ambient air, 10%-98% relative humidity range
- Lifetime: 10 years
- Resistant to Interferents (e.g., hydrocarbons)

Accomplishments

(The project did not receive funding in FY 2011.)

- Winner of a 2011 R&D 100 Award, for “Hydrogen Safety Sensor Based on Nanostructured Palladium.” Our hydrogen sensor was recognized by R&D Magazine as one of the top 100 technologically significant products that was introduced into the marketplace over the past year. Our entry was one of three inventions recognized in the Safety and Security technology category.

Fiscal Year (FY) 2011 Objectives

- Develop sensing technology that achieves DOE research and development (R&D) targets for hydrogen safety sensors.
- Characterization of response time, recovery time, sensitivity and accuracy within the operating temperature range.
- Demonstrate sensor performance and compliance with safety goals.
- Establish partnership to develop pre-commercial sensor prototype.

Technical Barriers

The project addresses the following technical barriers from the Hydrogen Safety section (§3.8.4) of the Fuel Cell Technologies Program Multi-Year Research, Development and Demonstration Plan (October 2007):

- (D) Liability Issues
- (E) Variation in Standard Practice of Safety Assessments for Components and Energy Systems

Technical Targets

The long-term project objective is to achieve commercialization and regulatory acceptance of fiber-reinforced polymer pipeline technology for hydrogen transmission and distribution. Accordingly, the project tasks address the challenges associated with meeting the DOE hydrogen delivery performance and cost targets for 2017:

- Measurement Range: 0.1%-10%
- Operating Temperature: -30 to 80°C

Introduction

Utilization of hydrogen as a transportation fuel requires comprehensive safety management during its storage, handling and use. Although safety-by-design and passive mitigation systems are the preferred methods for safety management, it is vitally important to develop technologies that can detect hydrogen releases and alert to system failures. The DOE Fuel Cell Technologies Program’s Hydrogen Safety sub-program recognizes the need to develop and commercialize hydrogen sensors that provide the appropriate response time and the sensitivity and accuracy necessary for use in safety applications, thereby reducing risk and helping to establish public confidence in the hydrogen infrastructure.

This project addresses the above needs by developing, proving and commercializing a hydrogen detection device based on nanostructured thin film palladium microcantilever arrays. This hydrogen sensor has been shown to provide major performance improvements over existing and other recently developed sensors. The overall objective is to develop sensor technology that achieves DOE R&D targets for hydrogen safety sensors at lower cost and with the potential for wide-area hydrogen gas detection.

Approach

Microcantilever-based chemical sensors were first seriously explored as a trace gas sensing technology in 1990s with the first reported use of Pd-coated microcantilevers for sensing H₂ occurring in 2000. Adsorption of a gas onto a thin film surface can cause large changes in stress

and consequent bending of a thin cantilever structure. This bending response can be sensitively detected using piezoresistive, capacitive and optical techniques such that sub part-per-billion sensitivities are achievable. Microcantilever-based chemical sensors have been shown to have high sensitivity, wide dynamic range and fast response times. Optically read microcantilever sensors are particularly advantageous in the presence of combustible or explosive gases and vapors (e.g. H₂) due the possibility of vapor ignition when using heated or electrically operated sensors. Other advantages of this sensing technique include very low power consumption, and their potential use in distributed wide area sensor networks allowing multiple low cost chemical sensors to be located at storage or processing facilities (e.g. in the H₂ fuel economy) or on H₂-powered or transportation vehicles.

One of the most challenging aspects of detecting and quantifying the amount of a low concentration gas or vapor in the environment is the effect of potential interferents on the gas sensor response. Interferents can lead to false positive responses or suppressed responses to the gas being detected. One approach to overcoming this problem is the use of a multiplexed sensor array, with each sensor having a distinct sensitivity response to the gas or vapor of interest and any potential interferents. A much simpler approach is to use a single sensor, or small array of sensors, to sense a single gas species, as the computational processing of the array responses is much less intensive than for the multiplexed sensor array. The single sensor mode of operation is feasible if a coating can be found that responds primarily to the gas species of interest with minimal response to any potential interferents. Palladium has previously been used as a sensing medium in a number of sensor technologies due to its strong and reasonably unique response to H₂. The possibility of using Pd-coated microcantilever sensors to detect H₂ leaks has been examined in several previous studies. The issue with most previous thin-film Pd studies, and all of the previous microcantilever-based work, is that the sensor response and recovery times are far longer than acceptable for most applications; response times for these microcantilever-based H₂ sensor studies varied from a few minutes to as long as 1 hour. The long response and recovery times are attributed to the long diffusion time for elemental hydrogen to diffuse into and out of the palladium film to form palladium hydride.

Our approach is to use a new nanostructured Pd/Ag alloy that we developed specifically for the hydrogen sensing application. Microcantilever sensors coated with this alloy have fast, near ideal response characteristics when monitoring low concentration H₂ gas. In particular, the response and recovery times measured with these sensors are far shorter (<10 s) than those reported in all previous microcantilever-based H₂ sensor studies. The development work performed to optimize the performance of our sensor consisted of efforts to increase the sensitivity and dynamic range, to minimize the response and recovery times, to improve its resistance to interferents, and to increase its

accuracy, repeatability and lifetime. We are presently working on the development of a prototype that can be performance-evaluated by third parties and adapting the sensor system for use in wide-area sensing.

Results

We conducted sensitivity and performance measurements of the Pd-Ag functionalized, optically read microcantilever using a benchtop setup consisting of the microcantilever in a gas flow cell, an optical readout system, a flow control valve and sample loop, and a LabVIEW®-based data acquisition system. The threshold and dynamic range test results revealed a lower-limit-detection of 0.01% (100 ppm) H₂ in argon, with three orders of magnitude dynamic range. Response and recovery times for 4% H₂ in argon were <3 s and <10 s, respectively. Over an eight-month period the sensor accuracy and repeatability remained constant within ±2%, indicating that the projected operational lifetime of this early version of the sensor could be as long as several years. Measurements of sensor specificity to common impurities and carrier gases (CO₂, CH₄, H₂O, N₂, He, CO) showed that in all cases, the responses from the interferents were an order of magnitude or more smaller than that observed for H₂ at similar concentrations. This degree of discrimination against interfering species will be adequate in all but the most demanding applications.

As illustrated in Table 1, in laboratory tests completed to date, we demonstrated that our microcantilever-based H₂ sensors meet all but the most stringent requirements for automotive sensing applications.

Conclusions and Future Directions

We have demonstrated that Pd-Ag functionalized, optically read microcantilever H₂ sensors have nearly ideal attributes required for distributed low-cost sensing of hydrogen leaks in many applications. These include high sensitivity, wide dynamic range, adequate response and recovery times and repeatable response. These sensors have been operating in a laboratory environment for more than a year without noticeable changes in sensitivity, specificity and response and recovery times. Work is also progressing on the development of low-cost portable detector prototypes that can be used to validate the expected performance of this potentially lower cost, better performing sensing technique. To this end, we have developed and done preliminary performance studies on two generations of portable instrumentation with encouraging results. We plan to report on these studies at a later date.

In the next project year we plan to:

- Fabricate a field portable instrument that can be evaluated at the National Renewable Energy Laboratory (NREL) Safety Sensor Testing Laboratory:

TABLE 1. ORNL microcantilever-based H₂ sensor meets all requirements for stationary and automotive applications and possibly exceeds performance of other recent sensors.

	Performance Requirement*	ORNL Measured Performance	Competitor #1 (IOS)	Competitor #2 (LANL)
Sensitivity Range	< 0.1% to > 4%	0.01 – 10%	0.2 – 10%	0.1% - 2%
Survivability Limit	100%	Linear response to 100% H ₂	unknown	unknown
Response Time	Automotive: < 3 sec Stationary: < 30 sec	1-3 sec	> 5 sec	3 – 8 sec; figures show much longer response times
Recovery Time	Automotive: < 3 sec Stationary: < 30 sec	3-10 sec	> 5 sec	3 – 8 sec; figures show much longer recovery times
Temperature Range	Automotive: -40°C to +125°C Stationary: -20°C to +50°C	Yes	Yes	Yes
Pressure Range	Automotive: 62-107 kPa Stationary: 80-110 kPa	Yes	Yes	Yes
Ambient Relative Humidity Range	Automotive: 0 – 95% Stationary: 20 – 80%	0-100% - little response to changes in humidity	significant response to changes in humidity	unknown
Interferent Resistance	No false positive responses	Excellent	poor – H ₂ S, CO, CH ₄	unknown
Power Consumption	< 1 Watt	0.2-0.5 Watt	0.5 watt	5-10 watt
Operating Temperature	Room temperature	room temperature	room temperature	535°C
Lifetime	Automotive: 6,000 hr Stationary: > 5 years	Demonstrated > 12 months	unknown	2000 hours; Response times much longer at longer times
Accuracy and Repeatability	Automotive: 5-10% Stationary: 10%	> +/- 5%	> +/- 5%	+/- 10%

*See L. Boon-Brett et al., "Identifying performance gaps in hydrogen safety sensor technology for automotive and stationary applications," *Int. J. Hydrogen Energy*, **35**, 373-384 (2010).

- The goal of the testing is to demonstrate that the sensor can meet all safety goals, including a projected longevity of 10 years. The suite of tests at NREL involves evaluation of the following parameters: short-term repeatability, linearity/dynamic range, sensitivity to H₂ mixtures in air, atmospheric pressure sensitivity, sensitivity to temperature and relative humidity, long-term stability, response and recovery kinetics, and sensitivity to interferents.
- We expect that the testing at NREL will be done with the technical and financial assistance of a commercialization partner.
- Complete technology transfer activities with an industrial partner:
 - Our commercialization plan will begin with an exploration of the market potential of our sensor technology, assessing factors such as the size of the potential market for our hydrogen sensor, the life-cycle cost target, the necessary performance characteristics, and future sales trends for hydrogen sensors.
 - Following the market assessment we will perform a technology readiness level assessment to determine the amount of effort that will be required to get the

technology to the desired end product. A primary role of the industrial partner will be to evaluate the various risks involved in getting the sensor to market such as business model performance, marketing cost analysis, and execution risks.

IX. EDUCATION

IX.0 Education Sub-Program Overview

The Education sub-program supports and facilitates hydrogen and fuel cell demonstration, deployment, and early market introduction by providing technically accurate and objective information to key target audiences that can help transform the market (see Table 1).

TABLE 1. Key Target Audiences for the Education Sub-Program

Target Audience	Rationale
Code Officials	Code officials must be familiar with hydrogen to facilitate the permitting process and local project approval.
First Responders	Firefighters, as well as law enforcement and emergency medical personnel, must know how to handle potential incidents; their understanding can also facilitate local project approval.
Local Communities/ General Public	Local communities will be more likely to welcome hydrogen and fuel cell projects if they are familiar with hydrogen.
Potential End-Users	Potential early adopters need information about commercially available hydrogen and fuel cell products and the opportunities for incorporating the technologies into their operations.
State and Local Government Representatives	A broad understanding of hydrogen encourages favorable decision-making regarding opportunities for near-term deployment and lays the foundation for long-term change.
Middle School and High School Teachers and Students	Teachers need technically accurate information and usable classroom activities to educate the next generation of potential researchers, engineers, policy-makers, and end-users about the technologies.
University Faculty and Students	Graduates are needed for research and development in government, industry, and academia.

The Education sub-program develops and disseminates information resources and conducts training. It strives to communicate a balanced message to help target audiences become familiar with hydrogen and fuel cell technologies and how they fit in the portfolio of renewable energy and energy-efficiency options. To aid with market introduction, the sub-program helps target audiences develop an accurate understanding of hydrogen safety, recognize opportunities for deployment in near-term markets, and understand the role of early markets in facilitating the use of hydrogen and fuel cells.

Goals

Educate key audiences about hydrogen and fuel cell technologies to facilitate near-term demonstrations and commercialization in early markets and longer-term widespread commercialization and market acceptance.

Objectives

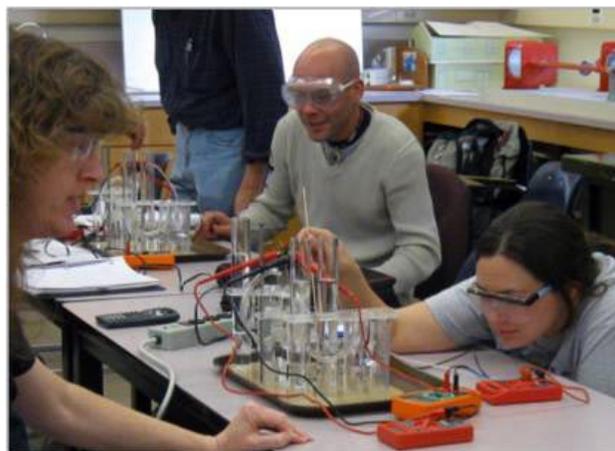

The Education sub-program is closely coordinated with the Program's activities in technology demonstration and validation; safety, codes and standards; and early market deployment and associated market transformation activities. It is also coordinated with state- and regional-based hydrogen and fuel cell outreach programs. These integrated efforts form a comprehensive strategy to transform success in demonstrating and deploying technologies into success in the broader marketplace. Specific objectives for the Education sub-program include the following:

- Increase the acceptance and inclusion of hydrogen and fuel cell technologies as a part of a clean energy portfolio in federal, state, and local government investments, as well as private sector investments.

- Reduce the “soft costs” associated with the deployment and early adoption of hydrogen and fuel cell technologies in multiple applications (e.g., insurance, permitting, uniform codes and standards) through education, outreach, and training of “second generation” clean energy professionals.
- Increase general knowledge and awareness of the benefits of the use of hydrogen and fuel cell technologies in multiple applications among key target audiences.
- Increase awareness of the broad range of applications for fuel cells and hydrogen—beyond light-duty vehicles and buses.

Fiscal Year (FY) 2011 Status

The Education sub-program continued to support state and regional outreach efforts by providing consistent messages, readily available information resources, and other activities, as appropriate. The sub-program’s seven outreach projects are focused on states with an active hydrogen and fuel cell presence, and they are working to develop case studies, best practices, and technical assistance resources to help decision-makers identify and assess opportunities for future deployment. In the area of academics, the sub-program also continued to support university, high-school, and middle-school education, including dissemination of lesson plans, curricula, and laboratory materials. Continuing its work with first responders, the sub-program conducted several sessions of a hands-on “prop course” for firefighters and continues to maintain the Web-based “Introduction to Hydrogen Safety for

First Responders,” which is registered on the Training-finder Real-time Affiliate Network website, a central repository for health training courses, with 30,000 members. The sub-program also continued to work closely with the Safety, Codes and Standards sub-program, expanding the code and permitting official e-learning package with indoor fueling information and developed permitting case studies, in support of increasing early market deployments.

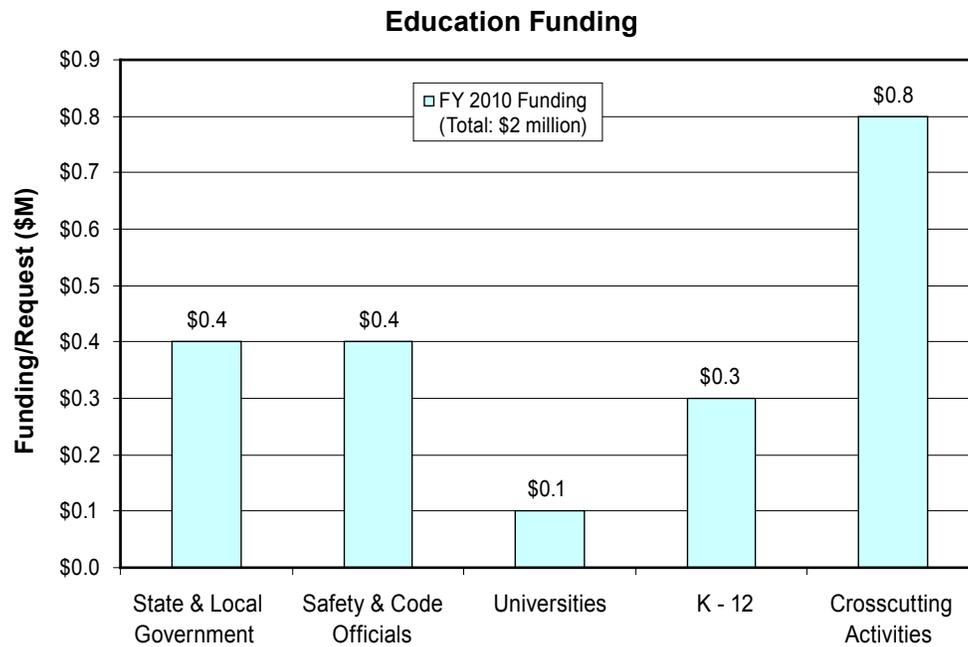

FY 2011 Accomplishments

- In coordination with the Systems Analysis sub-program, developed a model to analyze the economic impacts of early market deployment of fuel cells in primary power, backup-power, and material-handling applications. The user-friendly spreadsheet tool is used to calculate the impacts of the production, installation, and utilization of hydrogen and fuel cells on a regional or national level. Early versions of the model were demonstrated to stakeholders and industry representatives to obtain feedback on desired functionality, granularity, and outputs.
- Completed deployment and outreach activities with two Caterpillar electric trucks, each powered by a Hydrogenics Fuel Cell Power Pack. Continued to educate stakeholders on the benefits of fuel cell and hydrogen technologies in material handling applications including facility management, operators, maintenance personnel, safety groups, first responders, authorities having jurisdiction, and technical/community colleges. Continued demonstration of fuel cell and hydrogen technology for lift trucks in real-world applications at large prominent companies.
- Continued to promote and deploy the “H2 Educate” middle-school learning module—reaching a total of more than 8,800 teachers in 35 states since the project was launched. Preliminary survey results indicate that over 90 percent of survey participants felt that the resources have made it possible to teach hydrogen more often and in more detail and that the materials increased student knowledge and understanding of hydrogen.

- Developed network of key stakeholders in the Northeast region—in order to leverage regional efforts through increased collaboration—including Northeast Energy & Commerce Association, Clean Energy States Alliance, Massachusetts Hydrogen Coalition, Hydrogen Energy Center, and New Energy New York.
- Identified target locations for fuel cell deployment in the Northeast service area based on deployment criteria including energy intensive commercial building types identified by the Environmental Protection Agency’s Commercial Building Energy Consumption Survey and mapped out locations using ArcGIS software.
- Developed a Web-based virtual Regional Resource Center that provides online information, models, and other tools to assist local, state, and regional planners in the Northeast to quantify the costs and benefits of hydrogen and fuel cell technology at potential sites. Models address environmental value, energy management, renewable hydrogen generation, distributed technology comparisons, and cost/economics of stationary fuel cells.
- Continued to facilitate the Hydrogen Student Design Contest. In 2011, the contest challenged teams to plan and design a residential hydrogen fueling system. Fifty-four university teams registered from 19 countries, including seven of the top 20 engineering schools in the world.
- Developed videos to be aired on TV and posted online to YouTube and other sites, including the development of two segments for Motorweek entitled “Hydrogen and Fuel Cells Emerging Markets” and “Vehicles and Infrastructure Update.”
- Produced report and briefing paper on hydrogen production and storage for distribution to state policymakers and others. Developed case studies on early markets for hydrogen and fuel cell technologies including: fuel cell lift trucks, combined heat and power, and telecommunications backup power.
- Organized, publicized, hosted, and facilitated five webinars on hydrogen and fuel cell topics of interest to state policymakers, local leaders, and end users. For the last two webinars, more than 300 people registered, including many state policymakers. The sub-program also held three webinars to provide information to stakeholders throughout South Carolina and developed a first-responders webinar workshop.
- Continued to reach influential audiences including state policymakers, financial institutions, business leaders, end users, and others by giving presentations and distributing fuel cell literature and briefing papers at multiple conferences and meetings. Conferences attended in FY 2011 included the Clean Energy States Alliance Fall 2010 Members Meeting, the National Conference of State Legislatures Fall Forum, the Building Energy Conference, the Fuel Cells Finance and Investment Summit, the Ohio Fuel Cell Symposium, and the Northeast Commerce and Energy Association.
- Increased offering of university certificates and minors at universities including a “Graduate Certificate in Hybrid and Electric Vehicles” from Michigan Tech and a hydrogen and fuel cell technology concentration as an option in the engineering program at the University of North Carolina at Charlotte.
- Developed modules to introduce hydrogen and fuel cell technologies to students taking core chemical, mechanical, and electrical engineering courses.
- Facilitated creation of two fuel cell development intern positions at Protonex Technology Corporation for summer 2011; filled these positions with two Humboldt State University engineering students who had previously participated in H2E3 curriculum. Placed summer interns at the National Renewable Energy Laboratory, Oak Ridge National Laboratory, and the National Center for Hydrogen Technology.
- Published the two-week high school curriculum titled “Investigating Alternative Energy: Hydrogen & Fuel Cells.” Held a two-day workshop for teacher professional development in February 2011. Materials were disseminated via 13 presentations to secondary science educators and hydrogen and fuel cell professionals.

Budget

The Education sub-program’s FY 2011 budget and FY 2012 request are zero. New projects that were competitively awarded in FY 2004 and FY 2008 were fully funded in FY 2010. Most projects are scheduled to be completed in FY 2011. Given budget constraints and the need for including hydrogen and fuel cells within the broader Energy Efficiency and Renewable Energy portfolio, education and outreach activities will be coordinated with other DOE-wide efforts. Target audiences have been prioritized according to their near-term relevance and the effect on the use of hydrogen and fuel cell technologies today.

FY 2012 Plans

In FY 2012, the Education sub-program will complete expenditures of prior-year appropriations in relevant areas and focus on facilitating the introduction of hydrogen and fuel cell technologies into early markets. Future efforts will coordinate with other DOE-wide efforts to leverage recent project successes through the development of educational materials and webinars to highlight the benefits of hydrogen and fuel cell technologies.

Project Start Date: October 2010
Project End Date: September 2012

Partner:
RCF Economic and Financial Consulting, Inc., Chicago, IL

Fiscal Year (FY) 2011 Objectives

- Facilitate early market deployment of fuel cells in prime power, backup power and material handling applications by developing a user-friendly tool to calculate economic impacts.
- Calculate gross direct and indirect economic impacts of fuel cell expenditures by state, geographic region, and the nation as a whole.
- Calculate net national changes in jobs and economic output.
- Meet stakeholder needs for identifying industry sectors benefiting most from fuel cell production and deployment.
- Explore impact of different fuel cell production and deployment options on state, regional and national employment, earnings and economic output.

Technical Barriers

This project directly addresses the following technical barriers from the Education section of the Fuel Cell Technologies (FCT) Program Multi-Year Research, Development and Demonstration Plan:

- (A) Lack of Readily Available, Objective, and Technically Accurate Information
- (E) Regional Differences
- (F) Difficulty of Measuring Success

Technical Targets

The project is developing and using a computer model to estimate the impact of deploying stationary fuel cells in early markets. Insights from the model will assist FCT and its stakeholders in estimating employment and other economic impacts from DOE technology development and in identifying fuel cell markets and industrial sectors that are most likely to generate jobs and economic activity.

FY 2011 Accomplishments

- Reviewed existing fuel cell market studies, impact assessment tools and assumptions in the 2008 Report to Congress.
- Identified viable near-term markets and technologies in the stationary power and specialty vehicle sectors.
- Characterized the supply chain (in terms of the dollar purchases from individual industrial sectors per fuel cell kW) for low temperature polymer electrolyte membrane (PEM) fuel cells; developed initial supply chain characterizations for phosphoric acid fuel cell (PAFC) and molten carbonate fuel cell (MCFC) technologies.
- Completed major portions of a spreadsheet model capable of projecting regional or national employment benefits of fuel cell deployment, including:
 - Design and implementation of input and output screens and user interface.
 - Design and implementation of state and regional interfaces.
 - Development of manufacturing cost algorithms incorporating economies of scale, learning-by-doing and technology advancement functions.
- Conducted a series of meetings/webinars with stakeholders including:
 - Connecticut Center for Advanced Technology
 - South Carolina Hydrogen and Fuel Cell Alliance
 - California Fuel Cell Partnership
 - California Stationary Fuel Cell Collaborative
 - Virginia Clean Cities
 - Clean Energy States Alliance
- Demonstrated early versions of the model to stakeholders and industry representatives to obtain feedback on desired functionality, granularity, and outputs.

Introduction

Section 1820 of the Energy Policy Act of 2005 (Public Law 109-58) directed DOE to assess the impact of a large-scale transition to hydrogen on U.S. employment. In response to that directive, RCF Economic and Financial Consulting, Inc., Argonne National Laboratory, and other partners undertook an in-depth analysis of the economic impacts of hydrogen deployment in the transportation sector. That study relied on input-output analysis to estimate net employment changes at the national level and produced a final report which was submitted to Congress in July 2008. But the study did not address the possibility that stationary fuel cells might be the initial wide-scale fuel cell application, with vehicle applications occurring later. Neither did it develop a model to permit the examination of alternative fuel cell deployment scenarios and their employment impacts. Now, however, it is increasingly important to estimate net and gross employment impacts associated with various scenarios of fuel cell early market development. Developing that modeling capability is the focus of this study.

Results

In FY 2011, Argonne National Laboratory and RCF Economic and Financial Consulting began work on the design and implementation of a spreadsheet tool to calculate the economic impact of fuel cell production, installation, and utilization in early markets (i.e., 2015–2020) at the state, regional and national level. Known as the Job and Output Benefits of Stationary Fuel Cells the tool is designed as a user-friendly, spreadsheet-based application. Figure 1 shows the various geographies incorporated into it. Note that the regions are groups of states that correspond to the nine U.S. census regions.

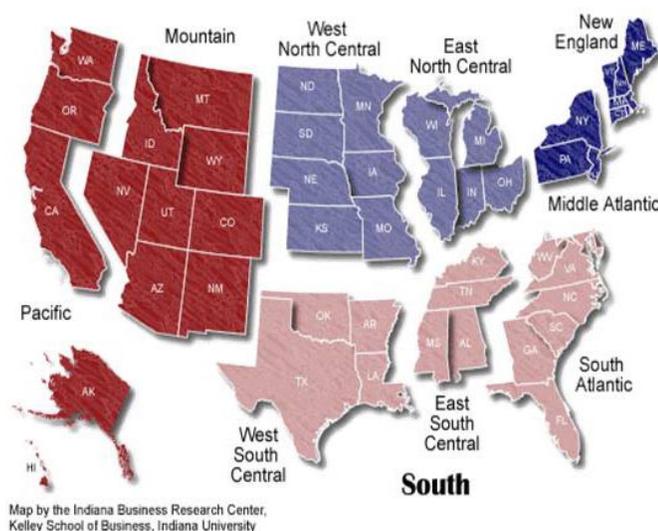

FIGURE 1. U.S. Census Regions

For each of these 60 geographies – 50 states, nine census regions and the nation as a whole – Job and Output Benefits of Stationary Fuel Cells estimates the effect of fuel cell deployment. It does so by adjusting the dollar flows among 440 existing economic sectors. Supply chains for PEM fuel cell, PAFC and MCFC technologies are used to modify those flows to represent purchases by and sales from a nascent fuel cell industrial sector. Figures 2 and 3 illustrate supply chains for the manufacture of PEM fuel cell stacks and balance of plant (BOP). Similar supply chains were developed for MCFC and PAFC stacks and BOP. Note that the underlying dollar flow among existing sectors are based on the Regional Input-Output Modeling System (RIMS) input-output model.

In addition to selecting a geographic area or region of interest and a fuel cell type, users must also select an application (material handling, backup power or prime power) and a market (e.g., Class 1-2 or Class 3 forklifts, cell phone towers or emergency responders) as well as such other variables as fuel cell size, current and future in-region production volumes, imports and exports, and analysis time. These variables define both the overall scenario and anticipated changes in fuel cell manufacturing cost. The manufacturing cost module incorporates the combined effects of manufacturing scale, learning and technology development, based on recent work by Greene et al. (Status and Outlook for the U.S. Non-Automotive Fuel Cell Industry: Impacts of Government Policies and Assessment of Future Opportunities, ORNL/TM-2011/101, May 2011.)

Figure 3 illustrates a representative scenario for deploying roughly 2,000 domestically produced forklifts per year plus a much smaller number of imported units in the out years. Note that indirect employment associated with fuel cell manufacturing, installation and fueling/operation and maintenance (O&M) exceeds direct employment for those categories in all years. Also, since employment in fuel cell installation and fueling/O&M depends on the stock of fuel cells in operation, it grows faster than employment in fuel cell manufacturing which tracks new sales.

Conclusions and Future Directions

FY 2011 work focused on developing a prototype spreadsheet model to estimate gross state, regional and national economic and employment impacts from the manufacture, installation fueling and operation of fuel cells in distributed prime power, backup power and material handling (e.g. forklift) applications. That work included a review of technology and manufacturing progress; model design and development; discussions with industry and subject matter experts to characterize fuel cell costs and supply chains; the formation of a stakeholder panel to provide input on model design, functionality, data sources and validation; and meetings/presentations to stakeholder groups. FY 2012 work will build on that

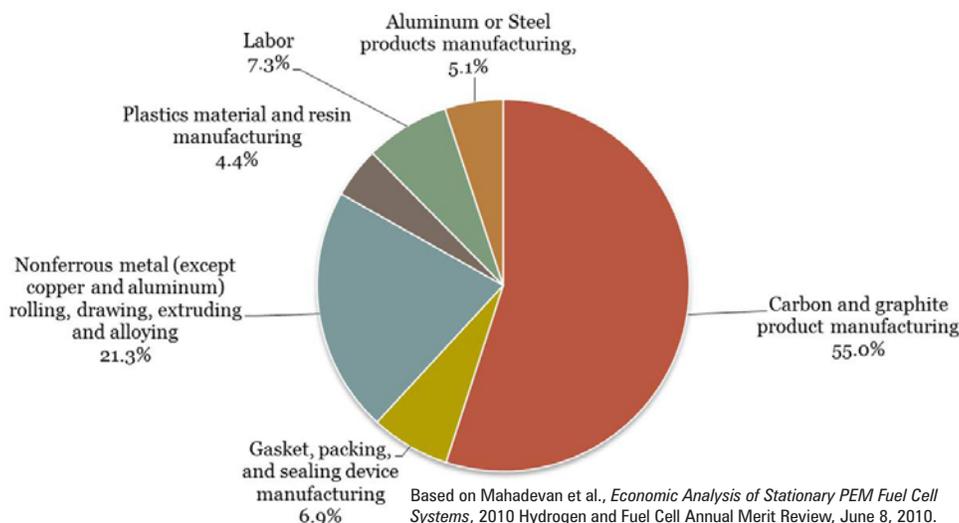

FIGURE 2. Supply Chain for PEM Fuel Cell Stack

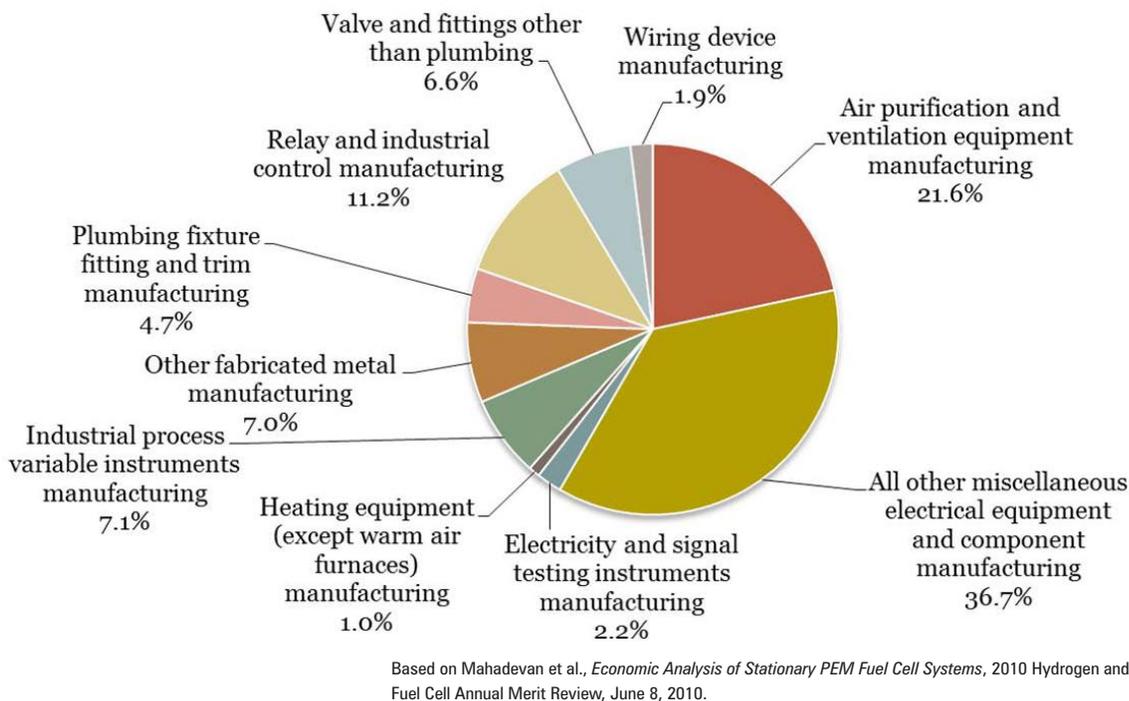

FIGURE 3. Supply Chain for PEM Fuel Cell Balance of Plant

effort, incorporating stakeholder recommendations for enhancements to the functionality and scope of the model, as well as review and beta testing of the tool, and application of it to estimate the employment impacts of projects funded under the American Recovery and Reinvestment Act.

Model enhancements include adding solid oxide fuel cell and high temperature PEM options for prime power, distributed hydrogen production as an option for forklift fueling, the capability of modeling site-specific installations, and the ability to estimate employment impacts of DOE’s hydrogen and fuel cell research and development funding.

Contract Number: DE-FC36-08GO18116 / 003

Project Start Date: September 1, 2008

Project End Date: August 30, 2011

Fiscal Year (FY) 2011 Objectives

- Foster strong relationships among federal, state, and local government officials, industry, and appropriate stakeholders.
- Serve as a conduit between the DOE and state and local government decision makers.
- Provide technically accurate and objective information to government decision-makers and identified stakeholders to improve/enhance decision making.
- Increase the knowledge base and improve awareness regarding hydrogen and fuel cells.
- Provide support for hydrogen and fuel cells in early market applications, consistent with DOE's market transformation efforts.

Technical Barriers

This project addresses the following technical barriers from the Education section of the 2009 Fuel Cell Technologies Program Multi-Year Research, Development and Demonstration Plan:

- (A) Lack of Readily Available, Objective, and Technically Accurate Information
- (C) Disconnect Between Hydrogen Information and Dissemination Networks

Contributed to Achievement of Education Milestones

This project will contribute to the achievement of the following DOE milestones from the Hydrogen Education section of the 2009 Fuel Cell Technologies Program Multi-Year Research, Development and Demonstration Plan:

- **Milestone 17:** Hold "Hydrogen 101" seminars (4Q, 2008 through 4Q, 2012).
- **Milestone 30:** Evaluate knowledge and opinion of hydrogen technology of key target audit audiences and progress toward meeting objectives. (4Q, 2012).

Related milestones in Task 3 (Educate State and Local Government Representatives) and Task 7 (Assess Knowledge and Opinions of Hydrogen Technologies) of the above reference have both been achieved with support from the State and Local Government Partnership.

FY 2011 Accomplishments

- Identified key stakeholders in Connecticut such as legislators, state agencies (utility, environment, energy, transportation, etc.), mayors, first selectmen, public works officials, council of governments and completed a pre and post-project survey to assess knowledge.
- Expanded database to include key stakeholders in the "Northeast Region" while strengthening existing relationships with state stakeholders, and regional partners, including Northeast Energy & Commerce Association, Clean Energy States Alliance, Massachusetts Hydrogen Coalition, Hydrogen Energy Center, and New Energy New York.
- Undertook economic modeling through the use of an IMPLAN economic model to assess the economic impact of the hydrogen and fuel cell industry in terms of its direct, indirect, and induced economic effects, in all eight states.
- Identified target locations for fuel cell deployment in the service area based on deployment criteria including energy intensive commercial building types identified by Environmental Protection Agency's (EPA's) Commercial Building Energy Consumption Survey (CBECS) and mapped out locations using ArcGIS software.
- Developed a web-based virtual Regional Resource Center (RRC) that provides online information, models and other tools to assist local, state and regional planners quantify the costs and benefits of hydrogen and fuel cell technology at potential sites. Models address environmental value, energy management, renewable hydrogen generation, distributed technology comparisons, and cost/economics of stationary fuel cells.
- Developed a comprehensible plan with the Connecticut Department of Transportation for hydrogen fueling infrastructure and vehicles for Connecticut.
- Organized a regional briefing for Northeast stakeholders held on July 22, 2010 in Westborough, Massachusetts.
- Presented at regional planning agencies/regional councils of government; the Green Energy & Building Expo and Connecticut Power and Energy Society

Meeting; exhibited at the Connecticut Conference of Municipalities Conference; and participated on bi-monthly State and Regional Initiative calls.

- Presented at events such as the Fuel Cell and Hydrogen Energy Association Annual Conference, the Northeast Sustainable Energy Association Annual Conference “Building Energy 11”, and the 2010 Fuel Cell Seminar and Exposition.
- Developed and held the Fuel Cells for Municipalities Workshop on September 22, 2009 in Glastonbury, Connecticut and a legislative briefing/forum for state policy makers on January 22, 2010 in East Hartford, Connecticut.
- Provided technical and economic information to municipal decision makers including hydrogen and fuel cell benefits and project analysis.
- Participated on the NEPOOL ISO Planning Advisory Committee to identify regional energy issues, problems and solutions; and in a webinar organized by the Clean Energy States Alliance that addressed hydrogen and fuel cell technology and the development of guidance document “Roadmaps” to enhance support for the industry and facilitate deployment.
- Developed two hydrogen and fuel cell educational videos titled “Hydrogen and Fuel Cell Technology, Connecticut Hydrogen Fuel Cell Coalition” and “Hydrogen and Fuel Cell Technology, a World of Opportunity.”

Introduction

This project assists with the building of partnerships between the DOE, states and municipalities. CCAT has developed a structure with an approach that provides an opportunity for federal, regional, state, and local involvement to encourage and promote the use of hydrogen and fuel cell technology. The structure includes leadership by the DOE; the establishment of collaborative meetings, workshops, and briefings to provide information to municipal and state decision makers; the provision of resources for potential developers to assess opportunity for deployment; support for state stakeholder groups to implement initiatives in support of state and federal policies; identification and assessment of economic benefits of the hydrogen and fuel cell industry and implementation of strategies to facilitate the deployment of hydrogen and fuel cell systems in the state.

The structure also includes a virtual RRC developed by CCAT that provides online information, models, and other tools to assist decision makers and end users to quantify the costs and benefits of hydrogen and fuel cell technology at potential sites. The RRC provides tools for implementation to assist local and state planners and decision-makers in identifying potential opportunities for the deployment of hydrogen and fuel cell technologies. The models available

through the RRC are used to assess environmental value, energy management, renewable energy, cost and economics, and comparisons of competing technologies. CCAT is also developing guidance documents or Hydrogen/Fuel Cell “Roadmaps” for the New England States, New York, and New Jersey.

Approach

CCAT’s approach has been to develop resources for hydrogen and fuel cell deployment to aid in the education of state and local decision makers. These resources include online information, models, and tools for potential users to analyze the costs and benefits of hydrogen and fuel cell technology. Coordination and cooperation is sought by both local and state decision-makers in order to introduce hydrogen and fuel cell technology in early market applications. The project uses local “bottom-up” decisions guided by state/regional “top-down” assistance to help reduce conflict, improve state/regional and municipal relations, and provide better solutions to community-based energy problems. Because of the high risk and high capital cost of implementing new technologies, CCAT also coordinates with local, state, and regional decision makers to identify innovative funding and procurement mechanisms, such as group purchases and corporate tax credits, to encourage market growth, reduce costs, and increase public acceptance.

Results

CCAT has developed and refined resources to analyze potential sites for hydrogen and fuel cell deployment throughout the region. These models make available information for non-technical and technical audiences, including state and local decision makers and potential end users and will be an integral component of education and outreach efforts. The RRC models are described in Table 1.

Economic Impact

A study was conducted to examine the economic impact for each state of the Northeast Region. The economic impact was defined as the direct output, employment, and labor income associated with the 25 hydrogen and fuel cell original equipment manufacturers located in CT, MA, and NY, as well as the region-wide multiplier effects supported by the purchases of businesses and workers related to the industry (Figure 1).

Awareness

CCAT has also completed an assessment of the level of knowledge and opinions of hydrogen and fuel cell technologies of local and state stakeholders to determine the effectiveness of the project implementation. As shown in Figure 2, the results of the awareness survey suggest that there

TABLE 1. RRC Models and Descriptions

Model Type	Description
Environmental	Assesses the environmental benefits of hydrogen and fuel cell applications compared with other conventional technologies. The model can be used to assess potential emissions reductions, including greenhouse gases, using hydrogen and fuel cell technology.
Economic/Cost	Assesses potential yearly heating and electricity cost savings when using a commercially available fuel cell for baseload power. The model allows users to assess the economic viability of a fuel cell system.
Energy Management	Assesses the efficiency benefits of stationary fuel cell applications. The model can be used to assess the potential energy savings using a fuel cell to replace conventional electricity generating technologies.
Distributed Technology Comparison	Allows a user to compare fuel cells with other distributed energy technologies including microturbines, combustion turbines, reciprocating engines, photovoltaic systems, and wind turbines, based on certain criteria such as installation cost, efficiency, emissions, heat rate, etc.
Hydrogen Generation From Renewable Technology	Assesses wind, photovoltaic and hydroelectric power generation technologies to identify hydrogen production capacities and average cost per kilogram of generated hydrogen from these renewable technologies.

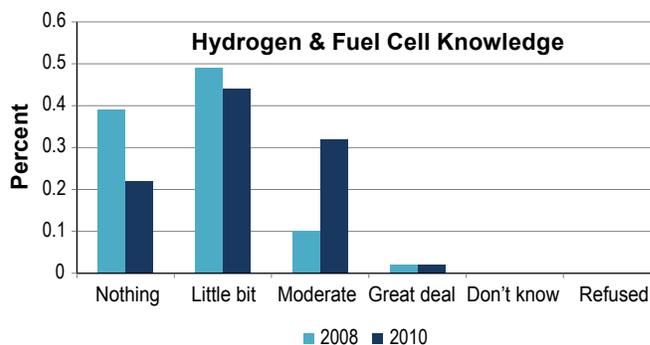

FIGURE 2. Level of Awareness

created to facilitate the education of decision makers and end users and to provide the ability to analyze potential sites for hydrogen and fuel cell technologies.

Next steps: CCAT will continue to build upon existing relationships and partnerships while creating new opportunities. Identified target locations for fuel cell deployment in the service areas based on energy intensive commercial building types identified by EPA's CBECS will be mapped by locations using ArcGIS software and included within the individual state guidance documents. In addition, CCAT will facilitate the dissemination of information to municipal decision makers and stakeholders, and keep state officials abreast of activities to deploy hydrogen and fuel cell technologies through the use of collaborative meetings and briefings to achieve state goals including energy reliability, security, efficiency, emissions and economic development. CCAT will also provide the information on financial and investment opportunities to encourage market growth, reduce costs, and increase public acceptance.

CCAT will continue its education and outreach efforts on the regional scale and continue to support the development of state roadmaps. These roadmaps should serve to effectively encourage and support the successful development and deployment of hydrogen and fuel cell projects in the New England, New York, and New Jersey regions.

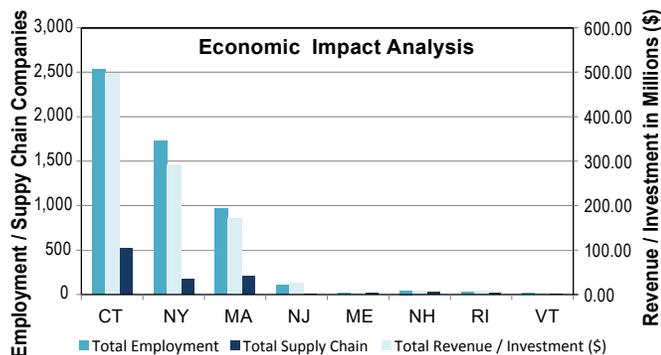

FIGURE 1. Economic Analysis Results

was an increase in level of knowledge regarding hydrogen and fuel cell technology, its application, costs, and benefits.

Conclusions and Future Directions

This partnership effort has successfully identified a process with stakeholder participants, created models and tools that will allow potential adapters to assess opportunities for deployment of hydrogen and fuel cell technologies in early market applications, and has been expanded to replicate the stakeholder process and tools to develop guideline “Roadmap” documents in each of the New England States, New York, and New Jersey. The process models and tools and guideline documents have been

Special Recognitions

2011 Annual Merit Review Awards

On May 11, 2011, DOE recognized CCAT for work on the advancement of fuel cell and hydrogen technologies for Connecticut and the Northeast. The award highlighted CCAT’s collaborative educational outreach efforts that span the Northeast with groups such as the Northeast Energy Commerce Association and the Northeast Sustainable Energy Association, the analysis of job growth and economic development impacts attributable to the fuel cell industry and its supply chain, and the development of models to help potential fuel cell customers evaluate the life-cycle costs and benefits of deploying fuel cells.

Contract Number: DE-FC3608GO18111 A000

Subcontractors:

- National Conference of State Legislatures, Denver, CO
- Dr. Timothy Lipman, University of California, Berkeley, Berkeley, CA

Project Start Date: September 1, 2008

Project End Date: August 31, 2011

Fuel Cell Technologies Program Multi-Year Research, Development and Demonstration Plan:

- **Milestone 17** in Task 3: Educate State and Local Government Representatives. (recurring annually, including 2011)
- **Milestone 19 in Task 4**: Educate Potential End-Users. (4Q, 2011)
- **Milestone 14 in Task 2**: Educate Local Communities. (recurring annually, including 2011)
- **Milestone 30 in Task 7**: Assess Knowledge and Opinions of Hydrogen Technologies. (4Q, 2012)

Accomplishments

- Produced report and briefing paper about hydrogen production and storage for distribution to state policymakers and others.
- Organized, publicized, hosted, and facilitated five webinars on hydrogen and fuel cell topics of interest to state policymakers, local leaders, and end users. For the last two webinars, more than 300 people registered, including many state policymakers. All webinar presentations and recordings are posted on the CESA website.
- Informed state legislators through joint activities with the National Conference of State Legislatures (NCSL), including a webinar, a presentation at the NCSL Fall Forum, and a *NCSL LegisBrief*, an *NCSL WebBrief*.
- Encouraged cooperation and collaboration among DOE state education grantees by organizing, hosting, and facilitating six monthly calls focused on information exchange and strategy discussions.
- Reached influential audiences—state policymakers, financial institutions, business leaders, end users, and others—by giving presentations and distributing several of CESA’s fuel cell briefing papers at conferences and meetings, including the CESA Fall 2010 Members Meeting, the NCSL Fall Forum, the Building Energy Conference, Fuel Cells Finance and Investment Summit, Ohio Fuel Cell Symposium, and the Northeast Commerce and Energy Association.

Fiscal Year (FY) 2011 Objectives

- Identify state hydrogen project best practices and policies.
- Develop strategies and information to overcome many state policymakers’ resistance to providing support for fuel cells.
- Provide information and technical assistance to state policymakers and state renewable energy programs to foster effective fuel cell programs.
- Promote strategic opportunities for states and DOE to advance fuel cell deployment through partnerships, collaboration, and targeted activities.

Technical Barriers

This project addresses the following technical barriers from the Education section (3.9.5) of the 2009 Fuel Cell Technologies Program Multi-Year Research, Development and Demonstration Plan:

- (A) Lack of Readily Available, Objective, and Technically Accurate Information
- (B) Mixed Messages
- (C) Disconnect between Hydrogen Information and Dissemination Networks

Contribution to Achievement of DOE Education Milestones

This project contributes to achievement of the following DOE milestones from the Education section of the 2009

Introduction

Over the past two decades, the states have played a crucial role in advancing various clean energy technologies by implementing supportive policies and providing financial incentives. The states have the potential to do much to speed fuel cell commercialization. However, relatively few states are currently targeting fuel cell installation or

deployment with incentives or support programs. This hesitance to support fuel cells stems, in part, from reductions in available state funding for clean energy, but can also be attributed to the opinion that other energy technologies will provide a larger return on investment.

This project seeks to encourage states to consider taking steps to advance fuel cells, particularly stationary applications. It does this by providing state policymakers with accurate, convenient, easily digestible information and by directly addressing specific fuel cell-related issues that are of most concern to state policymakers. CESA is an ideal organization to lead this project, because the members have an in-depth understanding of the perspective of state clean energy agencies and other state energy policymakers, and have had considerable success facilitating state collaboration

Approach

The foundation for CESA's work on this project is a solid understanding of the perspectives and needs of state policymakers. For that reason, we maintain ongoing contact with key state policymakers—both from states that are providing financial support for fuel cells and from those that are not—through interviews, informal group discussions, and monitoring of relevant developments at the state level. From this intelligence gathering, we have identified the specific reasons why state policymakers have not been taking more aggressive action to promote fuel cells. We have then crafted messages and materials designed to encourage action. Those messages are delivered through well-attended webinars, widely circulated briefing papers, conference presentations, a webpage (www.cleanenergystates.org/projects/hydrogen-and-fuel-cells) a project listserv, and other means. We emphasize case studies of model projects and the identification of targeted actions that can appeal to state policymakers.

We also make sure that our work is well coordinated with the work of other DOE state-related fuel cell grantees, by facilitating monthly conference calls and maintaining regular one-on-one contact with those grantees.

Results

Early in this project, we identified hydrogen production and storage as an important topic on which state policymakers needed education. Because many of them were unfamiliar with current fuel cell technology and current uses of hydrogen, they had concerns about hydrogen safety and whether there would be an adequate supply of hydrogen if stationary fuel cells start to be used more widely. To directly address those two concerns, we produced and disseminated a briefing paper and a more detailed report on the topic of hydrogen production and storage. The longer report was written by Timothy Lipman, researcher and lecturer at the University of California, Berkeley and

Director of the U.S. Department of Energy Pacific Region Clean Energy Application Center. The briefing paper, which is designed to provide policymakers with the most essential information in a user-friendly format, draws on the longer report. We also hosted a webinar during which Dr. Lipman discussed his findings.

Because states have limited funding for supporting fuel cells and agency staff members have limited band-width to devote to fuel cells, we believe it makes sense for them to focus on those few market niches and audiences where near-term progress can be easiest and most likely. We identified supermarkets as one such niche, because several supermarket chains were already experimenting with fuel cells with the help of state support and because some supermarkets have an energy load profile that enables them to efficiently use both the electricity and heat produced by fuel cells. Moreover, this is a market dominated by large chains which have the ability to become repeat fuel cell customers if they are satisfied with their first installations. We used a webinar, attended by approximately 250 people, to encourage the consideration of fuel cells for supermarkets.

Although only a few states currently allow natural gas-fueled fuel cells to qualify for their renewable portfolio standards (RPSs), our research suggests that other states could be open to making such fuel cells eligible for inclusion. Concerns about local economic development and baseload power, as well as the limitations that the Interstate Commerce Clause of the Constitution places on RPSs, could make natural gas fuel cells appealing to states. We therefore organized a webinar on the topic, attended by 263 people, and various policymakers responded favorably to the presentations. The coincidental announcement by officials in Delaware that they would try to expand their RPS to include fuel cells gave additional attention to this topic.

We believe that we have played a valuable role over the past year by encouraging and facilitating greater cooperation and collaboration among DOE's state-related fuel cell grantees. Starting in December 2010, we organized monthly conference calls that have gone beyond the sharing of updates and announcements to discussions about strategy-related topics, such as key messages, target audiences, and model practices. We have maintained regular contact with many of the grantees and have tried to help their efforts by providing them with information about state policies and promoting their publications and events to our mailing list. As an example, we recently helped Virginia Clean Cities organize a webinar about fuel cells and first responders and are hosting that webinar, because Virginia Clean Cities does not have the platform or resources to do so.

Our other outreach activities—including presentations at conferences, the distribution of materials, and website updates—have all served the purpose of educating state policymakers, local leaders, and end users about fuel cells.

Conclusions and Future Directions

The grant from DOE for this project ends on August 31, 2011. But, before then, we will carry out several activities that will extend the reach and impact of the project. We will:

- Produce a briefing paper on fuel cells for supermarkets, including case studies of several supermarket projects. This briefing paper will build upon the webinar on the same topic and place the most essential information into a user-friendly form.
- Send out a printed packet of all five of CESA's briefing papers to a mailing list of several hundred state energy officials plus key state legislators. We believe that they will find this packet to be convenient and useful, and delivering hard copies will increase the likelihood that they will read the material.
- Hold a webinar on the topic of new financing approaches for fuel cells, including leasing and power purchase agreements. We believe that the increasing use of these financing models can make support for fuel cells more appealing to state policymakers.
- Hold a discussion with relevant state policymakers and others (e.g., representatives of Pacific Northwest National Laboratory) on the topic of performance monitoring of fuel cells. This discussion will enable them to share information on their individual performance monitoring approaches and to consider how they can cooperate on joint efforts.
- Continue ongoing activities, including disseminating information through the CESA fuel cell website and listserv and hosting monthly calls of DOE grantees.

Our efforts over the past year have significantly increased our understanding of state policymakers' views and needs related to fuel cells. We then identified and carried out focused activities that are helping to move state fuel cell efforts forward. CESA is well placed to encourage states to undertake further concrete market transformation actions related to stationary fuel cells, especially in regard to fuel cell financing, RPSs, supermarkets, and performance monitoring. However, additional funding would be required to allow us to devote significant attention to those topics after August.

FY 2011 Publications/Presentations

1. Presentation: Presenter at "Hydrogen & Fuel Cell Activities Regional Briefing," Northeast Energy and Commerce Association, Westborough, MA. (July 22, 2010).
2. Publication: "Hydrogen Fuel Cells: On-Site Energy Generation," *NCSL LegisBrief* (August-September 2010). Available at www.ncsl.org/default.aspx?tabid=21094.

Subcontractor:
Scott Greenway, Greenway Energy, Aiken, SC

Project Start Date: October 1, 2008
Project End Date: July 31, 2011

- (E) Regional Differences
- (F) Difficulty of Measuring Success

Contribution to Achievement of DOE Education Milestones

This project will contribute to achievement of the following DOE milestones from the Education (3.9) section of the 2009 Fuel Cell Technologies Program Multi-Year Research, Development and Demonstration Plan:

- **Milestone 11:** Develop set of introductory materials suitable for a non-technical audience. (4Q, 2006)
- **Milestone 13:** Develop materials for community seminars. (4Q, 2008)
- **Milestone 14:** Hold community seminars to introduce local residents to hydrogen. (4Q, 2008 through 4Q, 2012)
- **Milestone 17:** Hold "Hydrogen 101" seminars. (4Q, 2008 through 4Q, 2012)
- **Milestone 29:** Evaluate knowledge and opinion of hydrogen technology of key target audiences and progress toward meeting objectives. (4Q, 2009)

Fiscal Year (FY) 2011 Objectives

- Synthesize objective and technically accurate information that will be made available to a wide audience through the Internet, a national meeting, and training sessions.
- Design and develop educational programs that will clarify the benefits and challenges of developing a hydrogen infrastructure and avoid over-selling hydrogen technologies.
- Leverage relationships with project team organizations in South Carolina to distribute hydrogen education materials to government and code officials.
- Train a group of hydrogen educators at the project team institutions (the South Carolina [SC] Energy Office, the state fire marshal's office, the SCHFCA and Greenway Energy) who will be resources to the target audiences.

Technical Barriers

This project addresses the following technical barriers from the Education section (3.9.5) of the 2009 Fuel Cell Technologies Program Multi-Year Research, Development and Demonstration Plan:

- (A) Lack of Readily Available, Objective, and Technically Accurate Information
- (B) Mixed Messages
- (C) Disconnect Between Hydrogen Information and Dissemination Networks
- (D) Lack of Educated Trainers and Training Opportunities

FY 2011 Accomplishments

- In person presentations to over 30 groups of targeted South Carolina decision makers.
- Held three webinars to provide information to stakeholders throughout South Carolina.
- Reached 1,744 targeted additional state and local government officials and decision makers.
- Webinar presentations can be viewed through a SlideShare channel.
- Videos of educational information on hydrogen are available on the SCHFCA YouTube channel.
- Developed case studies on early markets for hydrogen and fuel cell technologies including: fuel cell lift trucks, combined heat and power, and telecommunications backup power.
- Presentations to groups including the National Congressional Candidates, Gubernatorial Candidates, State House and Senate Candidates, Head of the South Carolina Department of Commerce, Agency heads at the South Carolina Department of Health and Environmental Control.
- Hydrogen 101 materials were utilized in wider public education efforts that reached additional non-decision makers.
- Educational efforts with South Carolina House and Senate members to demonstrate the effect of state level incentives for fuel cells and renewable technologies on creating viable markets.

Introduction

Hydrogen and fuel cell technologies are moving out of the laboratory and into economically competitive niche markets such as cell phone tower backup power and forklift operations. As hydrogen technologies become competitive in these early markets, communities will need to be educated about the opportunities afforded by hydrogen technologies and about safety concerns associated with them. The Hydrogen 101 program led by the SCHFCA seeks to raise awareness about hydrogen and fuel cells to community leaders within SC and the southeast.

SC is among a small, but growing, number of states that have a hydrogen implementation strategy and is on the leading edge of fuel cell research and adoption. The state has been recognized as one of the top five leaders in hydrogen and fuel cells, but a significant lack of information on hydrogen still exists among state and local leaders. In order to maximize the resources existing in the state and surrounding region, it is imperative that an effective outreach and education program be conducted so that the decision to accept hydrogen technologies in the local community is informed and wise.

Approach

The project team is composed of SC-based hydrogen experts with connections to technically accurate information; and, civic organizations and associations with the communications networks and events with our target audience already established. The entire team works together to identify specific messaging that the local audience and sub audiences are interested in. Based on the feedback we gather from the civic organizations and other community opinion leaders, education materials and demonstrations are developed.

The marketing of the program is conducted through the existing websites, e-mail distribution lists and communication networks. The distribution of the material is primarily conducted at events associated with each of the civic associations partnering on the project, however, several stand-alone events and webinars are planned.

Results

Building on the educational successes that assisted in the passage of the South Carolina Hydrogen Permitting Act, SCHFCA has focused its attention on renewing relationships with decision makers in FY 2011 and reaching out to new candidates to in state and national political offices. These efforts have been focused on discussing the success of hydrogen and fuel cell technologies in early markets and methods to increase adoption of hydrogen technologies within the state and region.

In 2011 the Hydrogen 101 program expanded its audience to include business leaders and economic development officials based on input gathered from stakeholders. The focus of interactions with decision makers has focused on emphasizing the business case for fuel cells in early markets. This education focuses on helping them understand where fuel cells can provide a value proposition for their organizations. The program performed outreach to these groups through presentations and small or individual meetings. Presentation materials were updated and expanded depending on the audience and brochures were printed to summarize key messages.

The SCHFCA Hydrogen 101 program far exceeded its goals of 3 webinars and 30 in-person presentations. The number of direct stakeholders reached was 1,744 and the wider educational efforts that leveraged Hydrogen 101 materials reached over 2 million people. In addition to the education of leadership groups, the SCHFCA contacted candidates for political offices who will be filling vacated offices in 2011 and has continued discussions with newly elected leaders. The educational efforts focused on helping them understand how the hydrogen and fuel cell industry is growing the state economy, creating high paying jobs, and saving businesses money.

Groups have been overwhelmingly supportive of hydrogen and fuel cell technologies as a result of the presentations and view the technologies as having the potential to foster economic development within the state. Work has been started to collaborate with other states including Tennessee, North Carolina, and Florida. These collaborations will help educate regional leaders about opportunities for a hydrogen technologies in their state and the potential to grow an interconnected regional hydrogen infrastructure.

Conclusions and Future Directions

The SCHFCA Hydrogen 101 program has met all of its goals and its efforts are having an impact on the wider support of hydrogen. Education about the effect of state level incentives on the market for fuel cell and other renewable technologies has started to show how states can grow their hydrogen infrastructure. In 2012, educational efforts will focus on presenting the value proposition for fuel cell systems to stakeholders and working to develop a more regional approach to hydrogen and fuel cell industry growth. The project will use a mixture of webinars, in-person presentations, and electronically available resources to train decision makers.

IX.5 VA-MD-DC Hydrogen Education for Decision Makers

Chelsea Jenkins

Virginia Clean Cities (VCC)

Contract Number: DE-FG36-08GO18115

Subcontractors:

- Catherine E. Grégoire Padró, Los Alamos National Laboratory, Los Alamos, NM
- Greg Jackson and Peter B. Sunderland, University of Maryland (UM), College Park, MD
- Christopher Bachmann, James Madison University (JMU), Harrisonburg, VA

Project Start Date: September 1, 2008

Project End Date: September 30, 2011

Fiscal Year (FY) 2011 Objectives

The goal of this three-year project is to increase the targeted audience's understanding of hydrogen and fuel cells, including early market applications, and to provide specific examples of actions that state and local government leaders can take to support the development and use of hydrogen and fuel cell technology leading to better understanding of community benefits. The main objectives of the two-year project are to:

- Conduct a dozen workshops by technical experts and professional educators.
- Produce video resources for public television, seminar use, DOE, and the general public.
- Use hardware demonstrations when possible and provide real-world examples of technology.
- Produce electronic "magazine" articles on hydrogen and fuel cell technology demonstrations and other instructional project deliverables.

Technical Barriers

This project addresses the following technical barriers from the Education section (3.9) of the 2009 Fuel Cell Technologies Program Multi-Year Research, Development and Demonstration Plan:

- (A) Lack of Readily Available, Objective, and Technically Accurate Information
- (B) Mixed Messages
- (C) Disconnect between Hydrogen Information and Dissemination Networks
- (D) Lack of Educated Trainers and Training Opportunities
- (F) Difficulty in Measuring Success

Contribution to Achievement of DOE Education Milestones

This project will contribute to achievement of the following DOE milestones from the Education Technical Plan (3.9) section of the 2009 Fuel Cell Technologies Program Multi-Year Research, Development and Demonstration Plan:

- **Milestone 17:** Hold "Hydrogen 101" seminars. (4Q 2008 through 4Q, 2011)

FY 2011 Accomplishments

The following has been accomplished during FY 2011:

- Maintained key partnerships with over 30 different public and private organizations in Virginia, Washington, D.C., and Maryland to promote program and message.
- Conducted four "Hydrogen 101" seminars in Virginia, Washington D.C., and Maryland.
- Aired Motorweek "Hydrogen and Fuel Cells Emerging Markets" video and developed Y3 "Vehicles and Infrastructure Update" video.
- Developed and updated website and social media tools (Facebook, YouTube, Twitter).
- Held ride-n-drives of Equinox Fuel Cell Electric at three events.
- Published quarterly newsletters.
- Developed first responders webinar workshop.
- Implemented surveys at two workshops.
- Completed fuel cell scooter demo with James Madison University Alternative Fuel Vehicle Lab and showcased at two events.

Introduction

In order to change the way we use energy and to increase the deployment of hydrogen and fuel cell technologies, decision makers will need to make informed

public policy decisions and continue to support research and development as well as deployment activities. This project aims to raise awareness of hydrogen and fuel cell technologies, provide examples of what state and local government can do, and show how decision makers can support the development and use of hydrogen and fuel cell technologies.

The objectives of this project are to provide hydrogen and fuel cell technology learning opportunities through seminars, multi-media, and video resources, and to provide technical support and demonstrations to local and state government and decision makers. These activities will help leaders become familiar with hydrogen and how it fits into the portfolio of near-term and long-term energy choices, develop an accurate understanding of hydrogen safety, recognize opportunities, and understand their part in facilitating use of hydrogen and fuel cell technologies.

Approach

Our primary approach is to host in-person and webcast seminars for our target market. Messaging ties to the hydrogen knowledge survey, on which the subprogram objectives and targets are based. Under DOE guidance, existing Education sub-program resources and new contributions by team members are considered. Educational content focuses primarily on a basic understanding of hydrogen properties and the energy security and environmental benefits of hydrogen and fuel cell technologies, but also focuses on more technical subjects related to fuel cells and other modes of hydrogen energy conversion. Special consideration has been given to “following the technology” and resources also concentrate on areas where hydrogen and fuel cells are publicly visible through demonstration projects or early niche market commercialization efforts, such as hydrogen fuel cell forklift program at the Defense Distribution Depot Susquehanna, Pennsylvania, and fuel cell installations at Gills Onions and Sierra Nevada Brewery in California.

The key to state and local government representative education is a broad understanding of how hydrogen supports decision-making on current opportunities and how to lay the foundation for long-term change. Additionally, providing real-world examples and demonstrations has been a key component of each seminar.

Results

The major achievements over the last year include hosting four successful, and highly received events completing a shooting schedule and beginning production of a third seven-minute video for seminar use and broadcasting on PBS and Discovery HD Theatre developing webinar curriculum and developing, completing, and showcasing a university student senior thesis deployment project.

Seminar Results

The curriculum prepared and presented by Dr’s Chris Bachmann, Dr. Peter Sunderland, and Dr. Greg Jackson at workshops in Harrisonburg, Virginia, and College Park, Maryland included:

- Overview of the current energy system
- What is hydrogen and what is a fuel cell?
- Hydrogen production, storage, distribution, and use
- Environmental, energy and economic implications of fuel cells and hydrogen
- Safety, codes and standards
- The future of hydrogen and fuel cells

Ride and drive events were held along with a screening of the “Emerging Markets” MotorWeek video. The JMU event also featured presentations by Hampton Roads Hydrogen, Marz Industries, and the JMU AFV demo team. Also, at both of these seminars, a post-workshop survey was distributed to assess the usefulness of each workshop component. The results of these surveys are provided in Table 1. Two additional events were held in conjunction with the presentation of senior thesis projects at James Madison University and as part of a general Fleet Innovation Seminar held at the Fairfax County government center in Fairfax, Virginia. The JMU event featured a “Hydrogen 101” presentation and a presentation highlighting the development and features of the Alternative Fuel Vehicle Lab scooter. Dr. Greg Jackson contributed a “Hydrogen 101” presentation at VCC’s Fleet Innovation Seminar in addition to a Fuel Cell Equinox Ride and Drive.

Why did you attend today's seminar?		
<ul style="list-style-type: none"> To contribute and learn. To learn more about the state of the science of creating environmentally friendly hydrogen. To see what the current status of hydrogen power is. Get more information about hydrogen, it's use, and applications. Interested in hydrogen production technologies. To become informed. To see student presentations. Learn more about advancements in development of hydrogen as an energy source. Learn about fuel cells and stations in VA. Knowledge of alternative energy source. Interest in and concern about our energy policy as it affects our economy and investments. General interest in renewable energy options. Learn about hazards and safety involving fuel cells. We are considering alternate fuel vehicles. Improve knowledge of hydrogen characteristics, use, and safety issues. Support Clean Cities mission and interested in fuel cells. Learn more about current state of fuel cell technology, especially as it relates to transportation, including current Administration support and potential involvement of state agencies. 		
What was the most interesting part of today's seminar?		
<ul style="list-style-type: none"> Multiple sources of info. Discussion of stationary applications. Vehicles running on hydrogen using combustion engines. Discussion of variety of applications. Emerging applications. Who is using fuel cells. How long fuel cells have been in use as fuel/energy provider. Production and storage info. Stationary applications. Characteristics of hydrogen and impact on fire safety. General operation and components of fuel cell systems. 		
What did we NOT cover today that you desired? How can we improve?		
<ul style="list-style-type: none"> Small hydrogen generator systems using solar power. Have flyer with local, regional, and national avenues with grant funding/assistance with trying to implement hydrogen facilities within government. More on economics, where are we going and how fast? More technical information regarding cutting edge research. 		
Other comments?		
<ul style="list-style-type: none"> Dr. Bachmann did a great job. Excellence coverage and balance of topics. Schedule event for fire fighters and fire safety personnel. 		

MotorWeek "Emerging Markets" Video

Virginia Clean Cities and the DOE worked with MotorWeek to produce and air a video entitled "Emerging Markets." In addition to footage of many fuel cell electric vehicles and early market applications at the 2010 National Hydrogen Association conference, footage also included interviews with leaders of hydrogen and fuel cell focused organizations and industry leaders who have implemented fuel cells. The video is approximately seven minutes and includes an overview of hydrogen and fuel cell applications that are in use presently.

MotorWeek "Vehicles and Infrastructure Update" Video

This video will highlight progress made in fuel cell electric vehicle design and use, as well as advances in infrastructure towards the planned release. Footage will include video of several vehicles and General Motor's newest fuel cell engine, along with video of various fueling installations.

Conclusions and Future Directions

The seminars that have been held to date have been very well received and the participants' knowledge of hydrogen and fuel cell technology has increased as indicated by the surveys. At least two more events/outreach projects targeted at decision makers will be carried out in the remainder of the project period. This project will end in September 2011.

Future Project Outputs

- Complete outreach efforts including First Responders Webinar.
- Complete production and airing of third MotorWeek video focusing on vehicles.

Planning and Improvements

After surveying several targeted individuals, it was confirmed that travel restrictions and time constraints have affected our ability to attract participants at in-person workshops. It is our hope that events such as the upcoming first responders webinar and other targeted outreach activities will address this issue.

Key Issues

The project's main issue is that current participants and the target audience in general are being assigned extra demands and do not have time to take part in the seminars and webinars.

FY 2011 Publications/Presentations

- Greg Jackson PowerPoint for 3/11 and 3/23 seminars.

2. Peter Sunderland PowerPoint for 3/11 seminar.
3. Chris Bachmann PowerPoint for 2/25 seminar.
4. PowerPoint for 6/11 Annual Merit Review oral presentation.
5. Student presentations of hydrogen demo thesis project.
6. MotorWeek “Emerging Markets” video.

All presentations available at <http://www.hrccc.org/cleaner-transportation-options/hydrogen/hydrogen-seminars/>

IX.6 H2L3: Hydrogen Learning for Local Leaders

Patrick Serfass

Technology Transition Corporation
1211 Connecticut Ave., NW Suite 600
Washington, D.C. 20036
Phone: (202) 457-0868
E-mail: pserfass@ttcorp.com

DOE Manager

GO: Greg Kleen
Phone: (720) 356-1672
E-mail: Greg.Kleen@go.doe.gov

Contract Number: GO18114

Subcontractors:

- Public Technology Institute (PTI), Washington, D.C.
- Schatz Energy Research Center, Humboldt State University, Arcata, CA

Project Start Date: October 2008

Project End Date: August 2011

(D) Lack of Educated Trainers and Training Opportunities

Contribution to Achievement of DOE Education Milestones

The H2L3 project will directly address the following milestones of the Education sub-program:

- **17:** Hold “Hydrogen 101” seminars. (4Q, 2008 through 4Q, 2012)
- **18:** Develop end-user workshop materials for use at events. (4Q, 2009)
- **30:** Evaluate knowledge and opinion of hydrogen technology of key target audiences and progress toward meeting objectives. (4Q, 2012)

The H2L3 project directly contributes to achieving these milestones by conducting education workshops with hundreds of local and state officials from across the country and by training motivated local officials to replicate the workshops in their own communities. By fostering and using the H2L3 team’s existing network of national associations of local and state government officials, the reach and the credibility of the outreach will be substantially and uniquely strengthened. This network will continue to support the goals of the DOE beyond the three-year life of this project by establishing institutional relationships that will enable on-going and expanding opportunities for hydrogen and fuel cells outreach through the national associations representing local and state officials.

Fiscal Year (FY) 2011 Objectives

- Create presentation materials tailored to effectively communicate with state and local government leaders. Relate hydrogen to their interests and spheres of responsibility.
- Establish pathways for working with national associations of state and local officials as a route for disseminating information about hydrogen. Set pattern for on-going information flow.
- Launch learning sessions by conducting initial workshops for local and state officials at national gatherings. Achieve nationwide reach.
- Provide market analysis around the fuel cell infrastructure. The report produced will establish an improved understanding of the current state of production, distribution, storage, and the use of hydrogen, which is a critical fuel for the fuel cell industry.

Technical Barriers

This project addresses the following technical barriers from the Education section of the 2009 Fuel Cell Technologies Program Multi-Year Research, Development and Demonstration Plan:

- (A) Lack of Readily Available, Objective, and Technically Accurate Information
- (B) Mixed Messages
- (C) Disconnect Between Hydrogen Information and Dissemination Networks

FY 2011 Accomplishments

- Core Curriculum
 - Comprehensive, basic presentation developed to communicate with state and local officials.
 - Curriculum trimmed or modified for specific audiences as needed.
- Advisory Committee of Local and State Officials
 - Established an advisory committee comprised of Public Technology Institute members (local) and National Association of State Energy Officials members (state) to review the curriculum and provide input.
- Peer Presenters
 - Identified four different peer presenters who have been or will be utilized to help spread the information in the curriculum to other local leaders.
- Hydrogen 101 Workshops
 - Held three workshops at annual national meetings of the Public Technology Institute and National Association of State Energy Officials.

- Reached over 100 local leaders who have been individually identified, 700+ counted and several thousand reached so far (radio and online) with educational materials.
- U.S. Market Report: Hydrogen and Fuel Cells
 - Completed research covering 57 different sectors of the hydrogen and fuel cell industries.
 - Peer reviewed, endorsed by the National Hydrogen Association (NHA), published www.hydrogenassociation.org/marketreport.
 - Over 70,000 downloads of the report so far.
 - Data and charts used by DOE in annual reports and presentations.
- Hydrogen Learning for Local Leaders Breakfast at NHA Conference with the California Fuel Cell Partnership
 - Informal networking breakfast targeted to southern California local leaders.
 - Used an unconventional, non-presentation-based approach by mingling experts with local leaders to create intimate conversations.
 - Very successful. Allowed questions to emerge organically and multiple future opportunities.
- Hydrogen Business Solutions Forum at the NHA Conference
 - Peer-to-peer series of presentations presented by current users of fuel cells for current and potential users of fuel cells.
 - www.hydrogenconference.org/h2fcForum.asp
- 2010 Hydrogen Student Design Contest
 - Challenged teams of university students from around the world to plan and design the basic elements of a hydrogen community in Santa Monica, CA.
 - Thirty-two teams registered, 12 submitted designs from four countries: United States, Canada, Bangladesh, Ukraine.
 - Three winning teams presented designs at NHA Hydrogen Conference and Expo in Long Beach, California; Grand Prize: Missouri University of Science and Technology; Honorable Mentions: University of Waterloo and the National University of Kyiv (Ukraine).
 - Grand-prize winning team presented at the World Hydrogen Energy Conference in Essen, Germany.
- 2011 Hydrogen Student Design Contest
 - Challenged teams of university students from around the world to plan and design a residential hydrogen fueling system.
 - Fifty-four registered universities (a new record) from 19 countries, including seven of the top 20 engineering schools in the world.
- Grand Prize: University of Waterloo (5-time winner); Honorable Mentions: Imperial College London, University of California, Riverside.
- Eighty-nine percent of survey respondents say they would participate in the contest again; other 11% would consider, depending on theme.

Introduction

Increasing education about hydrogen and fuel cells is key to enable widespread commercialization. This project began with the goal of educating local leaders. As the project progressed, tactics broadened to include additional paths to local leaders and new audiences to provide educational and information tools that increase knowledge about hydrogen and fuel cells.

Approach

Activities include Hydrogen 101 in-person presentations, webinars, the creation of a market report that features industry data not published before, the creation of a business solution forum for existing and potential hydrogen customers, and a student contest to engage university students to design a hydrogen community in southern California.

Going forward, the approach will include a series of webinars. The electronic format should allow us to reach more local leaders with reduced cost to allow the remaining resources to be stretched further

Results

Following is a summary of select results:

Partnered with the Public Technology Institute and the National Association of State Energy Officials to provide Hydrogen 101 presentations. Local leaders have been engaged from the following areas:

- Cincinnati Health Department
- City of Boston Environment Department
- City of Carlsbad, California
- City of Cincinnati, Ohio
- City of Culver, California
- City of Dayton, Ohio
- City of Des Moines, Iowa
- City of Fort Wayne, Indiana
- City of Fort Worth, Texas
- City of North Kingstown, Rhode Island
- City of Orlando, Florida
- City of Phoenix, Arizona

- City of San Diego, California
- City of Santa Monica, California
- City of South Sioux City, Nevada
- City of Wilmington, North Carolina
- City of Winston-Salem, North Carolina
- Washington, D.C.
- Fairfax County Dept. of Vehicle Services, Virginia
- Los Angeles County, California
- Regional Governmental Services of California
- San Diego County, California

Feedback from attendees Hydrogen 101:

- “Very understandable.”
- “For the first time, I understood what hydrogen is.”
- “This was really good.”
- “Really informative.”
- “Showing the number of fueling stations made it real. I thought hydrogen was more of an impossibility before.”

The U.S. Market Report: Hydrogen and Fuel Cells includes 57 different research areas. The full report and eight-point brief (see Figure 1) can be viewed and downloaded from: <http://tcorp.com/2011/pdf/marketReport.pdf>. The report has become the most popular download on the NHA Web site and has been downloaded over 70,000 times to date.

Accolades for the U.S. Market Report: Hydrogen and Fuel Cells

- It’s outstanding and will be a very useful resource for the community. NHA should be proud to put our logo on your work.... Thanks for the chance to review this impressive document. –Ken Schultz, Operations Director, Energy Group, General Atomics.
- Lot of great data. I had no idea that there are so many renewable projects. –Sandy Thomas, former President, H2Gen Innovations.
- A really good report. I think the front sections will make a great reference tool on the hydrogen industry generally and I already learned a few things!-Lisa Calaghan Jerram, Fuel Cell Today.
- This is an excellent report. I think it is very useful.- Dr. Finis H. Southworth, Chief Technology Officer, AREVA NP Inc.
- I am working on a hydrogen study for the University of Colorado and the Reliability and Sustainability Energy Institute (RASEI). Your US Market report on Hydrogen is great.
- Excellent reports - some of the most salient data & information out there, and very well presented.–From Randy Cole, CEO at Renewable Opportunities, Inc, via LinkedIn.

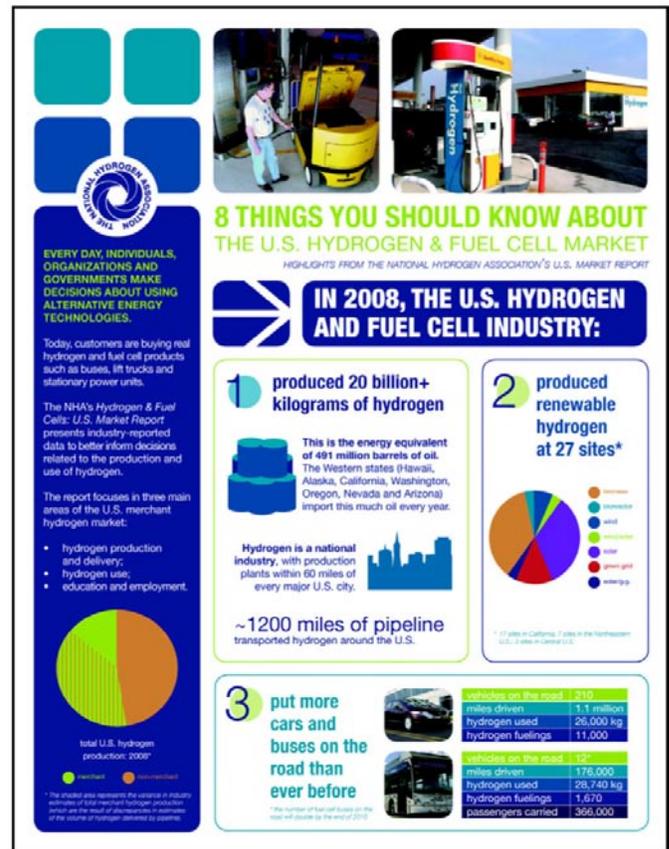

FIGURE 1. The 8-point brief of the U.S. Market Report: Hydrogen and Fuel Cells <http://www.tcorp.com/marketReport/brief.pdf>

- Love the 8-point brief. Succinct and direct. Thanks for drawing our attention to it. - Tom Sperrey, Chief Executive Officer (CEO), UPS Systems plc, via LinkedIn.
- The brief version is my kind of report! The full version looks very useful; many thanks for sharing the link. - Graham Cooley, CEO at ITM Power Plc, via LinkedIn.
- Very well done and very much needed! -Bay Elliott, EVP, Partner, Executive Recruiter, The Farwell Group, via LinkedIn.
- Is it possible to obtain a copy of your report in a non-pdf format? I would like to utilize some of the graphs and figures regarding H2 Energy in an internal slide presentation. If not the whole study, specifically pages 26-37. –from an industrial gas supplier (obviously a significant compliment if they’re happy using this information internally).
- These are very nice reports. I circulated them within Proton. –Mark Schiller, Vice President of Business Development, Proton Energy Systems.
- You and your team did an excellent job. Congratulations! - Patricia Irving, Ph.D., President & CEO, InnovaTek, Inc.
- This looks really, really nice. Thank you. I’ve started teaching the graduate course at Wayne State University

in alternative energy, and I plan to share this report with my class, as well as working it into my thinking about price and market position. Thank you again, and good luck with your work. - Robert Buxbaum, President, REB Research & Consulting.

The 2010 Hydrogen Student Design Contest challenged teams of university students from around the world to plan and design the basic elements of a hydrogen community in Santa Monica, California. They were asked to design one scalable hydrogen fueling station; identify renewable hydrogen sources in the community; and identify customers for early market hydrogen applications.

University teams from the United States, Canada, Bangladesh, and the Ukraine submitted contest entries. These entries were evaluated across ten different categories by a team of judges from government and industry.

The team from Missouri University of Science and Technology was declared the Grand Prize winner (see team photo, Figure 2). Teams from the University of Waterloo and the National University of Kyiv received Honorable Mention awards. Winning designs can be viewed at www.HydrogenContest.org.

The 2011 Hydrogen Student Design Contest challenged teams of university students from around the world students to plan and design a residential hydrogen fueling system. As a part of their entry, teams developed a technical design; conducted an economic analysis; and developed business, marketing, and public education plans for their systems.

University teams from 19 countries and seven of the top 20 engineering schools in the world competed. These entries were evaluated across ten different categories by a team of judges from government and industry.

The team from the University of Waterloo was declared the Grand Prize winner. This Grand Prize marks the fifth award for the University of Waterloo in the six-year history of

FIGURE 2. The Hydrogen Student Design Contest's 2009-10 grand-prize winning team: Missouri University of Science and Technology, <http://www.hydrogencontest.org/>.

the Contest (see team photo, Figure 3). Contest newcomers Imperial College London and University of California, Riverside were awarded honorable mentions. The 2011 Contest was sponsored by the U.S. Department of Energy, Praxair, Honda, and Proton Energy Systems. Winning designs can be viewed at www.HydrogenContest.org.

Conclusions and Future Directions

The feedback we have received about this project has been overwhelmingly positive. Where improvements have been suggested, adjustments have been made to improve the experience for any audience. Going forward, we recommend continuation of the Hydrogen 101 presentations using a webinar format, an expansion of the Market Report to include the next year's data to show trends (reinforced by at least one reviewer at the Annual Merit Review) and future Hydrogen Student Design Contests.

FY 2011 Publications/Presentations

1. NCSL short Hydrogen Overview for states, October 2010, <http://www.ncsl.org/?tabid=21289>.

Project Start Date: March 2009

Project End Date: June 30, 2012

- **Milestone 11:** Develop set of introductory materials suitable for a non-technical audience (3Q, 2009)
- **Milestone 13:** Develop material for community seminars (ongoing)
- **Milestone 16:** Develop database of state activities (ongoing)
- **Milestone 17:** Hold “Hydrogen 101” seminars (3Q, 2009 through 2Q, 2012)

FY 2011 Accomplishments

- July 13, 2010 – Ohio Fuel Cell Coalition Board Meeting - Dublin, Ohio – 45 people
- July 14, 2010 – China Export Commission - Toledo, Ohio - 15 people
- July 22, 2010 – Cleveland, Ohio – 40 people
- August 7, 2010 – Akron, Ohio – 25 people
- August 26, 2010 – Columbus, Ohio – 100 people
- September 16, 2010 – Canton, Ohio – 25 people
- September 30, 2010 – Dublin, Entrepreneur Center Presentation - Dublin, Ohio – 50 people
- October 18- 21, 2010 – Annual Fuel Cell Seminar - San Antonio, Texas – 25 people
- October 26, 2010 – Youngstown, Ohio – 35 people
- November 2, 2010 – Presentation at First Energy - Eastlake, Ohio – 50 people
- November 23, 2010 – Regional Economic Development Forum - Mansfield, Ohio – 35 people
- December 2, 2010 – Kent, Ohio – 20 people
- December 20, 2010 – IAB Board Meeting - Canton, Ohio – 10 people
- January 7, 2011 – Cincinnati, Ohio – 10 people
- January 25, 2011 – Ohio Fuel Cell Coalition Board Meeting - Logan, Ohio – 20 people
- February 15, 2011 – Ohio Fuel Cell Members Forum - Washington, DC – 20 people
- March 1, 2011 – Dayton, Ohio – 20 people
- March 23, 2011 – Kent City Leadership - Kent, Ohio – 20 people
- April 18 & 19, 2011 – North Canton, Ohio – Ohio Fuel Cell Symposium – 210 people
- April 26, 2011 – Wayne County Chamber - Orville, Ohio – 10 people
- May 21, 2011 – Ohio Society of Professional Engineers - Cleveland, Ohio – 50 people
- June 7, 2011 – Regional Leadership Forum - Lima, Ohio – 50 people
- June 8, 2011 – Northwest Ohio Leadership Forum - Perrysburg, Ohio – 30 people

Fiscal Year (FY) 2011 Objectives

- Increase understanding of hydrogen and fuel cell technologies among state and local governments by 10% compared to 2004 baseline.
- Increase knowledge of hydrogen and fuel cell technologies among key target populations (state and local governments) by 20 percent compared to 2004 baseline.

Technical Barriers

This project addresses the following technical barriers from the Education section of the Fuel Cell Technologies Program Multiyear Research Development and Demonstration Plan:

- (A) Lack of Readily Available, Objective and Technical Accurate Information
- (B) Mixed Messages
- (C) Disconnect Between Hydrogen Information and Dissemination Networks
- (D) Lack of Educated Trainers and Training Opportunities
- (E) Regional Differences
- (F) Difficulty of Measuring Success

Contribution to Achievement of DOE Education Milestones

This project will contribute to the following DOE Milestones from the Education section of the Fuel Cell Technologies Program Multiyear Research Development and Demonstration Plan.

The Ohio Fuel Cell Coalition was tasked with raising the awareness and understanding of Fuel Cells and the Hydrogen economy. In 2010 through 2011 the Ohio Fuel Cell Coalition held 23 community leaders forums. An annual community leader's forum was held in conjunction with the 2011 Ohio Fuel Cell Symposium. On April 18 and 19 over 210 people gathered at the Kent State Stark Campus for the 2011 Ohio Fuel Cell Symposium, the theme this year was Economic Opportunities Through the Fuel Cell Supply Chain. The symposium presented by the Ohio Fuel Cell Coalition began with two USDOE Community Leaders forum where participants had an opportunity to learn about Fuel Cells and the Hydrogen Economy. On Day 2 of the symposium the audience heard from a series of fuel cell integrators and fuel cell leaders, on the importance of the supply chain in fuel cell development. In the morning of the first day we heard from Mark Fleiner of Rolls-Royce Fuel Cell Systems and John O'Donnell, President of Stark State College of Technology discussed the emerging fuel cell clusters in North Canton, Ohio. A panel discussion was held in the afternoon with Steve Sinsabaugh, Lockheed Martin; Tim Lowe, Vice President of Sales of Energy Technologies and Vince Contini from Battelle who discussed Ohio's strength in the fuel cell genset arena. This event allowed the Coalition to educate over 210 individuals on fuel cells and the hydrogen economy which exceeded our expectations.

Approach

The approach we used and will be using for all the Community Leaders Forums will be presentations by the Ohio Fuel Cell Coalition in conjunction with regional leaders. The presentations will be followed by question and answers periods followed up by informal discussions on fuel cells and the hydrogen economy.

Results

In summary, the Community Leader Forums have been very successful in the last year with over 915 people being drawn to them. As always we followed up the forums with a survey and the survey results were very positive in that the participants had a significant increase in knowledge and awareness of fuel cells and the hydrogen economy.

Conclusions and Future Directions

We have received additional input on the Community Leaders Forums and we continued to add input to future events. The following Community Leader Forums will be held in the next three months:

- Cincinnati, Ohio
- Toledo, Ohio
- Athens, Ohio
- Cleveland, Ohio
- Akron, Ohio

IX.8 Dedicated to the Continued Education, Training and Demonstration of PEM Fuel Cell-Powered Lift Trucks in Real World Applications

Subcontractor:

Hydrogenics, Mississauga, Ontario, Canada

Project Start Date: September 1, 2008

Project End Date: August 31, 2011

- Infrastructure/Cost Justification
- Difficulty in Measuring Success

Contribution to Achievement of DOE Education Milestones

This project has and will continue to contribute to achievement of the following DOE milestones from the Education section of the Fuel Cell Technologies Multi-Year Research, Development and Demonstration Plan:

- **Milestone 1:** Developed “Awareness- Level” information for first responders (3Q, 2010). This work continued during the LiftOne Program’s 6th and final fuel cell-powered lift truck deployment at AGI in Forest City, NC - through the active participation of the local Forest City Fire Department at the H2 Orientation/ Safety Training sessions.
- **Milestone 14:** Hold Community Seminars to introduce local segments of those communities to hydrogen (3Q, 2010, 4Q 2009, 1Q 2010). Handled through participation and “Live” fuel cell-powered lift truck demonstrations at regional business events such as the “Green Is Good For Business Expo” - Columbia, SC (9/14/2010); Odyssey Week Events in Columbia, SC (10/11/2010), and Charlotte, NC (10/14/2010) (Figure 1).
- **Milestone 18:** Develop end-user workshop materials for use at events (3Q-2010 through 2Q-2011). The LiftOne hydrogen fuel cell-powered lift trucks continued to be shown at sessions conducted with selected end-users at their facilities as well as at the LiftOne branch locations.

Fiscal Year (FY) 2011 Objectives

Through both segments of the project: 1) Education and 2) Deployment, the objective has been focused on increasing hydrogen awareness through:

- Continued education of an ever-broadening group of stakeholders to the benefits of fuel cell and hydrogen technologies in material handling applications to include: facility management, operators, maintenance personnel, safety groups, first responders, authorities having jurisdiction, technical/community colleges.
- Demonstration of fuel cell and hydrogen technology through the continuing demonstration schedule of two hydrogen fuel cell-powered lift trucks in real-world applications at large prominent companies.
- Demonstration of these fuel cell-powered trucks at high profile public events.
- Assisting in the further commercialization of fuel cell and hydrogen technology by establishing a series of cost value propositions to interested companies.

Technical Barriers

This project addresses the following technical barriers from the Education section (3.9.5) of the 2009 Fuel Cell Technologies Program Multi-Year Research, Development and Demonstration Plan:

- (B) Mixed Messages for Education
- Product Performance

FIGURE 1. LiftOne Demonstrating Fuel Cell-Powered Lift Truck at the Odyssey Day Event at Central Piedmont Community College, Charlotte, NC on October 15, 2010

Updated cost justification information has been shared with key company personnel at the sessions.

FY 2011 Accomplishments

- Within the past 12 months, LiftOne successfully completed the project's 6th and final deployment of two CAT[®] electric trucks, each powered by a Hydrogenics Fuel Cell Power Pack. The performance was very good, with all data compiled and sent to the National Renewable Energy Laboratory for analysis and comparison to similar fuel cell projects.
- These LiftOne deployments have allowed important end-users operating large lift truck fleets to test the benefits associated with hydrogen fuel cell power, while experiencing hands-on refueling. Their involvement has enhanced those opportunities present for acquisition and eventual conversion to hydrogen fuel at some point in the future.
- LiftOne's continued participation at strategic regional Clean Energy/Green Expo events again provided a large cross section of the business and local community with an introduction to H₂ power and included live demonstrations of the fuel cell-powered lift truck. These events held in Charlotte (NC), as well as Greenville and Columbia (SC), were attended by well over 1,000 people and increased overall hydrogen awareness levels.
- With the valuable experience gained over the course of the lift truck deployments, LiftOne's Hydrogen Education Program Director Tom Dever has participated as a presenter as well as provided material handling expertise at several notable hydrogen events, and has been referenced in several national fuel cell publications.

Introduction

The materials handling industry, a \$12 billion global market representing approximately 750,000 lift trucks sold each year, has proven to be a significant near-term market for proton exchange membrane (PEM) fuel cell adoption in a mobility application. This is due to the lack of emissions and the increased productivity the technology provides vs. that of using lead-acid batteries or fossil fuels (liquefied petroleum gas, gasoline, diesel) for lift trucks and other material-handling units. As a leading dealership in the Carolinas and Virginia, LiftOne first demonstrated PEM fuel cells in 2007, and was able to gain early field trial experience, while recognizing the acute need for overall hydrogen education.

To assist in facilitating the integration of hydrogen fuel cells into real-world material handling application, LiftOne developed a Hydrogen Education and Awareness Presentation for lift truck users. These sessions have been conducted at each of the LiftOne branches on a rotational basis. Additional sessions have been tailored for

presentations at selected technical colleges, professional organization meetings, industrial shows and to large companies with actual live demos at their facilities. These Hydrogen Awareness Classes began in early 2009, and will continue through August of 2011. The Deployment Segment of the LiftOne project, where the two fuel cell-powered lift trucks are put into real-world applications at six strategically selected major companies' facilities for one-month long trials, have provided an excellent method for demonstrating the viability of fuel cell power. The deployments began in May of 2009 and concluded in August of 2010.

Approach

Recognizing the need to help increase hydrogen awareness among material handling users, LiftOne's approach for Hydrogen Education has been focused on the identification of key target audiences. This strategy has been employed for both the Education and Deployment segments. For the Education segment, the seminar content has been designed for the layman's introduction to hydrogen and included in the 4- to 5-hour long sessions are a thorough review of hydrogen uses, its properties, infrastructure review as well as acquisition cost models and a live demonstration. The target audience for the Education Segment includes representatives from companies operating medium to large electric material handling fleets, with a secondary audience being those operating fossil fuel powered fleets. Smaller fleet operators also have participated.

For the LiftOne Deployment Segment, high profile companies with sizable fleets and multiple locations were selected for the trial sites, in order to gain the best opportunities with potential for effective regional exposure. For each site, presentations and proposals for the trials were made, detailing the equipment, fueler location/regulations, on-site monitoring arrangements and data gathering. At the conclusion of each deployment, comprehensive review meetings are held, in which all performance data presented, feedback from operators reviewed, and a cost justification evaluations presented with full proposals for fuel cell and infrastructure acquisition for more involved "pilot" type projects.

Results

Over the past year, LiftOne has seen positive results in both the Education and Deployment segments associated with the project. Sessions have been conducted at the LiftOne branches, at customer locations, at community colleges and at the regional "Green"-type business expos attended. LiftOne has included the live demonstration of the working fuel cell-powered lift truck, an essential element necessary to satisfy the interest present and maximize awareness.

The Deployment Segment of the project generally yielded very good results. The deployments were conducted at: 1) Stanley Tools, 2) a distribution center (name withheld

by request), 3) Bausch & Lomb, 4) BMW, 5) Electrolux and 6) AGI - In Store, which was conducted this past year (Table 1). There were decent run times, truck performance, power, and ease of refueling (Figure 2). All sites were able to experience fuel cell power, with well over 200 employees at each site made aware of the hydrogen power. As was mentioned at this time last year - LiftOne’s participation at the BMW trial (Site # 4), alongside other fuel cell manufacturers (Plug Power and Nuvera), solidly contributed to that trial’s overall success and BMW’s eventual large-scale fuel cell acquisition in 2010.

TABLE 1. Site # 6 – LiftOne Fuel Cell Deployment Summary

LiftOne Site # 6 - AGI - In Store: 25 days
* Truck 0264 / Cell # 17 ran 190 hrs
* Truck 0265 / Cell # 18 ran 229 hrs
* 86 kg of H ₂ used / 62 fills / 53.75 tanks
* 4.7 minutes average fuel time
* 7.8 hrs avg run time per tank (1.6kg)
Notes: water pump, purge valve
Straight forks - sideshifter application
Good trial - 2 technical issues fixed.
Decent hours run. Good time per tank.

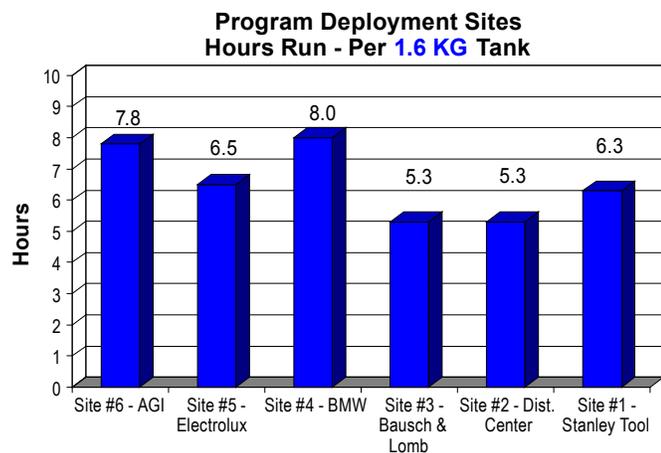

FIGURE 2. LiftOne – Average Hours Run per Tank for all Six Deployment Sites

Conclusions and Future Directions

For the third and final year of the LiftOne Hydrogen Education Program, the following conclusions have been determined:

- A wide variety of users have learned about hydrogen, and seen the fuel cells powering lift trucks in real-world applications. LiftOne’s project addressed this critical “first step”.
- There still remains a large degree of intrigue, but the adoption of fuel cells by major corporations has greatly increased H₂ awareness through the accompanying positive publicity.
- While viable in many large applications, the fuel cell power option is still not economically justified for lift truck fleets of less than 30-35 units at this point in time.
- There is a need for more viable competition in the fuel cell manufacturer arena in order for the necessary price efficiencies, broadened product improvements and size offerings.
- Infrastructure cost remains the major concern for companies considering fuel cell adoption. It has been the single largest obstacle to overcome during proposals.

Future plans for year three of the project involve:

- The LiftOne Hydrogen Education sessions with the live demo will continue at company sites through the remainder of the project term (August 31, 2011).
- LiftOne has considered trying to complete one additional deployment with another supplier’s fuel cells prior to the project’s completion. Time constraints may not allow for this to take place.

E-mail: Greg.Kleen@go.doe.gov

Contract Number: DE-FG36-08GO18106

Project Start Date: October 15, 2008

Project End Date: June 30, 2011

Fiscal Year (FY) 2011 Objectives

California State University, Los Angeles, has partnered with the DOE in addressing the workforce preparation and public education needs of the fuel cell industry and the U.S. economy through a comprehensive set of curriculum development and training activities:

- Developing and offering several courses in fuel cell technologies, hydrogen and alternative fuels production, alternative and renewable energy technologies as means of zero emissions hydrogen economy, and sustainable environment.
- Establishing a zero emissions proton exchange membrane (PEM) fuel cell and hydrogen laboratory supporting curriculum and graduate students' teaching and research experiences.
- Providing engaging capstone projects for multi-disciplinary teams of senior undergraduate students.
- Fostering partnerships with automotive manufacturers and energy providers.

Technical Barriers

This project addresses the following technical barriers from the Education section (3.9.5) of the 2009 Fuel Cell Technologies Program Multi-Year Research, Development and Demonstration Plan:

- (A) Lack of Readily Available, Objective, and Technically Accurate Information
- (B) Mixed Messages
- (D) Lack of Educated Trainers and Training Opportunities

Contribution to Achievement of DOE Education Milestones

This project will contribute to achievement of the following DOE milestones from the Education section of the 2009 Fuel Cell Technologies Program Multi-Year Research, Development and Demonstration Plan:

- Milestone 11: Develop set of introductory materials suitable for a non-technical audience. (4Q, 2006)
- Milestone 21: Launch new university hydrogen education program. (4Q, 2009)
- Milestone 27: Launch high school teacher professional development. (4Q, 2008 through 3Q, 2011)

FY 2011 Accomplishments

- In the 2010-2011 academic year, we continued to offer course modules and hydrogen and fuel cell technology (HFCT) dedicated courses; TECH 470-Electric and Hybrid Vehicles (enrollment 10 technology, eight mechanical); TECH 250-The Impact of Technology on the Individual and Society (detailed in the next section). Milestone 21 (**M:21**).
- TECH 250-The Impact of Technology on the Individual and Society course is a general education required course, which contains one week module on fuel cells and hydrogen economy. It is open to all majors in the university and is selected to deliver our message to the university-wide student body. Multi-section course enrollment exceeded 200 students. **M:21**.
- CSULA students built a fuel cell vehicle and participated in 2011 Shell-Eco competition, Houston, TX. CSULA built fuel cell vehicle Hydrogen Super Eagle was on display at AltCar Expo, Santa Monica 2010, October 2010, Los Angeles Auto Show, in November 2010 and the Metropolitan Water District of Southern California Sustainable Expo, May 2011. The vehicle participated in filming the Mercedes-Benz F-Cell World Drive video EcoTrek 7 (at 3rd minute): <http://www.youtube.com/watch?v=qDPhJsMUBR4>. **M:21**, Milestone 11 (**M:11**).
- CSULA students participated in 2010 and 2011 Hydrogen Design Contests organized by the National Hydrogen Association. **M:21**.
- CSULA has been selected for EcoCAR 2 *Plugging into the Future* competition 2011-2014. **M:21**, **M:11**.
- The College of Engineering, Computer Science and Technology (ECST) is completing the 10 kW solar photovoltaic installation. The system consists of 56 Sharp and 23 Solec modules and three SMA inverters. The funds were provided by Southern California Edison, ECST and this funding. **M:21**.
- There has been an appreciable number of public outreach and educational activities through which fuel cell and hydrogen technologies and the new curriculum

at CSULA were promoted. CSULA participated in numerous meetings and discussions of future projects and collaborations with fuel cell vehicle manufacturers, federal and state government officials. Significant collaboration has been developed with California Fuel Cell Partnership. **M:11.**

- CSULA is completing the construction of a hydrogen station with 60 kg/day generation capacity. That will enable further development of educational program and research into hydrogen technologies. **M:21.**
- Multidisciplinary team of CSULA faculty, including Dr. Blekhman, received National Science Foundation (NSF) funding to establish Center for Energy and Sustainability. The same group has secured American Recovery and Reinvestment Act funding to renovate laboratory spaces including the Zero Emissions Fuel Cell and Hydrogen Laboratory (ZEFC). Dr. Blekhman has been awarded NSF Major Research Instrumentation funding to conduct research into hydrogen purity. These will contribute to the longevity of the research program. **M:21.**

Introduction

Our interest in developing hydrogen and fuel cell education stems from the recognition of the urgent need for workforce development and public education in the entire spectrum of alternative and renewable energy technologies (ARET). ECST is taking steps to graduate more students fluent in ARET as well as to raise campus and state-wide awareness of green technologies. This includes the ongoing construction of a hydrogen fueling station on campus. The comprehensive nature of the university, its strategic location in the hydrogen and fuel cell abundant industrial region and a historically minority-serving charter has made CSULA an ideal candidate to carry out the tasks listed in the objectives.

Approach

Design of a comprehensive engineering and technology curriculum addressing fuel cells and hydrogen technologies is the foundation for our contribution toward green workforce training. This is accomplished through a mix of new courses or special modules in existing courses to introduce the concepts of fuel cell technologies, hydrogen and alternative fuels, alternative and renewable energy technologies as means of zero emissions hydrogen economy, and sustainable environment. ECST has established the ZEFC to support curriculum, undergraduate and graduate students' teaching and research experiences. Further, enrichment of student experiences is accomplished through projects and fostering partnerships with automotive manufacturers and industry.

Community education and public outreach goals are met through a series of on campus and off-campus public events and demonstrations.

Results

The initial grant period was extended by nine months which allowed supporting students that led team efforts in creating a fuel cell vehicle and participating in 2011 Hydrogen Design Contests organized by the National Hydrogen Association. The contest was to design a home hydrogen refueling facility. The twelve-student team included two students from East Los Angeles College. CSULA took 7th place among 17 teams that submitted and 54 registered, third place among the U.S. teams.

An ECST team of six students built a fuel cell vehicle. The team participated in 2011 Shell-Eco competition, Houston, TX. The fuel cell vehicle called Hydrogen Super Eagle was also on display at AltCar Expo, Santa Monica 2010, October 2010, Los Angeles Auto Show, November 2010 and the Metropolitan Water District of Southern California Sustainable Expo, May 2011. The vehicle participated in filming the Mercedes-Benz F-Cell World Drive, see Figure 1. The multi-episode documentary is called Eco Trek and is available on YouTube. CSULA is featured in EcoTrek 7 (at third minute): <http://www.youtube.com/watch?v=qDPHjsMUBR4>.

Two courses with integrated fuel cell/hydrogen modules were offered: TECH 470-Electric and Hybrid Vehicles and TECH 250-The Impact of Technology on the Individual and Society. The latter had multiple sessions throughout the year.

CSULA has actively pursued public outreach and educational activities through which the DOE-sponsored Fuel Cell and Hydrogen curriculum at CSULA was promoted. During the fall of 2010, ECST hosted a Boeing open house for middle and high-school students. More than

FIGURE 1. CSULA-Built Fuel Cell Vehicle Driving along Mercedes-Benz F-Cell World Drive Car

a hundred of them toured the ZEFC. There were multiple additional events with K12 students being introduced to fuel cells, see Figure 2.

CSULA is nearing the completion of a \$4.5 M hydrogen station on campus, see Figure 3. It will deploy the latest technologies with the capacity of 60 kg/day, sufficient to fuel 15+ vehicles or a bus and five more vehicles. The station is utilizing a Hydrogenics electrolyzer, first and second stage compressors capable of fast-filling at 5,000 psi and 10,000 psi, and 60 kg of hydrogen storage. The station will be grid-tied and powered by 100% renewable power.

Dr. Blekhman attended the 2011 Annual Merit Review and 2011 NHA conference both in Washington, D.C., and the 2011 ASEE conference in Vancouver, BC.

Conclusions and Future Directions

CSULA has been very successful in meeting the objectives proposed in the grant. In this extended period of funding, the team has continued to offer courses with modules addressing fuel cell and hydrogen technologies. The work in ZEFC laboratory progressed with the solar installation that will be powering the lab electrolyzer and the rest of the engineering building. Students continued to be challenged through industry and competition projects far beyond those proposed initially.

CSULA is well poised to continue fuel cell and hydrogen educational and research efforts beyond current funding, which provided the foundation for many other activities. Among future activities are operating the hydrogen station, participating in EcoCAR 2 competition and operating a high-quality gas chromatograph-mass spectroscopy for testing hydrogen purity in Southern California. We will also continue our educational program, outreach and collaborations with the industry.

E-mail: Greg.Kleen@go.doe.gov

Contract Number: DE-FG36-08GO18107

Subcontractor:
University of California, Berkeley (UCB), Berkeley, CA

Project Start Date: September 15, 2008
Project End Date: September 15, 2011

Objectives

The Hydrogen Energy in Engineering Education (H₂E³) project is designed to increase awareness of and hands-on experience with hydrogen and fuel cell technology among engineering students in California's public universities. H₂E³'s objectives are:

- To deliver effective, hands-on hydrogen energy and fuel cell learning experiences to a large number of engineering students at multiple campuses in the California State University (CSU) and University of California (UC).
- To provide follow-on internship opportunities for students at fuel cell companies.
- To develop commercializable hydrogen teaching tools including a basic fuel cell test station and a fuel cell/electrolyzer experiment kit suitable for use in university engineering laboratory classes.

Technical Barriers

This project addresses the following technical barriers from the Education section (3.9.5) of the 2009 Fuel Cell Technologies Program Multi-Year Research, Development and Demonstration Plan:

- (D) Lack of Educated Trainers and Training Opportunities.
Only a small number of universities in California offer hydrogen and fuel cell-specific learning opportunities

for undergraduate engineering students. Even at these campuses, the number of engineering faculty with direct experience using fuel cells remains small, and fuel cell course content is underdeveloped.

- (E) Regional Differences. California has the advantages of being home to many hydrogen and fuel cell developers and on the leading edge of hydrogen energy infrastructure development. These features call for a special hydrogen energy education effort in California universities that makes use of these existing resources available in close proximity to many campuses.

Contribution to Achievement of DOE Education Milestones

This project has contributed to achievement of the following DOE milestone from the Education section of the Fuel Cell Technologies Program Multi-Year Research, Development and Demonstration Plan:

- **Milestone 21:** Launch new university hydrogen education program (4Q, 2009).

The project supports attainment of the above milestone by creating curriculum, teaching tools, and industry-based learning opportunities that can be replicated by other universities working with industry partners. By the same token, the project also supports completion of Task 5 in the Multi-Year Research, Development and Demonstration Plan: "Facilitate Development and Expansion of College and University Hydrogen Technology Education Offerings," specifically the subtask described as "Work with university partners to develop and expand hydrogen technology course offerings and facilitate networking among schools with similar programs."

Fiscal Year (FY) 2011 Accomplishments

- Continued expansion of H₂E³ curriculum adoption at host universities HSU and UCB, including activities for three additional courses:
 - Transport phenomena (ENGR 416) at HSU, in which students used a fuel cell test station to perform a heat balance on an operating fuel cell stack.
 - Renewable energy power systems (ENGR 475) at HSU, in which students evaluated fuel cell stack performance under different temperature and air stoichiometry conditions.
 - A hydrogen safety seminar at UCB, in which graduate engineering students visited UCB's new hydrogen fueling station and attended a safety presentation alongside local emergency responders.

- Visited and/or supplied sample experiment kits to faculty at seven California universities:
 - California State University, Los Angeles
 - San Francisco State University
 - Sonoma State University
 - University of California, Santa Cruz
 - Berkeley Center for Green Chemistry
 - University of California, Riverside
 - California State University, San Bernardino
- Successfully recruited faculty from three universities to adopt curriculum:
 - San Francisco State University
 - Sonoma State University
 - University of California, Riverside
- Fabricated 24 additional hydrogen experiment kits for placement at newly recruited campuses.
- Developed the project website (hydrogencurriculum.org) to include curriculum downloads, equipment user manuals, streaming videos, project news, and recommended readings.
- Planned, filmed, edited, and posted online (hydrogencurriculum.org) nine instructional videos explaining how to use the H₂E³ laboratory equipment.
- Facilitated creation of two fuel cell development intern positions at Protonex Technology Corporation for summer 2011; filled these positions with two HSU engineering students who had previously participated in H₂E³ curriculum.
- Performed monitoring and evaluation of classroom and lab activities.

Introduction

A recurring theme in the hydrogen energy field is the unmet need for a new generation of graduating engineers trained specifically in hydrogen and fuel cell energy technologies. The purpose of our project is to help meet this need, specifically in the context of the California State University and University of California systems. Together these universities grant over 7,000 engineering degrees each year.

The three-year project, branded as “Hydrogen Energy in Engineering Education” (H₂E³) is being led by the Schatz Energy Research Center, a unit of the Humboldt State University Sponsored Programs Foundation. Our principal partner on the project is the UCB, represented by their Institute of Transportation Studies. The project also includes fuel cell industry partner Protonex Technology Corporation, which is providing internships for students who have participated in the curriculum.

Approach

Adding hydrogen curriculum to existing undergraduate engineering programs is not a trivial task. Engineering departments and the organization that accredits them require students to meet numerous stringent requirements in order to graduate. There is little slack in a typical undergraduate engineering course plan to add new curriculum. In order to add hydrogen education to existing engineering programs, we need to find creative ways to fold it into courses and help instructors meet their existing course objectives.

We have worked closely with engineering faculty as part of this project to develop lesson plans that can be substituted for segments of existing courses, including introductory engineering, introductory and advanced thermodynamics, renewable energy power systems, transport phenomena, and in courses on the general topic of energy and society. We have also developed laboratory hardware that students use to perform hands-on experiments that reinforce key points covered in the lecture material. The partners on this effort bring years of relevant experience in teaching about hydrogen energy and developing fuel cell technology.

Results

During the first two years of the project, the focus was primarily on development of curriculum and the related lab equipment. In the third year, we are focused on marketing and distributing the curriculum to other universities and creating follow-on internships for participating students.

Curriculum Development and Deployment. At HSU and UCB, we continued use of the curriculum in courses where it was introduced in year two. We also brought the curriculum into several new courses at these and other campuses. Table 1 details progress to date in incorporating curriculum in various courses.

While the project was originally designed to reach undergraduate engineering students, we have found the curriculum has broader appeal. For example, the curriculum is being used at Sonoma State University with students in a non-engineering energy management and design program. The curriculum is also being evaluated for use in training high school science teachers at California State University, San Bernardino. Reviewers at the 2011 Annual Merit Review meeting also suggested that the curriculum should be adapted for use with high school students.

Equipment Deployment. Using \$15,000 in supplemental funding from DOE, we produced an additional 30 hydrogen experiment kits for distribution to newly participating campuses. We have placed most of these kits at the campuses that have joined the project during year three. Most of the kits are being used to perform lab activities developed by Schatz Energy Research Center. However, one UCB chemistry professor assigned her students to work in teams to analyze performance of the

UC Riverside				<ul style="list-style-type: none"> • Green Engineering

kits and recommend improvements. The students presented their work in a May 2011 poster session (see Figure 1).

Curriculum Marketing. Our project Web page (hydrogencurriculum.org) is aimed principally at faculty and features downloadable presentations, streaming videos produced in-house on using the equipment (see Figure 2), handouts for lab activities for a variety of courses, and a recommended readings list. Project staff visited faculty at four campuses (see Figure 3), bringing them sample kits and curriculum. Additional kits were shipped to interested faculty at other campuses.

Monitoring and Evaluation. We continued to use pre- and post-activity assessments of student learning at HSU in all courses where the curriculum was used. In addition, faculty at University of California, Riverside and Sonoma State University agreed to provide pre- and post-activity assessments and written feedback on use of the lectures and labs in their courses. This process has been helpful

FIGURE 2. Still from one of the H₂E³ lab equipment instructional videos produced and posted online.

FIGURE 1. UC Berkeley chemistry student Nisha Mair displays her team's poster explaining their efforts to measure and improve performance of the H₂E³ hydrogen experiment kits.

FIGURE 3. San Francisco State University engineering faculty evaluate H₂E³ hydrogen experiment kit.

in making iterative improvements to the curriculum and equipment (see Figure 4).

Fuel Cell Industry Internships. Due to the economic downturn, we experienced difficulty during years two and three in placing interns with fuel cell companies as had been originally envisioned. In the second quarter of 2011, we determined that we could reallocate a portion of our project budget to cost share with companies on intern stipends. Using this funding mechanism, we successfully placed two HSU students at Protonex Technology Corporation, where they are currently working on proton exchange membrane and solid oxide fuel cell projects.

Conclusions and Future Directions

As this three-year project nears its September 2011 conclusion, it has been a success on many fronts, reaching well over a thousand students at five campuses. Student and instructor responses to the curriculum and equipment have been very positive. The strategy of using fuel cells and hydrogen energy concepts to meet the teaching objectives of existing engineering courses has been well-received by faculty.

In order to bring the funded project to completion we will:

- Continue to facilitate and evaluate the ongoing student internships.
- Produce two additional instructional videos, a virtual tour of the hydrogen fueling station at HSU and assembly of a PEM fuel cell stack.
- Continue to refine and extend the Web page.
- Determine who will be given continuing stewardship of the lab equipment.

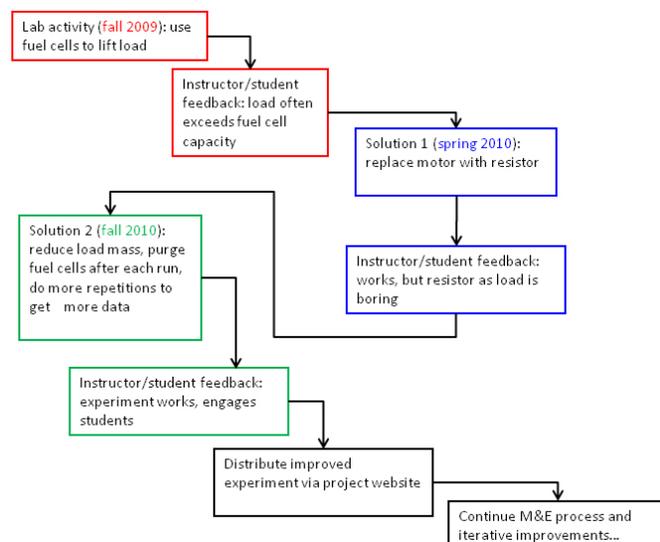

FIGURE 4. Example of iterative improvements to curriculum using monitoring and evaluation process.

Beyond the current funding, we hope to:

- Maintain and build on our established collaborations with other campuses in California.
- Identify universities outside California interested in adopting the curriculum.
- Seek manufacturing partners to commercialize the kits and/or test stations, scaling them up for mass production.
- Seek an opportunity to adapt the curriculum for high school use, as recommended by reviewers at the 2011 Annual Merit Review meeting.

FY 2011 Publications/Presentations

1. Materials for Probability and Statistics Course
 - Pre-lab lecture presentation: “The HSU Hydrogen Fueling Station”
 - Assignment handout: “Performance of the Electrolyzer at the HSU Hydrogen Fueling Station”

Contribution to Achievement of DOE Education Milestones

This project will contribute to achievement of the following DOE milestones from the Education section (3.9) of the Fuel Cell Technologies Program Multi-Year Research, Development and Demonstration Plan:

- **Milestone 21:** Launch new university hydrogen education program. (4Q, 2009)

FY 2011 Accomplishments

The major accomplishments of this project to date are listed as follows:

- We have developed and taught one lecture and one laboratory course in hydrogen energy and two courses in fuel cells.
- Over 40 modules have been developed to introduce students in core chemical engineering courses to hydrogen and fuel cell technology; similar efforts have been accomplished for core mechanical engineering (20 modules) and electrical engineering (6 modules) courses.
- 90 example problems have been created as supplementary material to be used in the sophomore level introductory chemical engineering course.
- Over 70 example problems have been created as supplementary material to be used in the junior level courses in fluid mechanics, heat transfer, and mass transfer fundamentals and their associated unit operations.
- Over the entire project, fifteen oral presentations have been given and seven conference proceedings have been published, with six oral presentations and two conference proceedings during the past year.

Fiscal Year (FY) 2011 Objectives

The objectives of this project are to educate university students on the advantages, disadvantages, challenges, and opportunities of hydrogen and hydrogen fuel cells within the United States energy economy. In particular, this project will:

- Develop and/or refine courses in hydrogen technology.
- Develop curriculum programs in hydrogen technology.
- Develop modules for core and elective engineering courses.
- Develop modules to supplement commonly used chemical engineering texts.
- Meet all Department of Energy project management and reporting requirements.

Technical Barriers

This project addresses the following technical barriers from Education section (3.9) of the Fuel Cell Technologies Program Multi-Year Research, Development and Demonstration Plan:

- (A) Lack of Readily Available, Objective, and Technically Accurate Information
- (B) Mixed Messages
- (C) Disconnect between Information and Dissemination Networks

Introduction

There is a strong need for a transformative curriculum to train the next generation of engineers who will help design, construct, and operate fuel cell vehicles and the associated hydrogen fueling infrastructure. In this project, we build upon the project-based, hands-on learning that has been a cornerstone of engineering education at Michigan Technological University (MTU). This teaching and learning style is supported by the engineering education literature which indicates that students learn by doing, particularly through team-based interactive projects with a real-world flavor.

This project has resulted in the formation of an “Interdisciplinary Minor in Hydrogen Technology” at MTU. We focus on student centered design projects, and add additional technical material through elective courses, modules for core courses, and textbook supplements. As a final note, aggressive dissemination of the project results will occur through presentations at the annual meetings of several professional societies.

Approach

The ultimate goal for the hydrogen education program should be to establish an educational infrastructure and database of hydrogen and fuel cell related educational materials, particularly projects and problem sets. The efforts of this project support this mission.

At MTU, we have embraced the concept of hands-on learning as the cornerstone of a newly approved “Interdisciplinary Minor in Hydrogen Technology.” Students that obtain this minor are also required to take newly developed elective courses in fuel cells and hydrogen technology. Focusing on a subset of graduates who choose these options is not enough. In order to reach a wider audience at MTU, modules are being developed for the core curricula in chemical engineering, mechanical engineering, and electrical engineering. Each module stands alone and can be assigned to students as an in-class problem, a homework assignment, or a project. The modules use the fundamental concepts taught within the core course and apply them to hydrogen generation, distribution, storage, or use within a fuel cell. Thus, students are able to see the applications of the fundamentals from their courses. Finally, we are creating supplements to two of the most popular chemical engineering textbooks as another way to introduce hydrogen technology and fuel cells to university students.

The core course modules are to be tested throughout the nation. The results of this curriculum project and testing results are to be disseminated through professional societies in chemical engineering, mechanical engineering, electrical engineering, and engineering education. Course materials, modules, and textbook supplements will be available for use by engineering educators worldwide.

Results

Results for Task 1.0, Develop and/or Refine Courses in Hydrogen Technology:

- To date, we have created two new courses, “Fundamentals of Hydrogen as an Energy Carrier” to be taught in fall semesters and “Hydrogen Measurements Laboratory” to be taught in spring semesters. We also modified two fuel cell courses. The hydrogen as an energy carrier course and both fuel cell courses were taught during the most recent academic year and were well received by students.

Results for Task 2.0, Develop Curriculum Programs in Hydrogen Technology:

- The “Interdisciplinary Minor in Hydrogen Technology” was approved by the university effective April 2009.
- The “Graduate Certificate in Hybrid and Electric Vehicles” was approved by the university effective May 2010.
- During the 2010-2011 academic year, there were several group projects in the “Alternative Fuels Group” Enterprise. This enterprise consisted of undergraduate students in chemical, mechanical, and electrical engineering, as well as materials science and engineering. Students were in their sophomore, junior, or senior year of study. By participating in the group projects, students earned credit towards their degree and (if desired) towards the new minor mentioned above. Student projects included:
 - Design of methanol production facility for use in direct methanol fuel cell (DMFC) applications (Figures 1 and 2) and analysis of DMFC membrane materials.
 - Integration of Bloom Box solid oxide fuel cells (SOFCs) into the Michigan Technological University electrical grid.

Results for Task 3.0, Develop Modules for Core and Elective Engineering Courses:

- The third task of this project is to develop modules for core courses in chemical, mechanical, and electrical engineering courses. Up to this point, we have developed over 40 chemical engineering modules, 20 mechanical engineering modules, and six electrical engineering modules. It is noted that the modules are available online at: http://www.chem.mtu.edu/~jmkeith/fuel_cell_curriculum/. Plans have been made to test these modules in the classroom at the following institutions: MTU, University of Michigan, Bucknell University, Illinois Institute of Technology, Michigan State University, Mississippi State University, Tennessee Technological University, University of Kentucky, Rowan University, San Jose State University, Oklahoma State University, University of Wyoming, and the University of Texas at Austin. Student feedback at these other institutions has been very positive.

Results for Task 4.0, Develop Modules to Supplement Commonly Used Chemical Engineering Texts:

- We have developed a set of 90 examples to supplement the textbook *Elementary Principles of Chemical Processes* authored by R. M. Felder and R. W. Rousseau and published by Wiley. The problems are organized in “workbook” format where there are blank spaces for students to insert numbers in order to carry out the solutions. It is noted that this textbook is used in the very first chemical engineering undergraduate course

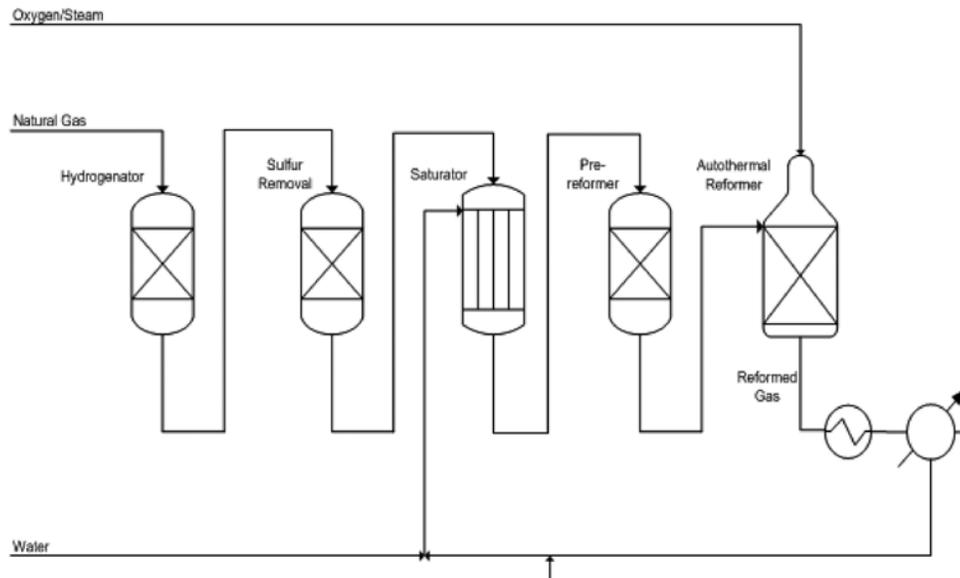

FIGURE 1. Process Diagram for Hydrogen Production via Steam Reforming

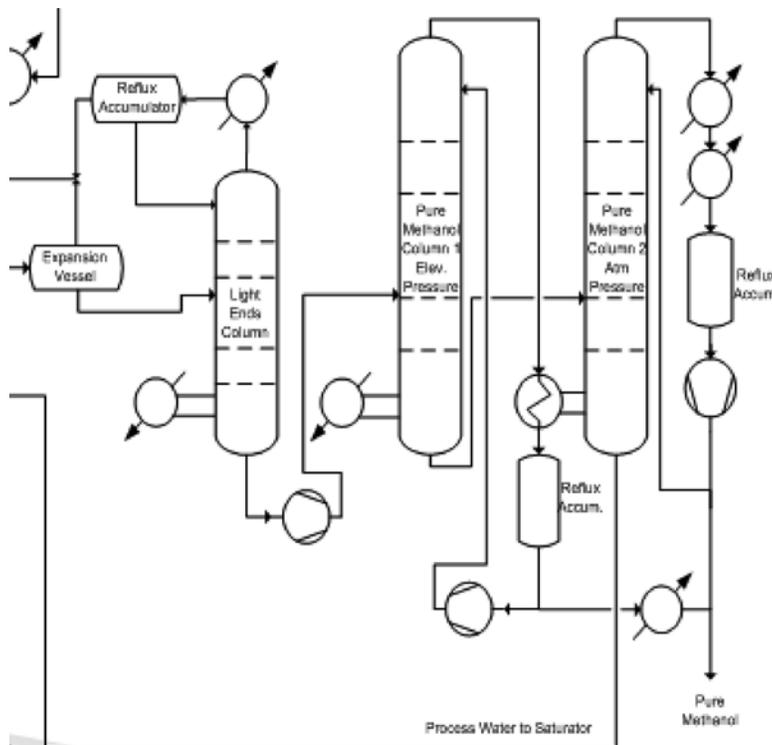

FIGURE 2. Process Diagram for Methanol Purification

at most universities in the nation. The main emphasis of the course is on engineering problem solving for chemical engineers. Students learn best by solving a large number of problems. This supplement is intended to meet the student's needs while teaching them about hydrogen technology and fuel cells.

- We have developed a set of over 70 examples to supplement the textbook *Transport Processes and Separation Process Principles* authored by C.J. Geankoplis and published by Prentice Hall. These problems follow the same format as those described above, and can be used to integrate fuel cell and hydrogen production concepts into fluid mechanics, heat transfer, and mass transfer topics and their associated unit operations.

Results for Task 5.0, Project Management and Reporting:

- To date, 10 quarterly reports (out of 12) have been submitted. In addition, a Powerpoint presentation was prepared and an oral presentation was given at the Annual Merit Review.

Conclusions and Future Directions

The most significant result of this project to date is the approval of a new minor at MTU with title "Interdisciplinary Minor in Hydrogen Technology." The groundwork is in place to teach new courses in hydrogen and fuel cell technology and to introduce these concepts in the core chemical engineering curriculum at MTU.

This project is nearing a close. The remaining modules (Task 3) and reports (Task 5) will be completed by the end of the project.

Subcontractor:

University of North Carolina at Charlotte, NC

Project Start Date: August 1, 2008

Project End Date: September 30, 2011

Contribution to Achievement of DOE Education Milestones

This project will contribute to achievement of the following DOE milestones from the 2009 Fuel Cell Technologies Program Multi-Year Research, Development and Demonstration Plan:

- Milestone 21 – Facilitate development and expansion of college and university hydrogen technology education offerings.

FY 2011 Accomplishments

The HFCT project was successful and accomplished all its goals and objectives as follows:

- All hydrogen and fuel cell courses have been developed and offered at UNCC.
- All laboratories were equipped and experiments were developed and offered.
- A HFCT program concentration was implemented as an option in the UNCC engineering programs.
- Industry collaborations are established.
- The program continues as part of national HFCT educational work, is positioned for continuation, and future activities are planned.

The website for HFCT is part of the UNCC engineering programs as follows:

<http://et.uncc.edu/about-us/facilities-a-labs/178.html>.

The UNCC website is <http://www.uncc.edu/>.

Introduction and Approach

The objective of the Hydrogen and Fuel Cell Technology education program is to develop and deliver an accredited baccalaureate level HFCT educational program at the UNCC. This objective has been successfully accomplished by developing HFCT courses and associated laboratories, teaching the new courses and labs and integrating the HFCT option into the UNCC mechanical engineering technology and mechanical engineering programs. The program has also established ongoing collaborations with the UNCC energy related centers. The HFCT courses have been offered successfully and student enrollments are good. HFCT results have been disseminated and published and the program has cooperative efforts with industries representatives. The HFCT program has addressed DOE goals by supplying readily available, objective and technically accurate information that is available to students, industry and the public. In addition, the program has supplied

Fiscal Year (FY) 2011 Objectives

- Develop and implement an accredited engineering technology baccalaureate program in hydrogen and fuel cell technologies (HFCT) at the University of North Carolina at Charlotte (UNCC).
- Prepare students to work as hydrogen and fuel cell technology professionals in government, industry, and academia.
- Prepare program graduates with a mastery of the knowledge, techniques, skills and modern tools related to hydrogen and fuel cell technologies.
- Prepare program graduates with the ability to apply current knowledge and to adapt to emerging applications in the area of hydrogen and fuel cell technologies.
- Disseminate program information and HFCT activities to community colleges, high schools, industrial partners, governmental agencies, other universities, and the public.

Technical Barriers

This project addresses the following technical barriers from the Education section (3.9.5) of the 2009 Fuel Cell Technologies Program Multi-Year Research, Development and Demonstration Plan:

- (A) Lack of readily available, objective, and technically accurate information
- (F) Mixed messages

educated trainers and training opportunities for the next generation workforce needed for research, development, and demonstration activities in government, industry, and academia.

The UNCC is an urban university that has a student body of 24,700 and offers 92 bachelors, 59 masters, and 18 doctoral programs. The HFCT courses are part of the UNCC College of Engineering. The engineering college has 4,000 students with 950 students in the Mechanical Engineering Department and 850 students in the Engineering Technology Department.

Results

The HFCT project was comprised of the completion of five project tasks and the results of the project activities can be presented as two major areas – course and laboratory development and offerings and program recruitment, promotions and collaborations.

I. Course and Laboratory Development and Offerings

Over the project period, the primary activity has been the development and offering of the HFCT courses and accompanying laboratories. This process has taken three years with the courses first being developed and then offered each year over the timeframe. The 11 courses that were developed and offered are presented in Table 1.

These courses are described as follows.

1. **Applied Energy Systems – ETM 4220.** The Applied Energy Systems course is an introduction course to topics of energy, work and thermal systems and processes. The course presents fundamentals of

thermodynamics, electricity and nuclear technologies and the process of obtaining electricity from solar, wind, biomass and geothermal energy sources. The course also includes the efficiency of the different energy sources and effects on the environment. A one semester-long group project is assigned to students.

2. **Analysis of Renewable Energy – ETGR 3000-01 & ETME 4250.** The Renewable Energy course is an upper level course that looks at analysis of renewable energy systems. Topics include well-to-wheels analysis, lifecycle energy and emissions and total cost. Students learn skill sets, methodologies and tools needed to analyze various technologies on a consistent basis for a given application.
3. **Combined Hydrogen Production & Storage with Labs – ETGR 3000-02, MEGR 3090-020 & ETME 4260.** The Combined Hydrogen Production & Storage with Labs course presents basic concepts and principles of hydrogen technologies to include properties, usage, safety and a fundamental understanding of hydrogen storage and production technologies. The three laboratories are:
 4. **Laboratory 1: Hydrogen and Fuel Cell Experiment.** Purpose: To calculate well-to-wheel values.
 5. **Laboratory 2: Hydrogen as an Energy Carrier.** Purpose: To calculate power output from photovoltaics input to electrolyzer and the power outputs from fuel cell. Find photovoltaics max current and max power point locations on a voltage-current (V-I) curve.
 6. **Laboratory 3: Methanol Fuel Cell.** Purpose: To draw V-I curve, interpret characteristic curve, enter operating voltage and current of the motor in V-I characteristic curve, draw power-current diagram, and calculate motor's power consumption and enter the values in power vs. current diagram.

TABLE 1. HFCT Courses and Course Offerings

Course	Prefix	Credit Hours	Offered	Future Offering
Applied Energy Systems	ETM 4220	4	Spring 2009	
Analysis of Renewable Energy Systems	ETGR 3000-01 and ETME 4250	3	Spring 2010	Spring 2011
Combined Hydrogen Production & Storage with Labs	ETGR 3000-02, MEGR 3090-020 and ETME 4260	3	Summer 2010	Summer 2012
Lab 1: Hydrogen and Fuel Cell Experiment	Part of ETGR 3000	-	Summer 2010	Summer 2012
Lab 2: Hydrogen as a Energy Carrier	Part of ETGR 3000	-	Summer 2010	Summer 2012
Lab 3: Methanol Fuel Cell	Part of ETGR 3000	-	Summer 2010	Summer 2012
Fuel Cell Tech 1	ETGR 3000-M01 MEGR 3090-M03 and ETME 4270	3	Fall 2010	Fall 2011
Lab 1: Assembly MEA FC	Part of ETGR 3000	-	Fall 2010	Fall 2011
Lab 2: Fuel Cell Performance Testing	Part of ETGR 3000	-	Fall 2010	Fall 2011
Lab 3: FC Performance as function of temp. & humidity	Part of ETGR 3000	-	Fall 2010	Fall 2011
Senior Design Course	MEGR 3255-001 ETGR 4100-EC1	4	Spring 2010, Fall 2010, Spring 2011.	Fall 2011

7. **Fuel Cell Tech I with Labs– ETGR 3000-M01 & MEGR 3090-M03 & ETME 4270.** The Fuel Cell Tech I with Labs course presents basic concepts and principles of fuel cell technologies to include chemistry, thermodynamics, electrochemistry, cell components, operating conditions and fuel cell systems. The three laboratories are:
8. **Laboratory 1: Assembling a 3-layer Membrane Electrode Assembly (MEA) Fuel Cell.** Purpose: To learn and practice the assembly of a proton exchange membrane (PEM) fuel cell.
9. **Laboratory 2: Fuel Cell Performance Testing.** Purpose: To acquire understanding and experience in employing electrochemical test methods to determine the performance characteristics of a hydrogen PEM fuel cell, to become acquainted with the concepts of fuel cell reactant consumption rates and utilization and the associated calculations and to evaluate the performance of PEM fuel cell as a function of O₂ concentration and stoichiometry with an emphasis on their effects on electrode kinematics, mass transport limitations and cell resistance.
10. **Laboratory 3: Performance of a hydrogen PEM fuel cell as a function of temperature and humidity.** Purpose: To implement basic experimental and analysis techniques that demonstrates and characterizes the performance of a hydrogen PEM fuel cell as a function of temperature and reactant gas humidity levels.
11. **Senior Design Course – MEGR 3255-001 & ETGR 4100-EC1.** The Senior Design course is a two semester for four hours “capstone” or final year experience intended to integrate a students’ academic training with real-world engineering projects and community partners.

II. Promoting the Program through Advertisement, Recruiting Students and Outreach Plans

The objectives of this task are to recruit students, to promote the HFCT program and to disseminate information on the program and its activities in order to form collaborations with industrial partners, governmental agencies and other universities. Details follow.

Recruit Students: In an effort to recruit as many students as possible, the team has hosted seminars and visited community colleges and high schools. These efforts have concentrated on community colleges that currently have technology programs with potential to transfer students directly into the HFCT option of the Bachelor of Science in Engineering Technology program.

Program Promotion and Collaborations: Closely tied with recruiting students is the promotion of the HFCT program with various organizations and groups in order to receive external recognition and support. Industry collaborations are also closely tied with these promotion efforts. Industry, national laboratories and technical organizations were visited under this sub task.

Conclusions and Future Directions

The HFCT education project has successfully developed courses and associated laboratories, taught the new courses and labs and integrated the HFCT option into the accredited mechanical engineering technology and mechanical engineering programs at the UNCC. The HFCT courses have been offered successfully and student enrollments are good.

Future plans include the continued offering and evaluation of the developed courses and labs at UNCC, continued project promotion and collaborations with industry, university and other organizations, the development of web-based HFCT courses, the extension to a Master of Science program and the development of a research component.

Contract Number: DE-FG36-08GO18110

Project Start Date: August 30, 2008
Project End Date: September 1, 2011

Fiscal Year (FY) 2011 Objectives

The objective of this project is to develop a comprehensive university level education program that will:

- Provide exposure to the basics of hydrogen-based technologies to a large number of students. This exposure will provide a level of training that will allow students to converse and work with other scientists and engineers in this field. It will also serve to spark a level of interest in a subset of students who will then continue with more advanced coursework and/or research.
- Provide a “mid-level” training to a moderate level of students. More detailed and directed education will provide students with the ability to work to support industry and government development of hydrogen technologies. This level of training would be sufficient to work in the industry, but not be a leader in research and development.
- Provide detailed training to a smaller subset of students with a strong interest and propensity to make significant contributions to the technology development. These individuals will have extensive hands-on experience through internships that will allow them to play a major role in industry, government, and academia.

For the purposes of this grant, the terms hydrogen-based technologies, hydrogen energy and hydrogen education are used broadly to include the production, transport, storage, and utilization of hydrogen. This includes both electrolysis and fuel cell applications.

Technical Barriers

This project addresses the following technical barriers from the Education Section (3.9) of the 2009 Fuel Cell Technologies Program Multi-Year Research, Development and Demonstration Plan:

- (A) Lack of Readily Available, Objective, and Technically Accurate Information
- (B) Mixed Messages
- (C) Disconnect Between Hydrogen Information and Dissemination Networks
- (D) Lack of Educated Trainers and Training Opportunities

Contribution to Achievement of DOE Education Milestones

This project will contribute to achievement of the following DOE milestones from the Education Section of the 2009 Fuel Cell Technologies Program Multi-Year Research, Development and Demonstration Plan:

- **Milestone 21:** Launch new university hydrogen education program. (4Q, 2009)

FY 2011 Accomplishments

There were seven tasks in this project. Major accomplishments include:

- Task 1 – Case Study Development: Case studies were developed and implemented into the undergraduate curriculum. The most successful of these case studies were presented for publication in the National Science Foundation (NSF) National Center for Case Study Teaching in Science.
- Task 2 – Development of New Courses: A new course, Hydrogen Production and Storage was developed. The content of our Renewable Energy Systems course was modified to highlight fuel cells and electrolysis and Fuels Technology was modified to highlight hydrogen production technologies. All courses were taught simultaneously to undergraduate, graduate and distance students
- Task 3 – Laboratory Experiments in Hydrogen: Experiments were developed for undergraduate chemical and electrical engineering laboratory classes. The experiments are accomplished using three sets of equipment – a single-cell electrolyzer/fuel cell combination, a 40-watt fuel cell system, and a 600 watt fuel cell system. A set of experiments was designed to demonstrate fuel cell membrane design, construction and testing.

- Task 4 – MS/PhD Teaching Experience: Doctoral (PhD) and Masters of Science (MS) students developed laboratory experiments, provided input for case studies, and participated in summer outreach programs for undergraduate students.
- Task 5 – Summer Internship: The project helped place summer interns at the National Renewable Energy Laboratory (NREL), Oak Ridge National Laboratory, and the DOE National Center for Hydrogen Technology.
- Task 6 – Hydrogen Seminary Series: Students were exposed to various aspects of hydrogen technology through a series of seminars that were offered each semester. Students were provided with the opportunity to attend the annual UND Energy & Environmental Research Center Hydrogen Summit.
- Task 7 – Develop Modules for PowerOn!: PowerOn provides hands on demonstrations for students in grades 4-9. A special topics class engaged students in the development and presentation of these modules.

Introduction

The basic concept of the project is to introduce hydrogen education to a broad distribution of students through the use of structured case studies and experiments that are built into the students required coursework. This guarantees that all undergraduate students in the program will be exposed to the technologies. This level of exposure should generate interest in a subset of these students who would then be interested in taking full semester courses related to hydrogen technologies. This will provide a significant cohort of students that will have a good understanding of the basics making them candidates for entry level jobs in hydrogen-related industries. A smaller subset of these students showing strong interest and aptitude will participate in directed research and internships to produce bachelor of science, MS, and PhD graduates that will play a major role in the future development of the hydrogen technology. UND's distance education experience will be used to reach a large and widely dispersed group of students.

Approach

UND is taking advantage of existing infrastructure and programs to provide a comprehensive renewable hydrogen production and fuel cell education program. This program is comprehensive from the standpoint of the level and number of students that will be involved in the program. It is designed to provide multi-discipline formal training to both undergraduate and graduate level engineers and scientists. This will be accomplished by developing case studies that will be implemented into classes through all four years of the undergraduate curriculum. These case studies will be broadly disseminated through the National Center for Case

Studies in Science Teaching website making them available to any school in the United States. Two new classes will be generated that will be offered as technical electives at the undergraduate and graduate level. In addition to our on-campus students, the undergraduate class will also be offered through our Distance Education Degree Program (DEDP) to provide access to hundreds of off-campus students across the country and other nations. UND's DEDP program is the nation's only ABET EAC accredited undergraduate engineering program. Several new hydrogen-related student experiments will be added to our undergraduate laboratory sequence to provide hands-on experience for our students. Additional hands-on experience will be available to selected students through summer intern programs to be established with NREL and Proton Energy Systems (designer and manufacturer of proton exchange membrane [PEM] hydrogen production systems). UND will develop a hydrogen seminar, bringing in experts in the field from NREL and Proton to present to UND students. Internships and research opportunities are also available for students at UND Energy & Environmental Research Center.

This program is designed to provide an introduction of hydrogen energy to a large number of students, both on and off the UND campus through the case studies and student laboratories. It will provide more detailed training on the topic to a smaller, but still significant group of students through new courses added to our curriculum and offered through our distance program. In-depth training will be provided to a select group of undergraduate and graduate students through in-house research and internships. We feel this approach will provide high quality students with the exposure of hydrogen energy required to support research, development, and demonstration activities in the government, industry and academia sectors.

Results

A variety of case studies were developed for the undergraduate curriculum, designed to fit into specific courses with the intent of reinforcing fundamental concepts using hydrogen production and/or utilization examples. While these were found to provide a good introduction to hydrogen, there was some difficulty incorporating these into core courses. While most faculty like new problems for application in their courses, they have limited time within the semester schedule to add significant content. They found it difficult to implement a case study that required a whole class period. A better approach was found to be utilizing the problem-based learning concept implemented in the Michigan Tech program, where shorter directed-problems were developed.

Case studies were found to be successful in survey courses where faculty are looking to expose students to examples of how technology can meet the needs of today's society. These courses are good places to introduce "non-technical" aspects of engineering to students, such as political and social constraints in making engineering

decisions. The most successful case studies were presented for publication in NSF National Center for Case Study Teaching in Science.

A new course, Hydrogen Production and Storage was developed and added to the curriculum. In addition, the content of our Renewable Energy Systems course was modified to highlight fuel cells and electrolysis and our Fuels Technology course was modified to highlight gasification and other hydrogen production technologies. These courses were effective in stimulating interest in hydrogen related technologies. An indication of this interest is the number of students choosing hydrogen related projects for their senior design. All courses were taught simultaneously to undergraduate, graduate and distance students to help maximize exposure.

An existing Hydro-Geniuses laboratory experimental setup consisting of a solar cell, a single-cell PEM electrolyzer, two single-cell PEM fuel cells, and a small resistive load is used by students to generate the current-voltage characteristic curves of the fuel cell and the electrolyzer and analyzed system efficiencies. The two fuel cells were operated both in series and in parallel. Two new series of laboratory experiments have been developed and implemented into the undergraduate curriculum using new experimental setups purchased from Heliocentris through the support of the DOE Hydrogen Education Program. The HP 600 includes a 600 watt water-cooled PEM fuel cell stack, a direct current (DC)/DC and DC/alternating current (AC) converter, metal hydride storage kit, electric load, and an integrated control system. The off-grid instructor includes a 40-watt fuel cell with integrated microprocessor, electronic load, metal hydride storage, and the constructor kit. A Masters student developed the set of laboratories that were implemented into the undergraduate curriculum.

To help improve the depth of knowledge and skills of our MS and PhD candidates, a variety of teaching experience opportunities were provided. PhD and MS students developed the laboratory experiments for implementation in the undergraduate labs. This provided the opportunity to test the equipment and determine which of its capabilities could be best utilized to demonstrate the fundamentals of hydrogen based energy. These students also provided input for case studies and participated in the summer outreach programs for undergraduate students.

One of the goals of this program was to provide internship opportunities for students that received training through a combination of their laboratory experience and the hydrogen related classes. This training was expected to add value to the student, making it easier for them to obtain internships. Students were placed in summer internships at NREL, Oak Ridge National Laboratory, and the DOE National Center for Hydrogen Technology.

Students were exposed to various aspects of hydrogen technology through a series of seminars that were offered each semester. Students were also provided with

the opportunity to attend the annual UND Energy & Environmental Research Center Hydrogen Summit.

PowerOn is an outreach activity that provides hands on demonstrations for students primarily in the grades 4-9. The demonstrations and the infrastructure to support PowerOn are provided from other non-project funds. A special topics class engaged students in the development and presentation of these modules. Having students develop these modules on a “for credit basis” rather than for pay allowed projects to be developed without any monetary contributions from the project. Presentation of the PowerOn demonstrations allows students to gain practice in presenting engineering related concepts to the general public. While the general audience in middle school, experience has been that kids of all ages have a strong interest. The program also indirectly educates parents, as they often accompany their children in these public events.

Conclusions and Future Directions

Over 200 students were directly impacted by program.

- Over 150 chemical and electrical engineering undergraduate students were exposed to various aspects of hydrogen through in-class case studies and laboratory experiments.
- Twenty-seven students were involved in senior design projects related to hydrogen.
- Three hydrogen related courses were developed and taught, with enrollment of 73 students.
- Twenty-one undergraduate students were involved with PowerOn to develop modules to demonstrate hydrogen and other renewable energy technologies. Demonstrations were made to over 1,000 youth.
- Two PhD and two MS students were trained through the development of instructional material for this program. Nine interns were placed working in hydrogen related fields.
- Two undergraduates were placed at the DOE National Hydrogen Center and one at NREL. Two PhD graduates were placed with Nissan in their fuel cell division in Detroit.
- Results of this work have been presented at the 2010 annual American Society for Engineering Education meeting in addition to the DOE annual merit review meetings.

The final activities of this project will be to publish selected case studies and to publish a paper that summarizes the lessons learned during this program.

Special Recognitions

The paper, “National Hydrogen and Fuel Cell Education Program Part I: Curriculum” received the Best Paper Award at the ASEE Annual Conference and Exposition.

E-mail: Reginald.Tyler@go.doe.gov

Contract Number: DE-FG36-04GO14278

Subcontractors:

- Sentech, Inc., Bethesda, MD
- Los Alamos National Laboratory, Los Alamos, NM

Project Start Date: August 1, 2004

Project End Date: October 31, 2011

Fiscal Year (FY) 2011 Objectives

- Collaborate to develop, design, and deliver a first-class, comprehensive middle school hydrogen education program that includes: training, classroom materials, technical and best-practices exchange, and evaluation.
- Design a program to link hydrogen science and technology and the concept of a hydrogen economy to the classroom.
- Educate the 4-12th grade audience about hydrogen and fuel cell technologies to facilitate market acceptance and understanding.

Technical Barriers

This project addresses the following barriers from the Education chapter of the 2009 Fuel Cell Technologies Multi-Year Program Plan:

(A) Lack of Readily Available, Objective, and Technically Accurate Information

As awareness of hydrogen increases with increased media activity and inclusion in many state and local energy plans, there continues to be a lack of information that is readily available, accurate, and objective. Many hydrogen advocacy groups have produced educational information that in some areas would be considered more public relations information than education. This project addresses the need for educational materials that are available, objective, and accurate. Based on NEED's core principle of delivery of objective energy information, the H₂ Educate materials are reviewed by

subject matter experts, are made readily available via the Web, are delivered to educators at workshops, and are compared and contrasted with other hydrogen materials on a regular basis. This project's materials will continue to adapt as the need for additional and more robust materials becomes apparent.

(B) Mixed Messages

This project was created and continues with the intent to provide cornerstone materials that address misconceptions, provide clarity of information, and link to accurate and available information when necessary and possible. The hydrogen community continues to have disparate views on certain subjects and the key messaging to use. NEED, with review from DOE, national labs, and subject matter experts, works to provide this project with common, clear language and messaging that students, teachers, and their families find useful and appropriate for age and knowledge level. NEED works to mitigate the misinformation from the diverse messages and provide a concise message for the intended audience.

(C) Disconnect between Hydrogen Information and Dissemination Networks

NEED has capitalized on this disconnect and continues to work with various groups and organizations to become a stronger dissemination network – using local energy and education networks to deliver training and information about hydrogen to the intended audience. NEED – acting as a dissemination network – provides a conduit for valuable and accurate hydrogen information for the 4th–12th grade community. In addition, NEED has created its own information and dissemination network of 4th–12th grade educators and the education community to deliver quality hydrogen education materials and training.

(D) Lack of Educated Trainers and Training Opportunities

This project addresses the lack of educated trainers by providing professional development opportunities for teachers and energy professionals. These training opportunities provide participants with general background, foundation knowledge, and expansion information for more technically advanced audiences. NEED trains a network of trainers to deliver the information in local communities as well.

(E) Regional Differences

This project is adapted – in training methods and messaging – for local and regional differences – including proximity to hydrogen use and production. NEED's programming is locally based, with local needs – both economic and educational – considered as programs are created. Regional differences in attitudes are addressed and discussed in training programs. In

addition, regional access to hydrogen infrastructure is part of the program. Should hydrogen fueling stations, vehicles or fuel cells be nearby, the infrastructure is included in the programming.

(F) **Difficulty in Measuring Success**

The project is measuring knowledge gain among its target audience and finding good results. Educational programs often have longer term impacts that are not easily measurable in the course of a month or year. True attitude change takes a longer period of time than information gain. In all cases, educators report a minimum of a 40% knowledge increase in hydrogen knowledge upon completion of the H₂ Educate workshop. NEED is in the process of analyzing the results from a survey conducted of all educators who have participated in professional development since the beginning of the program to provide additional results for review.

Contribution to Achievement of DOE Education Milestones

This project contributes to achievement of the following DOE education milestones from the Education section of the 2009 Fuel Cell Technologies Program Multi-Year Research, Development and Demonstration Plan – Task Six: Facilitate Development and Expansion Hydrogen Technology Education for Middle and High Schools

- **Milestone 6.22:** Develop curriculum for middle schools (2Q, 2006)
- **Milestone 6.23:** Hold teacher workshops. (2Q, 2007 – 1Q, FY2012)
- **Milestone 6.24 and 25:** Revise curriculum materials (2008 and 2011)
- **Milestone 6.26 and 27:** Materials developed are in use in high schools and training is also provided to high school educators.

FY 2011 Accomplishments

- In 50% of the time estimated, the team created the middle school H₂ Educate learning module. In spite of resource constraints, the project is 100% complete with its revised scope and now is in replication and outreach to more communities. The project is scalable and can be deployed incrementally with additional resources.
- The effort has garnered additional support from a variety of partners – state energy offices, Clean Cities organizations, utilities, energy companies and others.
- Over 8,800 teachers trained.
- Training programs completed in 35 states with additional training in 2011 with extension of DOE funding.
- On average, pre-workshop survey scores were 5 out of 15 correct on the survey of hydrogen knowledge. After completing the workshop the average score was 13 out of 15 correct demonstrating a significant improvement in hydrogen knowledge as the result of the workshops.

- Preliminary survey results indicate that over 90 percent of survey participants felt that the resources made it possible to teach hydrogen more often and in more detail and that the materials increased student knowledge and understanding of hydrogen.

Introduction

In 2004, NEED and DOE launched the H₂ Educate Program for middle school and high school educators. The program included extensive curriculum development, hands-on kits for classrooms and teacher training. Using partner support from state energy offices, private industry, and trade associations, NEED extended the reach of the program to reach more teachers than originally planned.

Approach

The NEED Project brings its 30+ year history in energy education, curriculum development, teacher training, and networking efforts to H₂ Educate for middle school curriculum development, teacher training, and the expansion of hydrogen understanding and knowledge in classrooms throughout the country. NEED, with SENTECH, Inc. of Bethesda, Maryland as a key partner, launched a bold effort to exceed the DOE's expectations for a hydrogen education program in 2004 and have exceeded development calendar and outreach targets.

H₂ Educate and the activities undertaken as part of this project are the result of a collaborative effort among teachers, students, advisors, technical specialists, federal employees and professional educators. This effort brings together resources from NEED and its national partners and the DOE, to capitalize on success, resources, networking opportunities, and curriculum development and delivery capabilities. Key elements of this program are NEED's national network, a strong relationship with the National Association of State Energy Officials, and an annual budget capable of doubling the resources provided by this cooperative agreement. Making up this network are a conservatively estimated 65,000 classrooms touched by NEED materials and training each year.

Results

Results of the project continue to show success with pre-training survey results showing a 5 out of 15 correct successful response and a post-training survey result showing a 13 out of 15 correct successful response.

Workshop outreach expanded from six training programs and several hundred teachers trained in the first year of the program with over 8,800 teachers trained by 2011. NEED works to deliver the H₂ Educate curriculum

throughout the network of NEED schools and the schools they reach with educational outreach.

- Curriculum materials are available live on the NEED and DOE websites. Website statistics indicated substantial download activity. For example, hydrogen information has been added to the EIA Kid's Page www.eia.doe.gov/kids and statistics indicate 350,000 users per month.
- Addition of hydrogen information and activities to the Energy Information Association Kid's Page www.eia.doe.gov/kids (350,000 users per month).
- H₂ Educate materials have been included in NEED's curriculum redesign to provide a fresh, graphic look to the materials.
- Students and teachers show knowledge gain and deeper understanding of hydrogen knowledge.
- On post-workshop surveys, teachers indicate feeling prepared to teach the materials in their classrooms.
- Preliminary results from a survey of all educators that have participated in the program indicate that over 90 percent of educators had improved hydrogen knowledge and were more aware of hydrogen technology after the unit.

Conclusions and Future Directions

H₂ Educate programs this year continued to expand the reach of the program to middle schools throughout the country. Additional outreach via state energy offices has allowed additional programs to be delivered outside of the programs within the DOE funding for this program. NEED continues to provide hydrogen materials through the National Energy Conference for Educators, the National Science Teachers Association annual conference and a number of state science conferences throughout the country.

The Virginia Department of Mines, Minerals and Energy and the Virginia General Assembly appropriated funding to provide teacher workshops and curriculum kits and materials to schools in Virginia in execution of the Virginia Hydrogen Roundtable recommendations.

Future Directions

- An H₂ Educate session will be hosted at NEED's National Energy Conferences for Educators in July 2011.
- H₂ Educate materials will be presented at 650 local teacher workshops.
- Work with other hydrogen partners to maximize reach of programs and materials – i.e. working with infrastructure grantees to provide educational resources.
- Continue incorporation of materials and programming into NEED's existing training initiatives.
- Annually update materials with new data and provide major changes to educational community.
- The addition of H₂ Educate website for materials, links and additional information.

Deliver maximum number of hands-on resources to classrooms leveraging resources to do so. Expand partnerships with infrastructure grant recipients to provide outreach and education programming to additional communities.

Contribution to Achievement of DOE Education Milestones

This project will contribute to achievement of the following DOE milestones from the Education section of the Fuel Cell Technologies Program Multi-Year Research, Development and Demonstration Plan:

- **Milestone 26:** Develop modules for high schools. (4Q, 2007)
- **Milestone 27:** Launch high school teacher professional development. (4Q, 2008 through 3Q, 2011)

FY 2011 Accomplishments

- Publication of the two-week high school curriculum that was the major goal of this project. The curriculum is titled “Investigating Alternative Energy: Hydrogen & Fuel Cells.”
- Production of the kit that accompanies the module by LAB-AIDS, Inc.
- Redesign of the website that supports the curriculum.
- A two-day workshop for teacher professional development was held in February 2011.
- The materials were disseminated via 13 presentations to secondary science educators and hydrogen and fuel cell professionals and by display at the publisher’s booth at many of these conferences.

Introduction

This project is producing a curriculum module about hydrogen and fuel cells for high school students. A group of experienced science curriculum developers, teacher professional developers, leaders in the field of hydrogen and fuel cell technology and its application to transportation, and publishers of instructional materials are collaborating to develop and produce this curriculum as a commercial educational module. The module is intended to fit into high school courses such as physical science, chemistry, environmental science, and physics. In order to ensure that it can be used in these courses, the module addresses topics teachers usually teach and correlates to the National Science Education Standards and/or state and local standards. This project is also developing professional development workshops to prepare teachers to teach the curriculum and develop teacher leaders. Project evaluation focuses on evaluating the classroom usability of the curriculum module, students’ progress toward the intended learning goals, and the effectiveness of the professional development workshops. The past years’ work focused on completing, publishing,

Fiscal Year (FY) 2011 Objectives

- Develop, field test, revise, publish, and complete a two-week curriculum module on hydrogen and fuel cells for high school students.
- Develop and implement a professional development plan for teachers who will use the materials.
- Develop a model for collaboration among school districts, informal science centers, university scientists, local transportation agencies, and other leaders in the field.
- Disseminate the materials to a broad national audience.
- Evaluate the quality and effectiveness of the curriculum materials and professional development strategies.

Technical Barriers

This project addresses the following technical barriers from the Education section (3.9.5) of the Fuel Cell Technologies Program Multi-Year Research, Development and Demonstration Plan:

- (A) Lack of Readily Available, Objective, and Technically Accurate Information
- (C) Disconnect Between Hydrogen Information and Dissemination Networks
- (D) Lack of Educated Trainers and Training Opportunities
- (E) Regional Differences

and disseminating the curriculum module along with an equipment kit and support materials such as a digital video disk (DVD) and website.

Approach

The curriculum materials are developed and revised through a close collaboration between curriculum developers at the Lawrence Hall of Science (LHS), scientists and engineers at the Schatz Energy Research Center (SERC), experienced teacher associates, local and national field test teachers, and LAB-AIDS, Inc., an established publisher of kit-based science curriculum materials. The materials are developed by LHS with input from SERC, and classroom-tested by the developers, then by expert teachers, and finally by a broader group of teachers from local and national sites.

The module uses an issue-oriented approach to teaching concepts related to chemistry and energy topics. This approach teaches about hydrogen and fuel cells in the context of energy issues and current and future options for powering vehicles. This approach also demonstrates to students both the relevance of their science education to their lives and the role of scientists and engineers in conducting research and development to solve practical problems.

Teachers who field-test the curriculum receive two to three days of professional development prior to using the curriculum and have access to additional support as needed during the field test. The professional development workshops prepare the teachers with content background and hands-on experience for teaching the curriculum and for providing thorough feedback on the curriculum. In addition, these early professional development workshops for field-test teachers help to identify teacher leaders who will assist with dissemination and implementation of the published curriculum.

Dissemination is conducted by presentations and displays of the materials at science teacher education conferences and through the extensive networks of both LHS and LAB-AIDS, Inc.

Results

The curriculum module addresses Education technical barrier A (Lack of Readily Available, Objective, and Technically Accurate Information) by providing information about hydrogen and fuel cells in a curriculum format that is usable by teachers and students in typical classrooms. The development of the curriculum was led by the Science Education for Public Understanding Program (SEPUP), a curriculum development group that produces issue-oriented science materials that avoid advocacy. Prior to the work that took place in the past year, the module was developed through four rounds of classroom testing and revision to ensure that it works well in a wide variety of

high school settings, thus addressing barrier E (Regional Differences). At each stage of development, scientists and engineers at SERC reviewed the module for scientific and technical accuracy. Work during the past year focused on collaborating with the publisher, LAB-AIDS, Inc., and the editorial and design studio they hired to prepare the materials for publication. This involved reviewing all edits and page layouts through several iterations, and reviewing the final art that was prepared to our specifications. It also involved photo research and acquisition.

The module includes a two-week sequence of six activities that teach students about hydrogen and fuel cells. The module cover is shown in Figure 1. This cover features a photograph of the student laboratory equipment, screen shots of a simulation from the website that accompanies the curriculum, and a photograph of a hydrogen fuel cell bus provided by AC Transit. The print materials are accompanied by a kit, which includes the materials featured on the cover along with additional materials required for the laboratory and modeling activities in the curriculum module. A website provides additional material used in the module, including 1) videos of hydrogen fuel cell applications, 2) interactive computer simulations of the hydrogen fuel

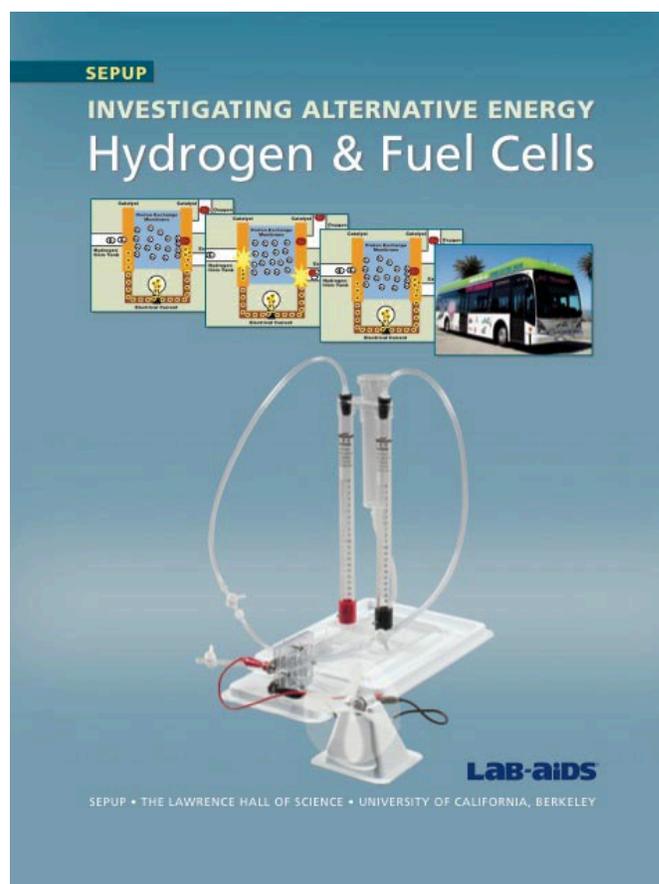

FIGURE 1. Cover of the Module – Investigating Alternative Energy: Hydrogen & Fuel Cells

cell reaction and the production of hydrogen in an alkaline electrolyzer, and 3) resources for the module's culminating activity. The video and simulations are also included on a DVD that is provided with the module, so teachers who have problems accessing the internet in their classrooms can use the DVD when teaching. The website also offers additional information about hydrogen and fuel cells for teachers, students, and the public. A pilot evaluation of student learning conducted with data collected from a sample of students during the module field-test yielded significant and educationally meaningful learning gains.

The professional development work addresses Education technical barriers C (Disconnect Between Hydrogen Information and Dissemination Networks) and D (Lack of Educated Trainers and Training Opportunities) by building on the dissemination networks of the LHS and partners and preparing teachers who will be able to provide professional development in their regions. Teachers receive professional development in the unit content, teaching approaches, science of hydrogen and fuel cells, and fuel cell applications. During the past year, one two-day professional development conference was held in Berkeley and attended by 13 teachers from Connecticut, northern and southern California, Ohio, South Carolina, and Texas. In an evaluation of the workshop, teachers gave very high ratings to all aspects of the workshop. Out of a possible high score of 5 points, teachers' average ratings were 4.73 for the curriculum, 5 for the activity presentations, and 4.85 in comparison with other professional development they have attended. Each participating teacher received a complete module and two sets of the classroom equipment.

Presentations at science teacher conferences reached over 220 teachers during the past year. These presentations targeted national and regional conferences plus conferences in states with significant fuel cell research and development and states known for good attendance at their science teacher conferences (see Figure 2). In these one to two-hour presentations, teachers were introduced to the module and information about fuel cells in the U.S. and their state,

FIGURE 2. Locations of 2010–2011 Conference Presentations

FIGURE 3. Workshop at the National Science Teachers Association Convention, San Francisco, March 2011

and conducted an activity on the fuel cell reaction that they were then given to take back to their classrooms and try out. Figure 3 shows teachers at the National Science Teacher's Association Convention conducting part of Activity 4: Modeling the Fuel Cell Reaction.

Conclusions and Future Directions

Conclusions:

- The complete curriculum module and kit are now commercially available. They have been extensively tested by high school teachers working in a variety of science subject areas (chemistry, physics, physical science, integrated science, and advanced placement environmental science), in diverse settings, and with diverse student populations.
- A professional development workshop prepared 13 teachers to implement the module in their classrooms.
- Thirteen presentations at national, state, and regional teacher workshops reached over 220 teachers. Reactions to these workshops were positive.
- Evaluations of the curriculum and teacher professional development were highly positive.

Future work will focus on:

- Preparing additional teacher support materials for the project website, including video of how to use and care for the kit equipment.
- Collaborating with the publisher and other partners to disseminate the curriculum, develop teacher leaders, and support new users of the program.

X. MARKET TRANSFORMATION

X.0 Market Transformation Activities

Introduction

The Market Transformation sub-program is conducting activities to help promote and implement commercial and pre-commercial hydrogen and fuel cell systems in real-world operating environments and to provide feedback to research programs, U.S. industry manufacturers, and potential technology users. One of the sub-program's goals is to achieve sufficient manufacturing volumes in emerging commercial applications that will enable cost reductions through economies of scale, which will help address the current high cost of fuel cells (currently the capital and installation costs of fuel cells are from five to six times higher than incumbent technologies¹). These early market deployments will also address other market acceptance factors, resulting in further expansion of market opportunities.

Current key objectives of the Market Transformation sub-program are to build on past successes in material handling equipment, such as lift trucks, and emergency backup power applications that were part of the Recovery Act, by exploring potential and emerging applications for market viability. Fiscal Year (FY) 2011 activities were primarily focused on initiating 10 diverse projects, using FY 2010 appropriations. These projects are highly leveraged, with an average of more than half of the projects' funds being provided by DOE's partners. Partners providing resources to these projects have shown a high level of interest in exploring these applications and markets, and this level of industry interest is very promising for the potential growth of the domestic fuel cell industry.

Goals

Market Transformation activities provide financial and technical assistance for the use of hydrogen and fuel cell systems in early market applications, with the key goals of achieving sales volumes that will enable cost reductions through economies of scale, supporting the development of a domestic industry, and providing feedback to testing programs, manufacturers, and potential technology users.

Objectives²

- Advance the knowledge and expertise regarding the use of fuel cells for waste-to-energy systems, shipboard auxiliary power units (APUs), and aviation applications through targeted testing and evaluation efforts in coordination with the Technology Validation sub-program and in partnership with Department of Defense (DOD) and civilian agencies such as the Department of Agriculture and the Federal Aviation Administration by evaluating design requirements for aircraft APUs by 2012, shipboard APUs by 2013, and waste-to-energy fuel cells by 2014.
- By 2013, establish baseline energy efficiency and reliability performance metrics for commercially available emergency backup power, material handling, and light commercial/residential power fuel cell systems and provide feedback to component suppliers regarding cost reduction opportunities.
- By 2014, test emerging approaches to grid management using renewable hydrogen storage and fuel cell systems, in coordination with the DOE Office of Electricity Delivery and Energy Reliability.
- By 2015, develop and launch energy efficiency and reliability certification programs for fuel cells.
- By 2016, Identify lessons learned from existing policies and regulations and promote the development of effective and applicable incentives for hydrogen and fuel cell technologies.
- By 2020, enable capital equipment cost of fuel cell-powered lift trucks and emergency backup power systems to be on a par with conventional technologies.

FY 2011 Status

Fuel cells have been enjoying growing success in key early markets, particularly in material handling (e.g., forklift) and backup power applications. The Program's early market deployment efforts—including Market Transformation funding and Recovery Act funding—have successfully catalyzed a significant level of market

¹ *Catalog of CHP Technologies*, U.S. Environmental Protection Agency, December 2008, www.epa.gov/chp/basic/catalog.html.

² Note: Targets and milestones are under revision; therefore, individual progress reports may reference prior targets.

activity in these areas, which has been accompanied by substantial reductions in the price of fuel cells. The sub-program is actively pursuing additional opportunities for effective stimulation of market activity. Ongoing activities and additional areas of interest include the following:

- **Backup Power:** A joint effort has been initiated by DOD's U.S. Army Corps of Engineers and the Program to install 18 emergency backup power fuel cell systems at eight DOD locations. Data will be collected and analyzed during a five-year period of operation.
- **Hydrogen Bus Deployment:** The Program is continuing to support the deployment of hydrogen-powered internal combustion engine buses produced by Ford Motor Company. The buses are being used at national laboratories and federal facilities, for special events, campus tours, new employee orientations, and as part of shuttle bus fleets.
- **Combined Heat and Power (CHP) Feasibility Studies:** Eleven technical, site-specific feasibility studies have been completed. The resulting reports, which assess the installation and operation of distributed power or CHP fuel cells at DOE locations, have been provided to U.S. fuel cell manufacturers; discussions about specific siting and financing options are underway at several sites, including Los Alamos National Laboratory and the National Renewable Energy Laboratory.
- **Material Handling Equipment (MHE):** As a complement to the hydrogen fuel cell forklift deployments currently underway, the sub-program is investigating the use of direct methanol fuel cell (DMFC) technologies. DMFC MHE will provide the same operational benefits as hydrogen-powered fuel cell MHE, with significant additional benefits from the use of a liquid fuel, including reduced infrastructure costs, high energy density, and low overall fueling costs. Other activities involving hydrogen-fueled lift trucks are ongoing, including collaboration with the Defense Logistics Agency (DLA). The DLA's Eastern Distribution Center now has 55 fuel cell-powered lift trucks. Recent deployments of fuel cell-powered stand-up lift trucks have completed the portfolio of MHE classes that have been retrofitted, which could lead to the complete elimination of battery infrastructure at DOD sites that fully convert to fuel cell power for their MHE needs.
- **Mobile Lighting:** The sub-program is exploring the potential for expanded use of fuel cells for mobile lighting, which is commonly used for road maintenance, general construction, and large outdoor events. Unlike conventional diesel-based systems, fuel cells offer the benefits of nearly silent operation, with no harmful exhaust emissions. Working with manufacturers of fuel cells and mobile lighting equipment, the Program has supported the design, construction, and testing of fuel cell power mobile lighting prototypes (Sandia National Laboratories). Demonstration and testing was conducted at a Boeing Manufacturing Plant, NASA Kennedy Space Center, Caltrans, Paramount Pictures/Saunders Electric, and the San Francisco International Airport.
- **Market Analysis and Deployment Tools:** The sub-program continues to pursue opportunities for collaboration through the DOE-DOD memorandum of understanding, including two projects that have analyzed the technical feasibility of using fuel cells for auxiliary power onboard commercial passenger airliners, addressing both low-temperature polymer electrolyte membrane (PEM) fuel cells (Sandia National Laboratories), and high-temperature ceramic-type fuel cells (Pacific Northwest National Laboratory).
- **Micro CHP:** To document market viability of fuel cells for small facilities, the sub-program is working with fuel cell manufacturers and their partners to demonstrate CHP systems at several light commercial facilities. Baseline technical performance models have been established, the most competitive projects have been selected, and a final contract has been issued with ClearEdge Power to provide up to 38 fuel cells at up to 10 locations. A key objective of this work is to obtain performance data on these systems over the course of several years.
- **Green Communities:** The sub-program is working to help communities incorporate hydrogen and fuel cell technologies into their existing energy efficiency, sustainable energy, and greenhouse gas reduction plans. A decision-matrix tool has been developed and has been used to identify five community types as having high potential benefits for deployment of hydrogen and fuel cells. Actual communities will be selected through the Sources Sought and Request for Proposal processes. The sub-program's efforts in this area also include identifying opportunities for education and outreach to increase the public's awareness of hydrogen and fuel cell technologies.
- **Big Island of Hawaii Hydrogen Energy Storage Project:** In partnership with the Naval Research Laboratory and the University of Hawaii's Hawaii Natural Energy Institute, the sub-program is supporting

the demonstration of using a hydrogen energy storage system as a grid management tool. While hydrogen produced from the system could be used for a variety of value-added products, the initial phase of the project will use the hydrogen to fuel two Ford E-450 shuttle buses operated by the County of Hawaii Mass Transportation Agency.

- **South Carolina Landfill Gas Purification Project:** The sub-program is demonstrating the business case and technical viability of using landfill gas (LFG) as a source of renewable hydrogen production, using BMW's assembly plant in South Carolina as the host site. Should such a scale-up operation prove viable, it would represent a first-of-its-kind LFG-to-hydrogen production project in the nation, and it would serve as a model for future adoption of renewable biogas as a feedstock for hydrogen production.

FY 2011 Accomplishments

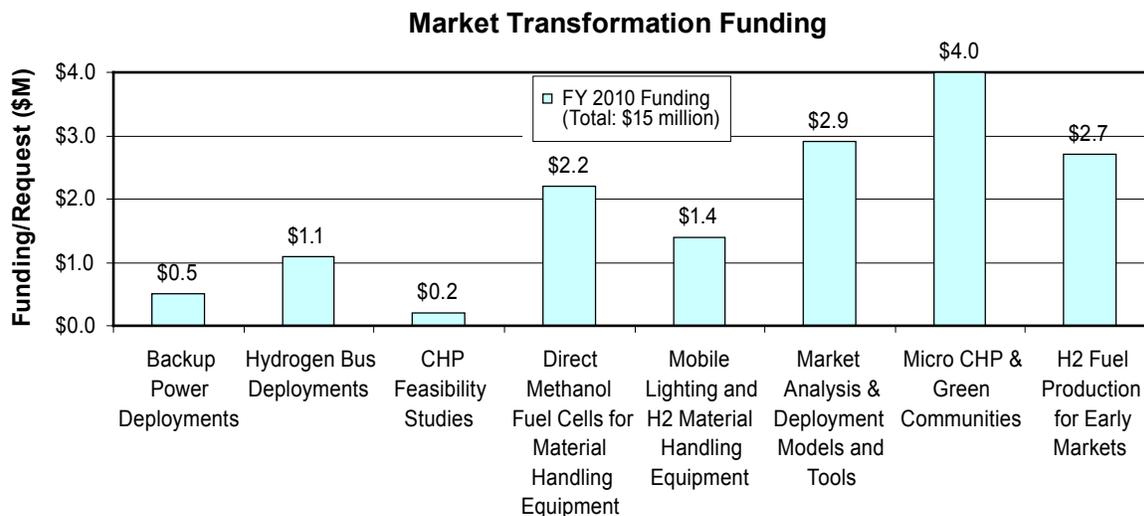

In FY 2011, the sub-program developed deployment tools and business cases for various fuel cell applications, conducted public outreach activities, and analyzed and tested potential new early markets in mobile lighting, DMFC-powered lift trucks, and auxiliary power. The following are some of the key milestones the sub-program achieved in FY 2011:

- Created a federal fuel cell user's forum for backup power fuel cells deployed at Army, Navy, NASA, and national laboratory sites.
- Completed design of a fuel cell mobile lighting system that combines high-pressure (5,000 psi) hydrogen storage, efficient plasma lighting, and a 5-kW PEM fuel cell; built five fuel cell mobile lights that are being field tested at industry and government installations; and expanded public awareness of the technology by using fuel cell mobile lighting at the 2011 Golden Globe Awards and 2011 Grammy Awards.
- Completed deployment and outreach activities for 22 hydrogen-powered buses at federal facilities and national laboratories. The buses were shown to thousands of attendees at several events such as the "Taste of Colorado" in Golden, Colorado; the Innovation for Green Advanced Transportation Excellence's National Energy Systems Technology Incubator opening in Livermore, California; the Southwest Region Fleet Transportation Regional Managers Conference in Camp Pendleton, California; "Expanding Your Horizons in Math and Science" in San Ramon, California; and at multiple Earth Day Celebrations in California, Hawaii, and South Carolina.
- Developed a decision matrix tool that highlights the most promising community types for hydrogen and fuel cell system deployment projects; and used this tool to rank 56 community types, with the top five identified as "high-potential" deployment sites for hydrogen and fuel cell systems.
- Published a business case for a utility with renewable resources, in which excess or "spilled" wind power is used to produce hydrogen via electrolysis for later use in fuel cell power generation; and updated utility energy storage model to include purchase of curtailed wind energy. A key conclusion is that hydrogen produced from un-dispatchable renewable power can be used for grid management and high-value products, such as transportation fuel.
- Developed overall system requirements, specifications, and a conceptual system design for a hydrogen energy storage system to be used as a grid management tool.
- Built, tested, and delivered 75 DMFCs to customer warehouse sites for use and testing in class-III material handling equipment.
- Completed a feasibility study of a LFG-to-hydrogen project. A key finding is that LFG-to-hydrogen production needs to be at a rate of more than 500 kg/day to be competitive with vendor-supplied hydrogen.
- For aircraft auxiliary power applications, analyzed the electrical system using a PEM fuel cell on a direct current bus that will reduce power conversion losses and reduce in-flight jet fuel consumption; obtained extensive information from Boeing on the 787 electrical system, including generation and distribution systems, load profiles, and fuel consumption. A key finding was that for some hotel power loads—such as galley and peak-power needs—the use of a PEM fuel cell APU could save up to 30% of the jet fuel these loads would normally consume (which would result in a reduction of 20,000 metric tons of CO₂ emissions annually, for a fleet of 1,000 airplanes).³

³ Pratt, J. W., et al., "Proton Exchange Membrane Fuel Cells for Electrical Power Generation On-Board Commercial Airplanes," Sandia National Laboratories, May 2011, http://www1.eere.energy.gov/hydrogenandfuelcells/pdfs/pem_onboard_airplane.pdf.

Budget

No funding was requested for Market Transformation in FY 2011 or FY 2012. With the market successes that have been achieved by fuel cells in lift trucks and backup power applications as a result of FY 2009 and Recovery Act funding, the focus of FY 2010 funds was on new applications, such as micro CHP and mobile lighting applications.

FY 2012 Plans

In FY 2012, the sub-program will continue to document lessons learned associated with previously funded projects, including the strategies developed for market entry and for risk management with respect to safety, environmental, and siting requirements. Planning for business case analysis and case studies will be initiated. Collection and evaluation of data from these projects will provide the basis for verifying the business cases for various early market fuel cell systems, as well as providing an assessment of the performance of these integrated systems. Data will be made publicly available so that more customers will become aware of the benefits of integrated hydrogen and fuel cell systems. In addition, a near-term priority will be to continue collaborating with other federal agencies—in accordance with existing interagency cooperative agreements such as the DOE-DOD memorandum of understanding—to increase the use of fuel cells in market-ready applications and to increase awareness of the benefits of these deployments.

Project Start Date: March 15, 2010
Project End Date: September 30, 2011

Fiscal Year (FY) 2011 Objectives

- Design a fuel cell mobile lighting system to replace current diesel-based systems.
- Organize a project development team that includes new technology holders, mass manufacturing partners and end users.
- Build five fuel cell mobile lights, field test with deployment partners.
- Design a commercial system, produce a commercially available product.
- Deploy the technology in high-profile events to increase public awareness of hydrogen fuel cell technology.

Technical Barriers

This project addresses the following technical barriers assigned to this project:

- (A) System Weight and Volume
- (B) Cost
- (C) Efficiency

Technical Targets

- Promote exposure of public to H₂/fuel cells (trade shows, high profile events).
- Promote use of H₂/fuel cells in aviation (use at San Francisco International Airport [SFO], in Boeing manufacturing plant).
- Promote use of H₂/fuel cells in entertainment (use at Paramount Pictures, award shows).
- Promote use of H₂/fuel cells in construction (use with California Department of Transportation [Caltrans]).

- Promote use of H₂/fuel cells in high technology (use at National Aeronautics and Space Administration (NASA) Kennedy Space Center).

FY 2011 Accomplishments

- Designed a fuel cell mobile lighting system combining high pressure (5,000 psi) hydrogen storage, efficient plasma lighting and a 5 kW proton exchange membrane (PEM) fuel cell.
- Designed a hybrid fuel cell mobile light incorporating both high pressure (5,000 psi) hydrogen tankage and an interstitial metal hydride tank.
- Organized a project development team that includes new technology holders, mass manufacturing and end users. The project team includes Multiquip Inc., Stray Light Optical Technology, SFO, Ovonic Hydrogen Systems, Alteryg Systems, Golden State Energy, Caltrans, the California Fuel Cell Partnership (CaFCP), Lumenworks, Boeing, Luxim, and Saunders Electric.
- Built five fuel cell mobile lights, being field tested at Boeing Manufacturing Plant, NASA Kennedy Space Center, Caltrans, Paramount Pictures/Saunders Electric and at SFO.
- Promoted exposure of public to H₂/fuel cells (use of system at 2010 Oscars, 2011 Golden Globes, 2011 Grammy Awards and the 2011 Screen Actors Guild Award Show).
- Achieved a fuel cell mobile light that will run for 66 hours, with a greater than 73% reduction in greenhouse gas emissions (GHG) emissions compared to current technology. System is significantly quieter than current diesel technology.
- Designed a commercial fuel cell mobile light system, now commercially available by Multiquip Inc. as the H₂LT system.

Introduction

The vast majority of mobile light-to-medium construction equipment is based on combustion of diesel fuel. Equipment examples include diesel-fueled mobile lighting towers, portable power generators, mobile water pumps and concrete-masonry equipment. Such equipment is commonly used for road maintenance, general construction and other industrial applications. As diesel-based systems, the current equipment technology suffers from well-known problems including release of toxic air contaminants and particles into the air (threatening human health), and also emission of CO₂ and other GHG

(contributing to global climate change). These diesel systems are also comparatively inefficient in their use of energy, as well as distractingly loud, which is a safety issue for those using them. The goal of this project has been to replace diesel-powered mobile lighting systems with clean, energy efficient new technology based on fuel cell power. Our goals in this project are not to perform a demonstration, but rather design, build, test and commercialize a fuel cell-based mobile lighting system that customers can buy to start reducing GHG and other criteria pollutants.

Approach

After an initial design of the fuel cell mobile light, we put together a development team comprised of new technology holders, mass manufacturing and end users. The project team includes the new technology holders Altery Systems (PEM fuel cells), Luxim, Lumenworks and Stray Light Optical Technologies (plasma lighting), hydrogen systems storage and integration (Sandia) and metal hydride hydrogen storage (Ovonic Hydrogen Systems). The mass manufacturing partners are Multiquip Inc. (the largest manufacturer of rental construction equipment), Altery Systems (mass manufacturer of PEM fuel cells) and Luxim, Stray Light Optical Technologies and Lumenworks (manufacturers and designers of plasma light technology). End users include the SFO, Caltrans, Boeing and Saunders Electric Inc. Golden State Energy made critical contributions to the development of the project team, and the CaFCP has been an important advisor on hydrogen refueling stations/technology, and on the current codes and standards associated with hydrogen fueling. Special thanks go to Paramount and NASA Kennedy Space Center who will also be deploying the technology.

Our work has been focused on designing, building, and deploying a fuel cell mobile light system to replace existing diesel-powered lighting towers commonly seen along highways in road maintenance work. After deploying the mobile light, the fuel cell technology is being proliferated into a newly created Multiquip Inc. fuel-cell-based product line called EarthSmart™.

Results

The first result was the design of a near-commercial “Beta” unit that improved the operating characteristics beyond the “Alpha” system that was built prior to DOE funding of the project. The Beta unit utilizes four commercially available 5,000 psi composite hydrogen tanks, along with eight plasma light fixtures (from Luxim, Stray Light Optical Technologies and Lumenworks). The 5 kW PEM fuel cell (Altery) was incorporated, along with full “near-commercial” integration of the electronics for the fuel cell and lighting controls. The Beta system was designed by Sandia, Multiquip, Altery and Stray Light Optical Technologies, with the system integrated by Multiquip in its Boise, Idaho manufacturing facility. It is worth noting that Multiquip had no prior manufacturing experience with

high-pressure gas, fuel cells or hydrogen systems in general. Early on, a training class in high-pressure systems design, hydrogen safety, and hydrogen and fuel cell technology took place at Altery Systems on November 14, 2010. Attendees included Multiquip manufacturing management and staff, along with other project partners.

Sandia felt that it was important for the project partners (especially Multiquip) to have some experience with metal hydride hydrogen storage technology. As a result, Sandia designed a hybrid fuel cell mobile light system that combines high-pressure storage with one metal hydride tank (from Ovonic). The design incorporates and accommodates thermal management issues that arise with metal hydride technology, namely heat needing to be supplied to the metal hydride material from fuel cell waste heat, and heat needing to be removed from the material when the metal hydride material is recharged with hydrogen. Construction of a hybrid unit will be complete by Sandia and Multiquip in August of 2011.

The first construction activity was an upgrade of the Alpha system that had been built prior to DOE funding. The upgrade of the system included a more commercial looking cabinet, and the introduction of weatherproof lighting housings. This upgrading allowed the Alpha system to be a field-deployable unit from which early learning could be gathered. The Alpha system was deployed at the NASA Kennedy Space Center in support of the last two shuttle launches. A picture of the Alpha system at the Kennedy Space Center is shown in Figure 1. Eventually the Alpha system at the NASA Kennedy Space Center will be replaced by a Beta system which has twice the endurance of the Alpha system, and more commercial integration of the fuel cell and lighting controls.

Endurance data on the Alpha system was collected by Sandia at its Livermore, California facility. Monitoring the power consumed by the lighting, hydrogen pressure, and the system endurance, results indicated that a commercial fuel cell mobile light using plasma light technology could last 66 hours on a single fueling. This is somewhat longer than the typically 50-hour duration of diesel-based systems. Using the test data, a PEM fuel cell efficiency of 47% was observed.

The first Beta fuel cell mobile light system was used to introduce the H₂ fuel cell mobile light to the power generation community at PowerGen 2010 in Orlando, Florida on December 13, 2010. The response was excellent from the power generation community particularly with regard to its quiet operation, and ability to be used indoors. The Beta system was also shown to the realm of construction equipment at the World of Concrete Show in Las Vegas, Nevada on January 17, 2011. At this show, the Beta fuel cell mobile light, now termed H₂LT (hydrogen light tower) as an official Multiquip product, received the prestigious 2011 Most Innovative Product Award, World of Concrete Editors Choice Award for General Tools and Equipment. A picture of the Beta unit from the World of Concrete Show is shown in Figure 2.

(Photo courtesy of Lennie Klebanoff Productions)

FIGURE 1. Deployment of Alpha Fuel Cell Mobile Light at the NASA Kennedy Space Center, 4/21/2011, Cape Canaveral Florida

The second Beta unit was constructed and delivered to Caltrans on April 19, 2011. Caltrans, using its own internal resources, is having the H₂LT tested in a comprehensive series of tests conducted by the University of California, Davis (UC Davis) Advanced Highway Maintenance and Construction Technology Research Center. The California Highway Patrol is also participating in this characterization project. The UC Davis team is characterizing the performance of the H₂LT with regard to lighting efficacy (illumination uniformity, glare, and visibility), emissions (compared with diesel system), refueling efficacy (refueling time, ease of operation, costs) and design robustness (engineering analysis of performance, other testing). Caltrans will use its Beta system in its road construction work, graffiti removal work, as well as at a snow-chain checkpoint in the Sierra Mountains of Northern California to test its use in cold weather.

Boeing received its Beta unit in late July of 2011. The unit will be used at Boeing's Paine Field operations, as well as inside its aircraft manufacturing facility in Everett, Washington. The Paine Field operations will allow the unit to be tested against rain, sleet, and cold foggy conditions which are present at that location in the winter months.

(Photo Courtesy of Lennie Klebanoff Productions)

FIGURE 2. The Beta Fuel Cell Mobile Light at the World of Concrete Show, January 17, 2011, Las Vegas, Nevada

Similarly, the Hybrid Unit which will be deployed at SFO will be severely tested against the rain, wind, and fog present at that facility which often leads to very early rusting of equipment in use on the airfield. The Beta system which will be eventually deployed at the NASA Kennedy Space Center will be exposed to extreme heat, humidity and salty air at the Cape Canaveral Florida location. Finally, testing of the fuel cell mobile light with Saunders Electric and Paramount Pictures will assess its usefulness in the entertainment industry. In particular use of the unit for remote Paramount film shoots will allow Multiquip to assess the sound conditioning which is really required for the unit. Up until this point, units have not been sound conditioned in any way, yet the response from potential customers has been that the naturally quiet fuel cell technology is already remarkably better than noise from diesel-based systems. The project may attempt to sound condition a unit to see just how low the noise can be brought on the H₂LT technology.

The Alpha version of the fuel cell mobile light was used at the 2010 Academy Awards on March 7, 2010, at the invitation of Saunders Electric Inc. who provides all the portable power for the Oscars. For this event, the unit was used in the construction of the red carpet by construction

(Photo courtesy of the Academy of Motion Picture Arts and Sciences)

FIGURE 3. Use of the Alpha Fuel Cell Mobile Light at the 2010 Academy Awards, Red Carpet Construction, 3/6/2010

crews of the Academy of Motion Picture Arts and Sciences, and used the day of the event to provide lighting and power at a security entrance to the red carpet. A picture from the Academy Awards red carpet preparations is shown in Figure 3. The upgraded Alpha was also used at the 2011 Golden Globe awards in Los Angeles California on January 16, 2011 for the red carpet construction, as shown in Figure 4. Saunders Electric also deployed the technology at the 2011 Screen Actors Guild Award show on January 30, 2011, and at the 2011 Grammy Awards on February 13, 2011.

Conclusions and Future Directions

The fuel cell mobile light project has allowed the design, construction, deployment and commercialization of the first fuel cell technology used in the construction equipment realm. The response from the construction, entertainment and power community has been excellent, with recognition of the project from a number of sources and use of the technology in a number of high-profile events. The H₂LT system is the first product in a newly formed EarthSmart™ product line from Multiquip Inc. Future directions for

(Photo courtesy of Ron Roy Productions)

FIGURE 4. Use of the Alpha Fuel Cell Mobile Light at the 2011 Golden Globe Awards, Red Carpet Construction, January 16, 2011

could involve the construction of fuel cell versions of other construction equipment, for example portable power generators, and air compressors used in construction.

Special Recognitions

1. 2011 DOE Hydrogen and Fuel Cells Program R&D Award, "In recognition of outstanding contributions to Fuel Cell Market Transformation Activities," for Fuel Cell Mobile Light Project, presented to Lennie Klebanoff, Sandia National Laboratories, May 11, 2011.
2. U.S. Congress Certificate of Special Recognition, 2011 Dream Makers and Risk Takers Award Winner, presented to Lennie Klebanoff and Terry Johnson (Sandia) "in recognition of outstanding and invaluable service to the community," for Fuel Cell Mobile Light Project, issued by John Garamendi, Member of U.S. Congress, March 29, 2011.
3. 2011 Dreamers and Risk Takers Technology Award, Livermore CA Chamber of Commerce, presented to Lennie Klebanoff and Terry Johnson (Sandia) for Fuel Cell Mobile Light Project, March 29 2011.
4. 2011 Most Innovative Product Award, World of Concrete Editors Choice Award for General Tools and Equipment, Fuel Cell Mobile Light (H₂LT), presented to Multiquip Inc.

5. 2010 Federal Laboratory Consortium Award “Mid-Continent Region” for “Notable Technological Achievement”, Sandia National Laboratories, Fuel Cell Mobile Light Project, September 2010, presented to Lennie Klebanoff.

Sandia National Laboratories is a multi-program laboratory managed and operated by Sandia Corporation, a wholly owned subsidiary of Lockheed Martin Corporation, for the U.S. Department of Energy’s National Nuclear Security Administration under contract DE-AC04-94AL85000.

X.2 Economic Analysis of Large-Scale Hydrogen Storage for Renewable Utility Applications

Susan Schoenung
Longitude 122 West, Inc.

SNL: Jay Keller
Phone: (925) 294-3316
E-mail: jokelle@sandia.gov

Contract Number: SNL 1024882

Project Start Date: May 2010
Project End Date: November 2011

- Performed sensitivity analyses, primarily around the operating times and economic factors.
- Established a utility with renewables business case, in which excess, or “spilled” wind power is used to produce hydrogen via electrolysis. Large-scale storage stores the hydrogen for later use in fuel cell power generation. The excess power is used at no cost. In discussions with a number of utilities and grid operators, the case of excess wind for a period up to six hours was established for analysis.
- Made benefit/cost estimates based on the present value of costs and benefits, where benefit values are recently published in the utility energy storage literature.

Introduction

Previous work by this author [1,2] and others [3] has explored the potential use by the electric utility industry of hydrogen produced and stored in bulk. These studies show promise in some applications, especially where large scale is demanded and particularly in conjunction with intermittent energy resources such as wind.

The use of hydrogen will compete with other energy storage technologies, including modular systems, such as batteries, and other large-scale systems such as compressed air energy storage and pumped hydro storage. The major weakness in the hydrogen system is the relative inefficiency of energy conversion through the electrolysis and fuel cell subsystems. The major advantage is low storage cost and high volumetric energy density. The use of “spilled wind” presents an opportunity to install large scale hydrogen storage.

Approach

The approach to this work proceeds along the following steps:

- Assume a design concept in which energy storage is connected to an electric grid that includes power generation from wind. The storage system is charged from the grid and discharged back to the grid.
- Calculate the capital cost of the energy storage systems, dependent on the size of the storage system, i.e., the number of hours of stored energy for full power discharge. Cost assumptions for the hydrogen system components and other storage technologies are shown in Tables 1 and 2 [4,5].

Fiscal Year (FY) 2011 Objectives

- Model bulk hydrogen storage integrated with intermittent renewable energy production of hydrogen via electrolysis for utility applications.
- Determine cost-effective scale and design characteristics.
- Explore potential attractive business models.

Barriers

This project addresses the following barriers assigned to this project:

- Non-technical barriers to commercialization of hydrogen and fuel cells.
- Ensure continued technology utilization growth for domestically produced hydrogen and fuel cell systems.
- Enable greater penetration of clean renewable energy production while addressing the market for large-scale storage of hydrogen and hydrogen technologies.

FY 2011 Accomplishments

- Updated utility energy storage model to include purchase of curtailed wind energy.
- Updated costs for fuel cell and hydrogen systems and other storage technologies and compared. Other technologies are pumped hydro storage, compressed air energy storage, advanced lead-acid batteries, sodium sulfur batteries and flow batteries.

TABLE 1. Cost and Efficiencies of Hydrogen Technologies in this Study

	Current Efficiency	Target Efficiency	Current Cost - Mid	Target Cost - Low
Electrolyzer	73.5%	75%	340 \$/kW	125 \$/kW
Gas Storage	Not Applicable	Not Applicable	15 \$/kWh	2.5 \$/kWh
Underground Storage	Not Applicable	Not Applicable	0.3 \$/kWh	0.3 \$/kWh
Fuel Cell	55%	58%	500 \$/kW	100 \$/kW

TABLE 2. Cost and Performance Assumptions for Energy Storage Technologies

Technology	Power Subsystem Cost \$/kW	Energy Storage Subsystem Cost \$/kWh	Round-Trip Efficiency %	Cycles
Advanced Lead-Acid Batteries (2,000 cycle life)	400	330	80	2,000
Sodium/Sulfur Batteries	350	350	75	3,000
Flow Batteries	400	400	70	3,000
Compressed Air Energy Storage	700	5	N/A (70)	25,000
Pumped Hydro	1,200	75	85	25,000

- Calculate the annual life cycle cost, including the costs of operations and maintenance, charging electricity, replacement costs, and capital charge.
- Convert to present value for comparison with benefits estimates from published literature.

Results

Results include comparison of annualized costs for energy storage technologies in “load-leveling” mode. This required an update of the energy storage cost model and the cost estimates for hydrogen systems and other technologies. The economic model was then modified for the “spilled wind” application. Figure 1 shows the comparison of hydrogen at medium and low hydrogen cost estimates with other technologies for the spilled wind case. If spilled wind is available free of charge for six hours each day (or night), the hydrogen approach is competitive with other technologies, even compressed air energy storage (CAES).

The present value of costs is compared with the present value of benefits estimated for electric utility value propositions. Figure 2 shows the present value (PV) of costs for load-leveling and spilled wind cases for medium and low-cost hydrogen systems on a \$/kW basis, compared with the present value of benefits based on a study published by Sandia National Laboratories (SNL) for the DOE Energy Storage Systems program [5]. These results show a positive benefit/cost ratio if capacity credits are added to time-shift benefits.

Figure 3 shows the same comparison on a \$/kWh basis, where benefits have been estimated by the Electric Power

Annual cost of Bulk energy storage systems charged with 6-hr free spilled wind power, 20-yr systems, 365 days/yr

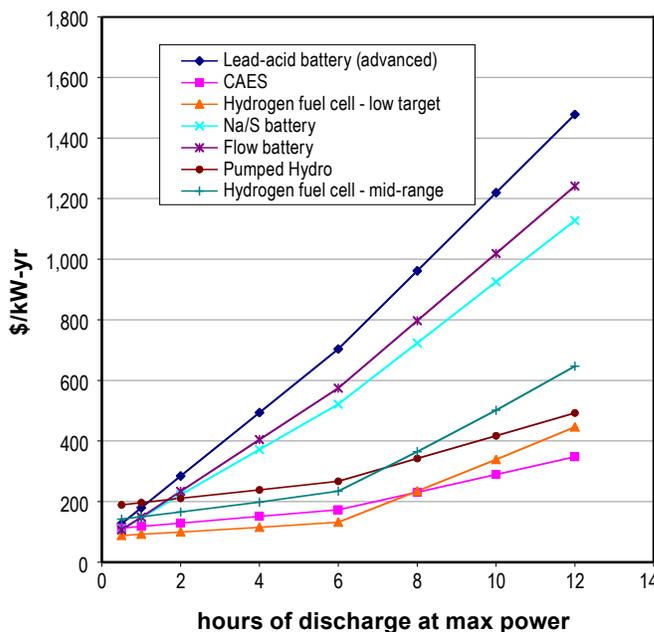

FIGURE 1. Annualized Cost of Energy Storage Systems for Spilled Wind Case

Research Institute (EPRI) [6]. In this case, the energy capacity credit is very large, so that even the medium cost system has a positive benefit/cost ratio. This represents an attractive opportunity for bulk hydrogen storage with wind.

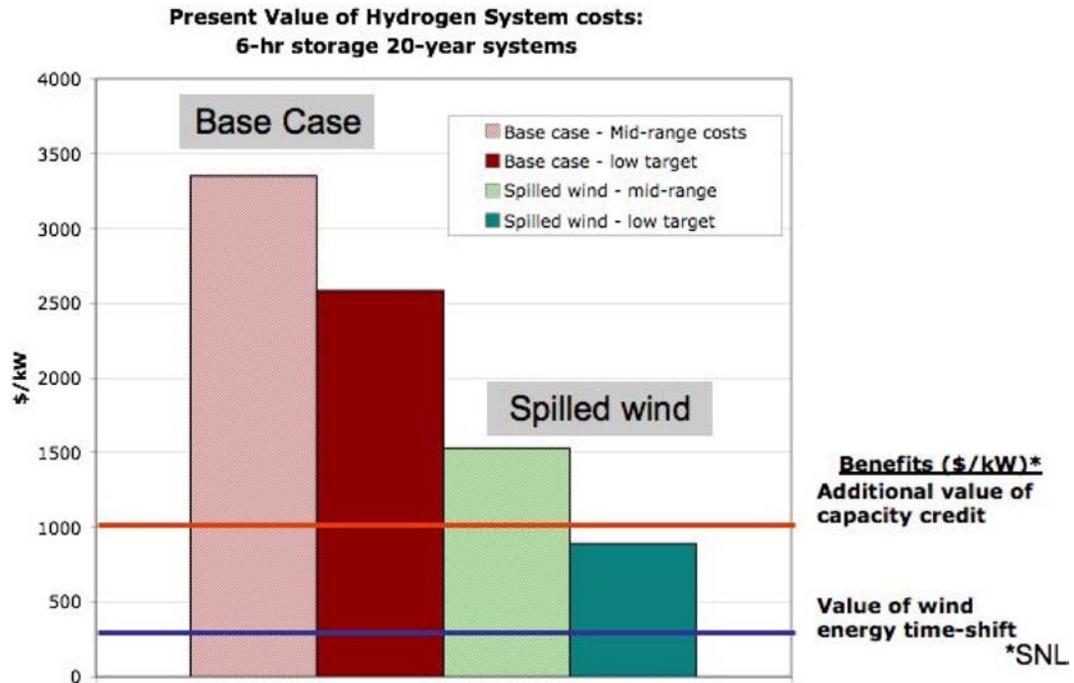

FIGURE 2. Present Value of Costs and Benefits on a \$/kW Basis

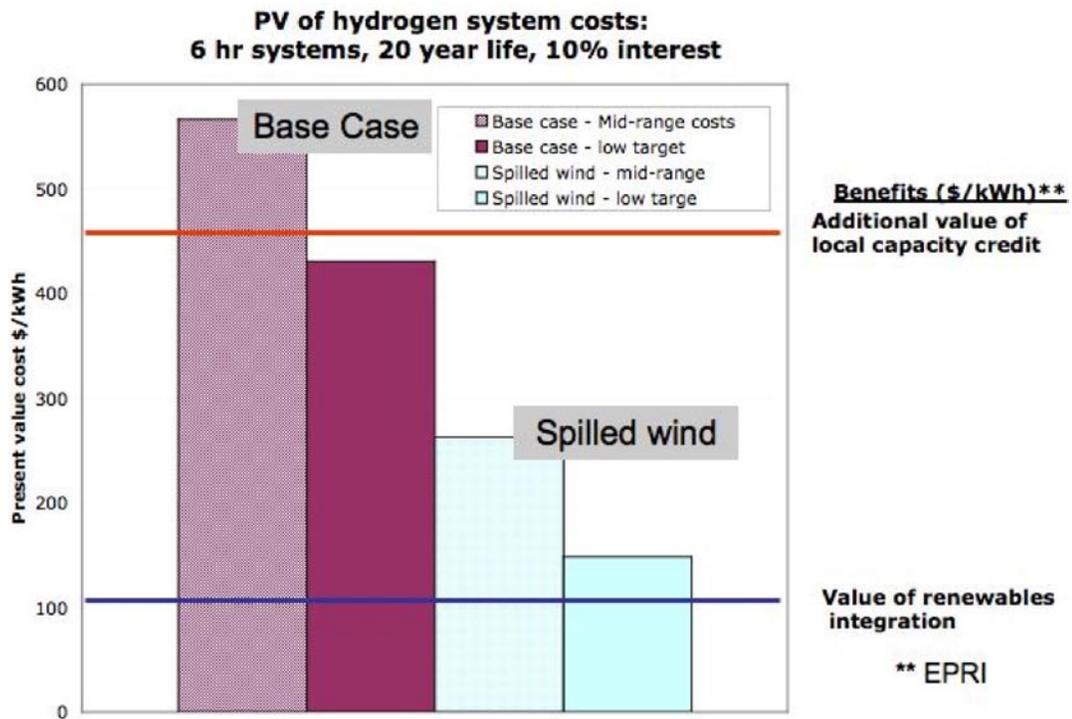

FIGURE 3. Present Value of Costs and Benefits on a \$/kWh Basis

Conclusions and Future Directions

Some conclusions from this study include the following:

- Hydrogen energy storage is an ideal match for renewables of all scales, especially large-scale wind, and particularly when excess wind is available off-peak.
- Hydrogen with renewables is effective for reducing greenhouse gases from power generation.
- Underground storage offers opportunities to store hydrogen because it can provide high capacity at cost competitive rates.
- Market opportunities for bulk hydrogen storage need development.

Recommendations for further work include:

- Add scaling considerations to utility business model, considering the spectrum of value propositions, both at much large scale of storage, and smaller scale of storage.
- Add location considerations to cost and benefit analysis.
- Build third-party (non-utility) opportunities into business model.
- Continue discussions and deliberations with commercial interests, market potential.

Hydrogen Safety, Section 3.8.4

(H) Lack of Hydrogen Knowledge by Authorities Having Jurisdiction

FY 2011 Accomplishments

- Developed overall system requirements and specification.
- Developed conceptual system design.
- Progressed legal agreements among project participants, including resolution of liability, indemnification, and insurance issues and requirements.
- Applied for additional funding from the State of Hawaii to augment DOE funding.
- Prepared and issued a request for proposal for the supply of the hydrogen system.
- Conducted a bidders' conference in Washington, D.C.
- Bids received and evaluated.
- Hydrogen system supplier selected.
- Initiated site design with infrastructure contractor.

Fiscal Year (FY) 2011 Objectives

- Demonstrate dynamic operation of electrolyzers as a grid management tool to mitigate the impacts of intermittent renewable energy on the grid.
- Characterize performance/durability of commercially available electrolyzers under dynamic load conditions.
- Provide hydrogen to fuel two Ford E-450 internal combustion engine shuttle buses for local community bus service operated by the County of Hawaii Mass Transit Agency.
- Conduct performance/cost analysis to identify benefits of integrated systems including grid services and off-grid revenue streams.

Technical Barriers

This project addresses the following technical barriers from the indicated sections of the April 2009 edition of the Fuel Cell Technologies Program Multi-Year Research, Development and Demonstration Plan:

Hydrogen Production, Section 3.1.4

- (I) Grid Electricity Emissions
- (J) Renewable Energy Generation Integration
- (Q) Testing and Analysis

Technology Validation, Section 3.6.4

- (H) Hydrogen from Renewable Resources

Introduction

While solar and wind resources offer a major opportunity for supplying energy for electricity production and delivery systems, their variability and intermittency can raise significant interconnection challenges. At very high penetration levels, grid-operational issues caused by these renewable sources are a challenge and can lead to curtailment of the renewable resource, adding additional cost to the electricity supplied by these renewable resources. Hydrogen production through electrolysis may provide the means to mitigate curtailment and grid management costs by serving as a controllable load that varies in response to frequency signals from the grid. Such dynamic operation of the hydrogen production can provide the power producer or systems operator with increased options for coordinating system loads. The renewable hydrogen product can also create new revenue streams for the power producers through the sale of hydrogen products to customers outside of the electricity delivery system. Accordingly, hydrogen energy storage at a utility-scale offers the potential for increasing the levels of variable renewable energy that can be harnessed by the power producers or systems operators.

Approach

HNEI is using a four-step process to evaluate options to evolve the energy systems:

1. Develop and validate rigorous analytic models for electricity and transportation.
2. Develop and model scenarios for the deployment of new energy systems including additional renewables.
3. Identify and analyze mitigating technologies (demand side management, storage, Smart Grid, advanced controls, forecasting, future gen) including hydrogen production to address systems integration (grid stability) and institutional issues.
4. Conduct testing and evaluation to validate potential solutions to facilitate utility acceptance.

Under separate DOE and industry-funded efforts, HNEI has been conducting energy roadmapping and technology validation to identify economically viable technologies to transform island energy infrastructures. HNEI's subcontractor, General Electric (GE), developed two models of the Big Island grid utilizing GE's proprietary modeling technology. Transient performance was modeled using the GE Power Systems Load Flow software model:

- Full network model incorporating generator governors and automated generation control.
- Transient stability simulation looking at challenging times with fluctuating renewables to check transient stabilities.
- Long-term dynamic simulation.

A production cost model was developed using the GE Multi Area Production Simulation software model:

- Representation of dispatch and unit commitment rules.
- Hour-by-hour simulation of grid operations for a full year, taking into account ramp rates and dispatch rules; for example, minimum percentage load for baseload units.
- Model outputs include cumulative fuel usage, emissions, and variable cost.

Frequency variability due to wind fluctuation of the Big Island grid was used as the initial test of the model. The Big Island grid has the following characteristics:

- 100 to 200 MW with early evening peak
- 30 MW wind
- 30 MW unregulated geothermal
- Significant and growing photovoltaics

To explore the potential of the hydrogen energy storage opportunity, this project will evaluate the value proposition of using utility-scale electrolyzers to both regulate the grid and use excess electricity from renewables to make hydrogen

for various products. In this initial phase of the project, an electrolyzer will be installed at the Puna Geothermal Ventures (PGV) geothermal plant on the Big Island. The electrolyzer will be operated in a dynamic mode designed to validate its ability to be ramped up and down to provide frequency regulation. Data will be collected to analyze the ability of the electrolyzer to ramp up and down, and to determine its durability and performance under these dynamic operating conditions. The hydrogen produced by the system will be used to fuel two hydrogen-fueled buses to be operated by the County of Hawaii bus company.

Future Directions

- The project is underway but equipment and infrastructure need to be installed and operated before any results can be evaluated.
- Future work involves the procurement, installation, and operation of the following:
 - Installing hydrogen production systems and infrastructure at the PGV geothermal site.
 - Installing hydrogen dispensing systems and infrastructure at the County of Hawaii Mass Transit Agency bus depot site in Hilo.
 - Procuring and operating two Ford E-450 shuttle buses.
 - Operating the electrolyzer and hydrogen systems at the PGV and County of Hawaii Mass Transit Agency sites.
 - Collecting and analyzing system performance data.
 - Preparing performance reports and sharing it with project sponsors and industry.
- If results show positive results, apply for a phase 2 follow-on project that increases the size of the electrolyzers.

Project Start Date: May, 2010
Project End Date: September, 2013

cells at up to 10 partner locations centered primarily in California and Oregon.

- The PNNL team conducted site visits and telephone calls with many FCS manufacturers to gain insight from manufacturers prior to generating the request for proposal (RFP).
- We established an open dialog with manufacturers regarding overall requirements for the RFP through the Fuel Cell and Hydrogen Energy Association.
- PNNL finalized Technical Requirements and Evaluation Criteria documents in which the technical proposal was worth 60 percent of the points, and the cost proposal was worth 40 percent of the points.
- The RFP was released in December, and proposals were due in early February.
- We established models of FCS cost and technical performance which was part of the technical proposal submittal.
- Decision to negotiate award ClearEdge Power from Portland, Oregon in March.
- PNNL and ClearEdge signed a contract in late May, 2011.

Fiscal Year (FY) 2011 Objectives

The overall objective of this project is:

- To demonstrate combined heat and power fuel cell (CHPFC) systems in small commercial facilities.
- Assess the system performance of the demonstration systems.
- Document market viability of this class of fuel cells for small commercial facilities.

This objective is being accomplished by working with commercial fuel cell manufacturers and their partners to manufacture and install CHPFC systems for application and demonstration at several small industrial facilities.

Technical Barriers

This project aims to address technical and economic issues preventing the full commercialization of fuel cell systems (FCSs). This includes:

- Lack of long-term validated performance data for 5 kilowatt electric (kWe) to 100 kWe FCS
- Energy performance
- Durability
- Reliability
- Installation, operations, and maintenance costs

FY 2011 Accomplishments

We established baseline technical performance models, down-selected the most competitive projects and issued a final contract with ClearEdge Power to provide up to 38 fuel

Introduction

Research and development progress has paved the way for fuel cells to enter the commercial market in applications including stationary power generation and propulsion for vehicles. Accelerating fuel cell use in these key early markets will create jobs in an industry that needs high volume purchases to ramp up production, decrease costs, support commercialization, and enable a domestic supplier base. Early markets will also greatly expand the growth of green jobs with new opportunities associated with manufacturing fuel cells and related hydrogen technologies, fuel cell maintenance and support systems, and hydrogen production, delivery, and storage. In addition, the success of these early markets will help the fuel cell industry overcome a number of non-technical barriers that also face the broader marketplace, including the lack of practical user operating experience, the lack of user confidence, and the inherent resistance to new technologies.

As stated above, the objective of this project is to demonstrate CHPFC systems in small commercial facilities and assess their performance to help determine and document market viability. This information is important for the DOE, the fuel cell community, and most importantly for small commercial facilities that have power and heat requirements for their operations. PNNL is working with commercial fuel cell manufacturers and their partners to

manufacture and install CHPFC systems for application and demonstration at several small industrial facilities. It is also our objective to work with the fuel cell manufacturers and industrial partners to obtain performance data on these systems over the course of several years. The information that is gathered, analyzed, and documented during these demonstrations will be used to benefit and bolster the domestic supply base, increase user confidence, compete in the market place in terms of value provided, and provide favorable reduced lifecycle cost, energy, and emission savings compared to incumbent technologies (e.g., lead acid batteries, combustion engines, or power/heat generators) without tax incentives and with a reasonable chance of approaching parity through short-term technology or mass production improvements. In addition, it is expected that we will gather and analyze “real-world” data from units “in the customer’s hands” to validate performance, durability and reliability; installation, operations, and maintenance costs; and identify remaining barriers to widespread commercialization.

Approach

Our approach to the deployment of CHPFCs at small industrial locations was based upon the notion that the manufacturers of fuel cells know their customers and would propose deployments at locations that would meet the requirements set forth by PNNL. In addition, our approach is to have PNNL monitor and analyze the performance data resulting in the development.

First, we established a baseline model input for cost and technical performance of the fuel cell systems in order to have a common basis in which to evaluate the systems that will eventually be deployed. Several key data packages were included in the input that was categorized into three areas:

- Engineering performance of the installed systems.
- Financial performance of the FCSs including FCS cost, and the breakdown of cost elements.
- Environmental performance of each deployment including feedstock energy source, greenhouse gas emissions, other pollutants, and end-of-life plans (recycle).

Next we set out to acquire the fuel cell systems for demonstration. The acquisition process was conducted through an open competition in which both U.S. and foreign companies were solicited for proposals. While foreign competition was encouraged, all of the deployments were required to occur in the U.S. We required that the manufacturers and the end-user demonstration sites would team together for this acquisition. As such, the industrial team would serve as the integrator for each demonstration. Also, as part of the procurement process, we required a minimum 50% cost share from the fuel cell manufacturer and end-user team for each deployment.

After the fuel cell manufacturers and their industrial partners were selected, the fuel cells would be deployed at each of the end-user industrial sites. At that point, we will initiate the continuous monitoring key parameters of the systems. Key parameters that we are planning on remotely monitoring include:

- Instantaneous and cumulative power generation.
- Grid voltage at the inverter.
- Power that is utilized by the facility as well as power that is exported to the grid.
- Internal cabinet temperatures.
- Heating and cooling temperatures of water as well as the flow rates.
- Heat exchanger cooling fan speeds.
- Exhaust temperature.
- Fuel inlet flow rate and cumulative fuel use.
- Heat generation rate and cumulative heat generated.
- Cumulative system time on load.
- System availability.

The last step in our approach is to analyze and document the performance data collected over at least a two-year period of each fuel cell system deployed. These analyses will include recommendations on the technical performance, economic performance, and the environmental performance. Based upon this information, a case will be presented on the viability of this class of fuel cells for light industrial applications.

Results

At this early point in the project, a contract has been signed with ClearEdge Power in Hillsboro, Oregon to manufacture and deploy fuel cells in Southern California, Northern California, and Oregon. The process of fielding these systems is occurring during the third and fourth quarter of FY 2011, and when the systems are commissioned, data collection and analysis will be initiated. At the time of this report, there are no technical results of real time monitoring available, nor has any analysis been conducted.

Project Start Date: July 30, 2010
Project End Date: Project continuation and
direction determined annually by DOE

Fiscal Year (FY) 2011 Objectives

NREL is fostering the integration of hydrogen and fuel cell technologies into communities to support the goals of energy efficiency, conservation, sustainability, renewable energy and reduced greenhouse gas (GHG) emissions. Our main tasks are to:

- Develop methods and techniques for identifying and evaluating candidate communities for suitable hydrogen and fuel cell technology projects.
- Assist communities in deploying and using hydrogen and fuel cell technologies in innovative integration projects with existing energy efficiency, conservation and renewable energy investments.
- Collect and report performance data, as well as lessons learned, on the hydrogen and fuel cell systems deployed into communities.
- Develop case studies that enable the replication of successful deployments to other similar communities.
- Develop and pursue community education and outreach opportunities for hydrogen and fuel cell systems.
- Build relationships with communities embracing hydrogen and fuel cell technologies. These relations will allow NREL to identify emerging community opportunities for the deployment of hydrogen and fuel cell systems in conjunction with renewable energy and energy efficiency projects.

Technical Barriers

This project addresses the following technical barriers relevant to the published sections of the Fuel Cell Technologies Program Multi-Year Research, Development and Demonstration Plan:

(A) Hydrogen from Renewable Resources

- (B) Hydrogen and Electricity Co-Production
- (C) Expanding Market Opportunities
- (D) Technology Validation
- (E) Education and Outreach

Technical Targets

The Market Transformation Activity does not develop new component technologies or sub-system configurations and, therefore, does not have technology targets. Instead, this subprogram assists in deploying technology systems developed within the other program elements.

FY 2011 Accomplishments

NREL has accomplished the following:

- Developed a decision matrix tool that highlights the most promising community types for hydrogen and fuel cell system deployment projects.
- Ranked 56 community types, using the decision matrix tool developed in this project, against a set of ranking criteria developed by DOE and NREL.
- Executed a Sources Sought effort that resulted in receiving responses from communities proposing to integrate hydrogen and fuel cell systems into their communities.
- Executed a request for proposals (RFP) effort that resulted in receiving formal proposals for community projects that integrate hydrogen and fuel cell systems with existing energy efficiency and renewable energy investments.

Introduction

NREL and DOE are supporting community usage of fuel cell and hydrogen technologies as part of an overall energy efficiency, conservation and renewable energy portfolio. This support includes assisting communities that have existing energy efficiency plans, GHG reduction plans, sustainable energy plans and the like in place to incorporate hydrogen and fuel cell technologies as another option to achieve energy savings and GHG reduction goals. This support also includes identifying opportunities for education and outreach to increase the public's awareness of hydrogen and fuel cell technologies.

Green communities can be thought of as residential, mixed-use, light commercial, municipal or state sites, as examples, that have made a documented commitment to mitigating their environmental impact (reducing their carbon footprint, increasing their energy efficiency,

decreasing their resource consumption rate, and installing renewable energy). This effort will help communities accomplish innovative projects that integrate hydrogen and fuel cell technologies with other complementary energy efficiency, conservation and renewable energy investments. DOE's Energy Efficiency and Conservation Block Grant (EECBG) Program included \$3.2 billion in 2009 Recovery Act federal funds to deploy the least expensive, cleanest, and most reliable energy technologies available—energy efficiency and conservation—across the country. The goals of this investment were to: reduce fossil fuel emissions; reduce the total energy use of the eligible entities; improve energy efficiency in the transportation, building and other appropriate sectors; and create and retain jobs. This project complements this example investment and seeks to leverage the energy efficiency, conservation and renewable energy investments already made (by the EECBG program and others) in communities by identifying communities and potential projects for integrating hydrogen and fuel cell technologies into a community's existing energy efficiency and conservation plan. Integrating hydrogen and fuel cell technologies with energy efficiency, conservation and renewable energy technologies will contribute energy savings and environmental benefits to the community.

Approach

NREL applied the decision matrix tool developed in this project to assess the technical, environmental, economic and social benefits of integrating hydrogen and fuel cell systems into a community. NREL used a systems level approach to understand the project value to the community, as well as the potential for enabling the use of renewable energy. NREL used the following criteria in identifying and selecting candidate communities and deployment projects: innovation of project concept (40%), technical approach (35%) and ability to execute the project (25%).

Results

In order to assess the ability of the candidate community to successfully integrate hydrogen and fuel cell systems into its existing infrastructure, the decision matrix tool evaluates the community in 18 ranking criteria grouped into four categories. The four categories are: 1) technical considerations, 2) market potential, 3) project financials, and 4) opportunities for public outreach and learning. Critical elements for a successful community deployment of a hydrogen or fuel cell system include:

- Community adoption of plans and strategies for GHG reduction, energy efficiency, conservation, clean energy and renewable energy.
- Ability to articulate a hydrogen or fuel cell project that leverages and integrates the existing energy efficiency, conservation and renewable energy investments in the community.

- Ability to describe the value and benefit of a project to the community.
- Knowledge of and connections with the proposed hydrogen and fuel cell technology.
- Ability to conduct high profile public outreach and education activities that increase the public's awareness of hydrogen and fuel cell technologies.

Based on this initial analysis, five community types were identified as high potential deployment sites for hydrogen and fuel cell systems. The community types cited here are example profiles. Once subcontracts are executed with the actual communities identified through the Sources Sought and RFP processes, NREL will collect and analyze the resulting deployment data to build case studies and validate the predictive nature of the decision matrix tool.

Community 1: An off-grid community has just completed extensive energy efficiency, time of use and conservation studies followed by an implementation program that has resulted in a 40% reduction in energy consumption by the community. Now the community has adopted a plan to generate 80% of its remaining energy needs from clean energy sources. The analysis conducted to baseline the community's energy usage profile has also identified opportunities for leveraging clean energy sources available in the community. The analysis indicates that biogas from an anaerobic digester located in the community could be used to operate a fuel cell system that generates electrical power and high quality heat needed by the community. The low quality heat and exhaust gas (rich in carbon dioxide and moisture) from the fuel cell system could also be integrated with a community greenhouse used to produce fresh vegetables for this off-grid community throughout the year. The value of this project to the community is measured in terms of contributing to the community's clean energy plan, reducing GHG emissions and increasing local food production with a decreased carbon footprint.

Community 2: A technology campus has an environmental mandate to improve energy efficiency and reduce GHG emissions by 50%. Retrofitting the existing buildings with energy saving measures has resulted in a 30% reduction in energy consumption; however, more improvements are still required to satisfy the mandate. Additionally, this environmental mandate must be balanced with the business mission of the community, which requires continuous, reliable, high quality power. A proposed fuel cell system could provide continuous back-up power to critical business operations and protect this community from power grid failures that would result in economic losses. Additionally, analysis shows that the fuel cell system would contribute to satisfying the community's base electrical load requirements during normal power grid operation with improved energy efficiency and decreased GHG emissions relative to the grid supplied power. The value of this project to the community is measured in terms of increased

power security for the community's business mission, and contributing to the community's mandate for improved energy efficiency and reduced GHG emissions.

Community 3: A group of mixed-use buildings in an urban setting has banded together to form a community and implemented a district heating and cooling network based on an advanced hydronic loop system. This community has reduced their overall thermal energy requirements by 30% and reduced GHG emissions by 20% relative to their previous levels by implementing this technology. However, the community still has thermal and electrical energy needs that are not being met by on-site generators, and the community's sustainable energy plan calls for installing on-site generators that operate with greater energy efficiency and lower GHG emissions than power delivered via the grid from a coal-fired power plant. Analysis (supported in part by a DOE technical assistance program) indicates that a fuel cell cogeneration plant could provide sufficient electric power and heat to meet the community's requirements. The value of this project to the community is measured in terms of achieving energy efficiency and GHG emission goals adopted in the community's sustainable energy plan.

Community 4: A municipality has defined a plan for becoming a zero net energy community. The municipality has already leveraged federal funds and private foundation grants to greatly reduce community needs for vehicles, thermal and electrical energy. Renewable energy investments in the municipality are not capable of reliably meeting all of the community's energy requirements during peak consumption periods, even with the reduced demands resulting from the existing energy efficiency and conservation investments. The municipality has analyzed its energy consumption profile and identified a system capable of integrating with the existing renewable energy generators to produce hydrogen from renewable sources for use as an energy storage media. The community's plan for achieving net zero energy status includes the acquisition of a fleet of fuel cell-powered buses in the near future. In order to accommodate this future hydrogen demand, the system will be sized to produce sufficient hydrogen to fuel these buses. The value of this project to the community is measured in terms of achieving its goal of becoming a zero net energy community and reducing GHG/air emissions.

Community 5: A community with excess renewable energy production is forced to curtail production when the grid is saturated. Installation of an electrolyzer in the community would allow them to store and sell excess renewable energy production in the form of renewably produced hydrogen. The electrolyzer would generate a new revenue stream for the community by selling the excess hydrogen as fuel to a distribution warehouse located in the community with a fleet of fuel cell-powered material handling equipment. The value proposition for the community is justified by more fully utilizing existing renewable energy investments to shorten the financial payback period on these investments, and increasing revenue for the community. The use of renewable hydrogen

by a local employer increases public awareness of hydrogen and fuel cell technologies, as well as providing a unique and valuable marketing tool for a business located within the community.

Analyzing the responses to the Sources Sought notice revealed the trends shown graphically in Figures 1 and 2. Figure 1 shows that slightly less than half (45%) of the responses were submitted by teams led by traditional communities (e.g. cities, municipalities, counties). Interestingly, this indicates some community awareness of hydrogen and fuel cell systems, and a willingness by community members to take ownership of these systems in their communities. The remaining responses (55%) were led by non-community entities. These non-community led responses were typically championed by commercial entities motivated by the opportunity for the sale of commercial product.

Figure 2 shows the breakdown of technology types proposed in the Sources Sought responses. Some of the responses incorporated multiple technologies, so each of the proposed technologies was accounted for separately in this analysis. The most common type of proposed technology in the Sources Sought responses was a stationary fuel cell for

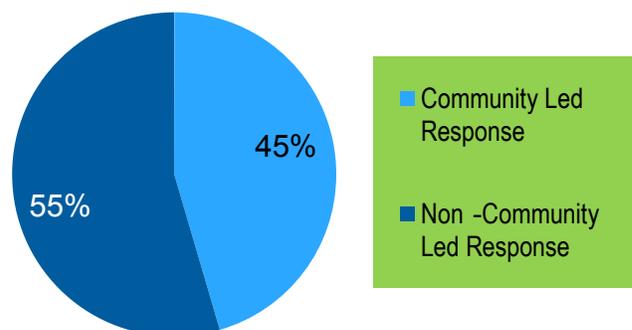

FIGURE 1. Of the Sources Sought responses received, 45% were community led responses while 55% were non-community led responses.

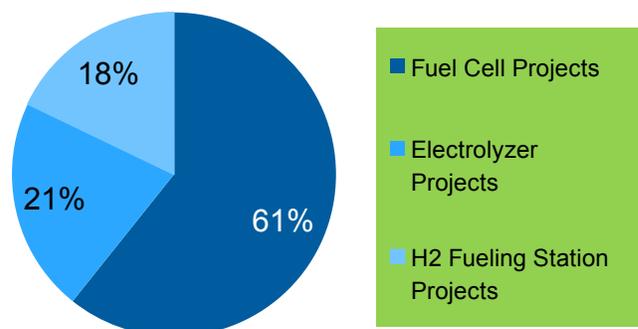

FIGURE 2. The breakdown of technology types proposed in the Sources Sought responses. Fuel cell projects were identified in 61% of the responses, followed by electrolyzer projects in 21% of the responses and hydrogen fueling station projects in 18% of the responses.

generation of electricity and heat, which was identified in 61% of the responses. The second most common proposed technology was an electrolyzer for splitting water into hydrogen and oxygen gases, typically utilizing electricity from a renewable energy source such as wind or solar. The third most common technology found in the Sources Sought responses was a hydrogen fueling station for dispensing hydrogen for transportation applications.

Future Direction

- Complete subcontract negotiations which will result in NREL awarding subcontracts to communities to assist them in achieving innovative integrations of hydrogen and fuel cell systems.
- Monitor the awarded subcontracts.
- Analyze operational data collected by the subcontracted communities. This analysis will include hydrogen and fuel cell system performance data, and will quantify how the project helped the community in progressing towards its sustainability and conservation goals.
- Build case studies from the successful deployment projects that will serve as precedence for similar communities to execute their own hydrogen and fuel cell projects.

Project Start Date: June 1, 2010
Project End Date: December 30, 2012

- Initial testing shows that DMFC systems used in Class III pallet jacks achieve 14 hours of operation on a single methanol fueling, compared to an average of less than 7 hours of autonomy for traditional battery-powered lifts.

Introduction

The National Renewable Energy Laboratory (NREL) and the U.S. Department of Energy (DOE) are interested in supporting the development of early market applications for fuel cell technologies. A study by Battelle Memorial Institute, "Identification and Characterization of Near-term Direct Hydrogen Proton Exchange Membrane Fuel Cell Markets," showed that fuel cells have the potential to power material handling equipment (also known generically as forklifts) at a lower overall cost than lead-acid batteries for certain types of operations [1]. Battery-powered forklifts typically use lead-acid batteries that can only provide enough power for one 8-hour shift. Multi-shift operations, therefore, generally require additional battery packs and battery change-outs, which reduces productivity and increases costs of operation.

DOE is currently demonstrating the potential benefits for hydrogen-fueled polymer electrolyte membrane (PEM) fuel cell-powered forklifts compared to 100% battery-powered forklifts. As a supplement to the hydrogen-fueled PEM fuel cell-powered forklift deployment testing, NREL is investigating the use of DMFC technologies in material handling applications. DMFCs, which use a liquid methanol fuel, hold promise to deliver many of the same operational benefits of hydrogen-powered fuel cell MHE, including long run times, short fueling times, and increased productivity. Liquid alcohol fuels such as methanol offer reduced infrastructure costs, high energy density, and low overall fueling costs. (See Table 1 for an overview of the benefits of using DMFCs in material handling applications.)

Fiscal Year (FY) 2011 Objectives

- Deploy and test fuel cell-powered material handling equipment (MHE) using renewable liquid fuels (in particular, methanol).
- Compile operational data of direct methanol fuel cells (DMFCs) and validate their performance under real-world operating conditions.
- Provide an independent technology assessment that focuses on DMFC system performance, operation, and safety.
- Evaluate the business case and market viability of using DMFC technologies in material handling applications.
- In the longer term, help transform the market for the use of fuel cells in material handling applications.

Barriers

This project addresses non-technical issues that prevent full commercialization of fuel cells.

Technical Targets

No specific technical targets have been set.

FY 2011 Accomplishments

- Seventy-five DMFC systems were built, tested, and delivered to customer warehouse sites for real-world use and testing in Class III MHE (as of June 2011).
- DMFC systems underwent initial, beginning of life testing that will be used to provide a performance benchmark for the DMFC systems.

TABLE 1. Benefits of DMFC Power for MHE Compared to Batteries

Expected DMFC Benefits Over Battery MHE	
Longer run times between fueling/charging	Estimated 12-14 hours of autonomy on one fill.
Increased battery and lift reliability	Maintaining state-of-charge and eliminating deep discharge of batteries should extend battery life.
Increased productivity	Reduced need for fills (versus charging) and reduced time for fills (versus charging).
Lower greenhouse gas emissions	Compared to charging batteries using a typical electricity grid mix.
Low-cost infrastructure	Liquid alcohol fuels such as methanol offer low storage and dispensing costs.
Low cost of ownership	Productivity, reliability, and battery life gains expected to enable lower overall cost.

Approach

NREL has partnered with Oorja Protonics on a two-year project to demonstrate and evaluate DMFCs to provide power for MHE in four commercial wholesale distribution centers. In total, 75 DMFC-powered Class III pallet jacks have been deployed in warehouses operated by Unified Grocers, Testa Produce, and Earp Distribution. DMFC lifts are being operated two shifts per day for 15 months, with 5,000 total operational hours expected on each unit. The demonstration includes the use of renewable, bio-derived methanol to characterize the impact on DMFC systems of using renewable methanol fuel.

As part of the project, Oorja built, tested, and deployed pallet jacks using its OorjaPac Model 3 DMFC power pack, which delivers an output power of approximately 1.5 kW and includes a 12-liter methanol storage tank expected to provide 12-14 hours of autonomy between fuelings. Methanol fuel is being dispensed to the DMFC MHE using the OorjaRig methanol dispenser, which is designed to meet all relevant fire and safety codes for indoor methanol dispensing. Oorja is collecting data on both the DMFC systems and the supporting methanol fueling infrastructure. NREL is compiling and analyzing these data and is providing a third-party assessment on the performance of DMFCs used in material handling applications.

Results

Until recently, the primary target use for DMFCs has been for portable power applications, particularly micropower applications. In FY 2011, NREL investigated companies developing DMFC systems that produced output power above 1 kW and were capable of powering Class III MHE. Based on this, NREL released a competitive request for proposals to demonstrate DMFCs to power MHE in commercial warehouse operations. In early 2011, NREL awarded a subcontract to Oorja Protonics to build, test, and deploy 75 DMFC-powered Class III pallet jacks in four commercial food warehousing and distribution centers.

The OorjaPac Model 3 DMFC power packs that are used in this deployment project act in concert with traditional MHE battery systems. Unlike traditional battery systems that have limited run time and require frequent battery changes and charging from the electricity grid, the OorjaPac DMFC system acts as an onboard battery charger, maintaining the battery pack state-of-charge and eliminating electric grid-based battery charging. Figure 1 shows the OorjaPac DMFC system, on its own (left), and integrated with a Class III pallet jack and its battery (right). Initial testing of these DMFC systems show that the OorjaPac needs to be fueled with methanol (with fills expected to take 1-2 minutes) after 14 hours of operation, compared to average run times of less than seven hours for traditional battery systems (see Figure 2). Initial testing using data loggers on operating pallet jacks showed the OorjaPac DMFC system maintained

Photo courtesy of Oorja Protonics

FIGURE 1. The OorjaPac Model 3 DMFC System

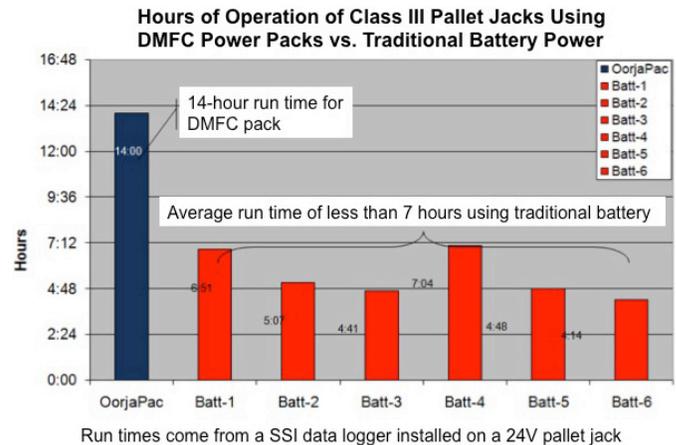

FIGURE 2. Run Time for DMFC Class III MHE Compared to Battery-Powered MHE

a more consistent state-of-charge on the battery packs and avoided deep discharges of the batteries.

The specific configuration of the OorjaPac DMFC system was built to meet customer performance needs. To accomplish this, Oorja performed testing using data loggers of MHE at all four customer sites under this deployment project to benchmark the necessary performance. This information was used to determine the specific fuel cell count in the OorjaPac as well as the hybridization algorithms needed to provide sufficient performance and run times to meet customer needs. Based on this benchmark testing, Oorja built DMFC systems for use at all four demonstration sites. Prototype systems were tested on target customer Class III pallet jacks to ensure proper electrical and mechanical linkage, as well as proper safety, ergonomics, and counterbalance.

Individual DMFC systems underwent performance, reliability, and emissions testing. Beginning of life performance testing of the OorjaPac DMFC systems showed a maximum power output of 1.65 kW. Emissions testing at the anode and cathode sides of the DMFC pack showed overall carbon dioxide emissions to be well below OSHA limits of 200 ppm. Vibration table testing showed minimal impact on system performance from vibration.

Environmental testing showed that operation in higher temperature environments tended to lower overall system efficiency because of higher parasitic power requirements needed to maintain thermal balance. Improved system controls were developed to avoid any freezing of system components during lower temperature use.

Conclusions and Future Direction

- Seventy-five OorjaPac DMFC systems were built, tested, and delivered to customer warehouse sites for real-world use and testing (as of June 2011).
- DMFC systems underwent beginning of life testing that will be used to provide a performance benchmark for the systems.
- Data from these DMFC systems based on real-world use in providing power to Class III pallet jacks are being collected by Oorja and compiled by NREL.

In the next year, NREL will use real-world operating data to characterize the performance of DMFC systems used in material handling applications, including characterization of:

- Site Operations – hours of DMFC forklift use, amount of methanol dispensed, number of fueling events.

- Infrastructure Performance – average fueling time, average fueling rate, number of safety incidences, maintenance required.
- DMFC Performance – hours of operation between fuelings, hours of operation per gallon of methanol, average battery life, battery state-of-charge.

The analysis of real world data will be used to develop a total cost of ownership estimate of DMFC systems, including any productivity improvements, for comparison to battery MHE.

Contract Number: DE-FG36-08GO18113

Subcontractors:

- ¹Advanced Technology International, Charleston, SC
- Ameresco, Inc., Framingham, MA
- Gas Technology Institute, Des Plaines, IL

Project Start Date: June 17, 2011

Project End Date: October 31, 2011

Technical Targets

- Months 1-3: Financial/business case feasibility.
- Months 4-10: Technical feasibility of producing fuel cell-quality hydrogen from LFG source.
- Months 11-17: Validate impact of LFG-derived hydrogen on fuel cell durability and compare it with fuel cell performance using hydrogen supplied by an industrial gas provider.

Approach

With the support of federal, state and private sponsors and stakeholders, the project will be conducted in three distinct phases:

- First, the project team would determine whether a viable business case exists that would permit recovering methane from the existing LFG source, converting it to hydrogen at large scale through an optimized capital equipment investment, and providing that hydrogen via a long term fee-for-services to the host site as the fueling source for its entire fleet of MHE.
- Should such a business case exist, the project next would validate the technical feasibility of taking the existing LFG stream that already has been filtered, dried and pre-treated sufficiently for use in gas turbine electrical generator sets, further cleaning and purifying it to remove the remaining trace contaminants, and then recovering the hydrogen using commercially available steam-methane reformer technology.
- As the final phase of this project, the hydrogen produced from the purified LFG source would be compressed, stored, and distributed to a single site within the host site manufacturing facility to permit a “side-by-side” performance evaluation using actual fuel cell-powered MHE. Hydrogen already available on-site from the contracted industrial gas provider would fuel the “control group” of MHE pieces; hydrogen produced from the pilot-scale LFG-to-hydrogen project would fuel the “test group” of MHE pieces. The performance evaluation would gather data for a period of six months from the control and test group fuel cells, and draw conclusions regarding the impact, if any, of the LFG source of hydrogen on fuel cell durability and maintenance requirements.

Fiscal Year (FY) 2011 Objectives

- Validate that a financially viable business case exists for a full-scale deployment of commercially available equipment capable of taking landfill gas (LFG) to hydrogen under the specific BMW operating environment.
- Validate that commercially available clean-up and reformation equipment can convert BMW's LFG to hydrogen at purity levels consistent with fuel cell industry standards.
- Conduct a side-by-side operational verification of fuel cell material handling equipment (MHE) performance and durability between a test group operating on LFG-supplied hydrogen and a control group operating on delivered hydrogen supplied by an industrial gas provider.

Technical Barriers

This project addresses the following technical barriers:

- Integration of individually-proven technologies into an unproven “end-to-end” solution.
- Unknown impact of long-term fuel cell performance when operating on LFG-derived hydrogen.

FY 2011 Accomplishments

Feasibility study (phase 1) began on June 17, 2011. Expected completion date is September 2011.

Future Directions

- “Go/No-Go” decision for proceeding with subsequent phases of the project will be made upon completion of the feasibility study. Based upon information already available to the project team, the likelihood of a finding of financial feasibility is high.
- Once financial feasibility has been confirmed, the project team will begin the technical feasibility portion of the project at pilot-scale (notionally 15 kilograms per day of hydrogen production).

FY 2011 Publications/Presentations

1. Presented project overview at Annual Merit Review (poster session) on May 10, 2011.

X.8 Incorporation of Two Ford H₂ ICE Buses into the Shuttle Bus Fleet

Project Start Date: July 1, 2010

Project End Date: September 30, 2011

FY 2011 Accomplishments

- Worked with LLNL Operations and Business Offices/Facilities and Infrastructure Directorate and its Sandia counterparts to permit mobile H₂ refueling station at LLNL and H₂ bus use at the LLNL/SNL facilities.
- Collaborated with Air Products and Chemicals to bring mobile H₂ refueler to LLNL.
- Instituted refueling training and H₂ bus operation for drivers.
- Worked through insurance issues associated with on-site refueling and public ridership.
- Instituted H₂ shuttle bus service for LLNL and SNL and have executed several community outreach activities.
- Established means to monitor ridership, refueling, and vehicle operations.

Introduction

As part of the “Walk the Talk” initiative within DOE, whereby the use of hydrogen technology in the DOE complex is increased, DOE has asked LLNL and SNL to establish and manage a hydrogen bus (taxi service) project servicing SNL and LLNL in Livermore, California. Ford has made available a number of hydrogen buses (internal combustion engine [ICE], with high pressure storage of hydrogen) that seat 12 people, plus driver (or 7 plus one wheelchair and driver), have a range of 150 miles, and on-board storage of 30 kg of hydrogen at 5,000 psi. These vehicles achieve near-zero regulated emissions (below Super Ultra Low Emission Vehicle regulation for oxides of nitrogen) and no CO₂ emissions. In the past year, SNL and LLNL have partnered to lease two buses (one year lease) for the demonstration project. The buses have been serving the local LLNL/SNL staff community. They directly replaced two diesel buses that were in use, thereby achieving reductions in diesel emissions at the two sites.

The purpose of this project is to demonstrate hydrogen technologies and educate the community. As part of the community outreach goals, we have engaged the broader Tri-Valley area (cities of Livermore, Dublin, Pleasanton, San Ramon) and others on event support using the H₂ buses. We have also initiated educational activities with nearby Las Positas College. We also plan to coordinate with the Livermore community public transportation companies to enhance operations.

Approach

Our approach to this project was as follows. Prior to receiving the buses, extensive discussions were carried

Fiscal Year (FY) 2011 Objectives

- To promote the early market adoption of hydrogen technology.
- To displace diesel-fueled taxi vehicles at LLNL and SNL.
- To help promote public education on the benefits of hydrogen and fuel cell technology.

Technical Barriers

This project addresses the following technical barriers assigned to this project:

- (A) Non-technical issues preventing full commercialization of hydrogen and fuel cell systems.
- (B) Hydrogen storage.
- (C) Lack of hydrogen refueling infrastructure performance and availability data.
- (D) Maintenance and training facilities.

Technical Targets

- Promote the use of hydrogen technology to the public.
- Reduce diesel use at the LLNL and SNL sites.
- Gain extensive experience using H₂ buses by driving daily with high mileage use.

out with LLNL and SNL facilities management, and with the LLNL Site Manager for the Nuclear National Security Administration to secure “buy-in” for the project. With the project receiving strong acceptance and support, we leased the H₂ buses from the Ford Motor Company, followed by an initial certification of them in collaboration with Ford maintenance staff. During this certification phase, we designed appealing “wraps” for the bus to bring attention to their H₂ technology (Figure 1). There are no hydrogen stations currently operating in the Tri-Valley area, so we had to establish a mobile refueling station at the LLNL site using an Air Products Mobile Refueler, shown in Figure 2.

With reliable fueling established, the buses were integrated into the LLNL/Sandia taxi service, replacing two buses that were operated on diesel fuel. Thus, use of the H₂ buses led to a decrease in diesel fuel use at the two laboratories. Furthermore, the H₂ buses were used for educating the local public on the benefits of hydrogen and fuel cell technology. We managed frequent maintenance problems that arose with the buses, these problems being unrelated to the hydrogen technology (except for the need to replace a sensor, with the failure being detected with on-board diagnostics), and many involved traditional bus mechanical systems.

FIGURE 1. Final Design of “Wrap” for Bus

FIGURE 2. Air Products Mobile Refueler Servicing the Two H₂ Buses

Results

In November of 2010, the two H₂ buses were integrated into the LLNL/SNL fleet. The buses travel all over the LLNL and SNL sites, as well as to the local commuter train station, picking up LLNL and SNL employees and transporting them to our campuses. The typical ridership per shuttle bus is ~80-100 passengers/day with each H₂ bus traveling ~80-100 miles each day. The H₂ buses are “topped off” with hydrogen each day with ~13 kg of hydrogen. We have put on 8,757 miles on the buses in approximately six months of operation (up to June 30, 2011). The average number of miles driven by each bus is 730 miles per month. With regard to a fuel comparison, the average number of gallons of diesel used on our previous buses is 168 gallons per month (per bus), so that is our savings. It is our understanding that this level of use is among the highest for DOE facilities using such buses.

Both buses found extensive use in a number of community outreach activities. Two of these are described in a little more detail here. The first community event was a joint SNL/LLNL Celebration of Hydrogen Technology in downtown Livermore on February 22, 2011. This event was organized by the project and LLNL and SNL protocol and public relations personnel. Approximately 70 members of the public, media, local dignitaries and LLNL and SNL management and staff were on hand to see the two H₂ buses, along with the H₂ Fuel Cell Mobile Light, the cryo-compressed hydrogen vehicle from LLNL, and a number of posters on hydrogen research and development being conducted at the labs. Speakers included:

1. Ron Cochrane, Executive Officer from LLNL and Bob Carling, Director of the Transportation Energy Center from SNL.
2. John Garbak, DOE Technology Development Manager
3. John Marchand, Vice Mayor, City of Livermore
4. Alice Williams, Nuclear National Security Administration Site Manager

KPIX television (San Francisco) broadcast video from the celebration on their evening news, and press from two local newspapers attended as well. Representation from Congressmen Garamendi’s and McNerney’s offices and California State Assembly member Joan Buchanan were also in attendance. A picture from the event is shown in Figure 3. The public were given rides on the buses, and had a chance to talk with LLNL and SNL staff scientists about the hydrogen technology depicted in the posters.

In another community outreach event one of the H₂ buses was on display at the Expanding Your Horizons conference on Saturday February 26, 2011 at the Diablo Valley Community College, San Ramon campus, with rides given to attendees. The Expanding Your Horizons conference serves to:

FIGURE 3. Celebration of Hydrogen Technology in Downtown Livermore, February 22, 2011

- Increase the interest of young women in math and science through positive hands-on experience (over 300 present).
- Foster awareness in math- and science-related careers.
- Provide young women with opportunities to meet and interact with positive role models who are active in math- and science-related careers.

A picture of Expanding Your Horizons attendees in the H₂ bus is shown in Figure 4.

Other outreach events include the John Muir Birthday-Earth Day Celebration in Martinez, California on April 16, 2011. This event provided a shuttle service from the parking area to the event main gate. Over 1,000 people attended this event. In addition, lectures were given on hydrogen technology (fuel cells, hydrogen storage, H₂ bus, H₂ mobile light) to an environmental science class at Las Positas Community College in Livermore on April 12, 2011. One of the buses was also used at the SNL “Take Your Sons and Daughters to Work Day” on April 28, 2011. The buses were on display at the Bay Area American Chemical Society meeting in Oakland, California on April 30, 2011. The buses were also highlighted at the LLNL internal safety fair on June 22, 2011. Finally, the buses were on display at the opening of the Innovation for the Green Advanced Transportation Center in Livermore which is located near the laboratories on June 30, 2011. The opening

FIGURE 4. Students attending the the Expanding Your Horizons conference on Saturday February 26, 2011 at the Diablo Valley Community College, San Ramon campus, on-board the H₂ Bus.

was attended by 300 people, including Congressman John Garamendi. At all of these events we handed out brochures that explain the DOE Hydrogen Market Transformation sub-program and information about the buses. We were on hand to answer questions about the buses.

Conclusions and Future Directions

Two Ford H₂ buses were successfully integrated in the LLNL/SNL taxi fleet, and have been extensively used for transporting laboratory staff within the LLNL/SNL campuses, and also to a local commuter rail stop. To our knowledge, the LLNL/SNL buses have received the most use (highest number of miles driven, greatest number of refuelings) of any H₂ bus effort in the DOE program. Use is ongoing at this time. Future activities associated with the H₂ buses, until the end of FY 2011, include:

- Monitoring shuttle bus mileage, ridership, and vehicle operation.
- Maintaining the vehicles in collaboration with Ford.
- Conduct community outreach events.
- Curriculum development with Las Positas College and high school demonstrations.
- Annual Community Festivals/Antique Automobile Shows/farmers markets.

X.9 PEM Fuel Cell Systems for Commercial Airplane Systems Power

E-mail: lekleba@sandia.gov

DOE Manager
HQ: Pete Devlin
Phone: (202) 586-4905
E-mail: Peter.Devlin@ee.doe.gov

Project Start Date: July 1, 2010
Project End Date: March 31, 2011

- **Performance Impact:** Found that, in some scenarios, using an on-board PEM fuel cell system could decrease the amount of jet fuel needed to generate electricity by over 30%. The amount of CO₂ that could be avoided by a fleet of PEM fuel cell-equipped airplanes could be over 20,000 metric tons per year (assuming renewable hydrogen is used to power the fuel cell). However, this benefit is not reachable using current fuel cell and hydrogen storage technology but rather requires DOE-target (2015) technology for both hydrogen storage and PEM fuel cells.
- **Electrical System:** Discovered that the addition of a fuel cell system does not adversely affect the existing electrical system, and in fact can provide a faster transient response than current aircraft generators that operate off of engine shaft power.

Fiscal Year (FY) 2011 Objectives

- Determine feasibility of implementing a proton exchange membrane (PEM) fuel cell on-board a commercial airplane.
- Quantify the performance benefit (or penalty) of such a fuel cell system.
- Understand the impact of the fuel cell on the existing electrical distribution system.

Technical Barriers

This project addresses the following technical barriers:

- (A) System Weight and Volume
- (B) Cost
- (C) Efficiency

Technical Targets

Our project determines the PEM fuel cell applications and configurations that have the lowest volume and mass, and the configurations that lead to the highest energy efficiencies for aircraft use. Cost is addressed indirectly: the results of this project may make it easier for airplane companies to incorporate fuel cells into their designs, thus increasing the quantities of fuel cells manufactured and leading to lower per-unit costs.

FY 2011 Accomplishments

- **Feasibility:** Found that it is technically feasible to install and operate a PEM fuel cell system on-board a commercial airplane.

Introduction

Fuel cells have become increasingly important as alternative sources of power, offering the potential for drastic reduction in emissions in particulate matter (PM), nitrogen oxides (NO_x), and CO₂. In addition, they offer exceptionally quiet operation, highly efficient use of the fuel energy, and a high energy storage density compared to batteries. For a number of years, the manufacturers of commercial aircraft, most notably Boeing and Airbus, have realized that fuel cells may offer advantages for commercial aircraft operation. Apart from the emissions reductions and thermal efficiency referenced above, they can constitute distributed power systems, enabling locating the power near the point of use and also reducing the power draw from the engines.

The real question is if fuel cells offer operational advantages over traditional power in systems that are used routinely in flight, for example galley power, in-flight entertainment, and to provide additional power to the aircraft electrical grid when “peaker” power is needed. This interest in the use of fuel cells is timely, as the electrical needs on-board aircraft are going up considerably. Systems that were formerly hydraulic in operation are now being converted to electric operation [1]. For the new Boeing 787, the aircraft-wide electrical generation capacity is 1.5 MW – almost an order of magnitude larger than previous designs. This study, then, is an initial investigation of the use of PEM fuel cells on-board commercial aircraft. We seek to understand how to physically deploy a fuel cell on an aircraft, the impact of system volume and weight on the airplane, and the impact on jet fuel consumption, both in relation to fuel currently devoted to electricity generation, and the overall fuel needed by the airplane to fly a given mission.

Approach

To accomplish this analysis, two basic airplane designs were considered: one airplane without a fuel cell (the base airplane), and one airplane designed to perform the same mission as the first airplane, only carrying a fuel cell and associated hardware to fulfill a specific electrical need. The difference in the performance of these two airplanes is made quantitative by calculating the fuel required to fly the mission in the two cases, which requires understanding the influence of weight, volume, and thermal issues on the airplane drag. Calculating the required fuel also allows us to assess fuel use as it directly relates to power generation on the airplane. The key point here is that we assess not only the benefit of the fuel cell on generating electricity, but also the penalty the fuel cell system places on the airplane's performance due to its added weight and possibly drag issues that arise from handling fuel cell thermal issues. Combining these two is necessary to determine the overall effect of the fuel cell system.

We performed the analysis by designing and examining several system options using realistic assumptions about performance and size of the various components. After assessment of the available state of the art in commercially available PEM fuel cells, the Hydrogenics HyPM 12 PEM fuel cell was chosen as a unit representative of the industry. For hydrogen storage, several options were considered: 350 bar compressed gas, 700 bar compressed gas, metal hydrides, and liquid hydrogen storage, in both conventional cryogenic storage and "cryo-compressed" storage. For storing hydrogen for the PEM aviation fuel cell, we selected 350 bar compressed gas tank technology due to its combination of high specific energy and current availability. Other equipment such as heat exchangers, blowers, and pumps were all selected based on commercially available units with the specifications appropriate for the system. For the electrical components, a ± 270 volt direct current distribution system provided the lowest system weight, although the increase in weight due to a 230 volt alternating current system was less than 50 kg (110 lb). Both of these options provide the advantage of direct interface with the existing electrical system on the 787.

Results

After consideration of factors such as safety, available space, maintenance, and wiring and tubing/piping lengths, we chose to locate the fuel cell system in the airplane's fairing area (where the wings join the fuselage), although locating the system in the tail cone would not change the results by much. Locating the fuel cell system next to the load it serves could save up to 150 kg (331 lb) of mass and provide some redundancy benefits, but this was avoided because of the concern with occupying space that is currently used for other purposes.

The amount and method of recovering the heat rejected from the fuel cell (waste heat recovery) was found to be a

critical factor in determining the performance benefit of the fuel cell system. To this end, eleven different waste heat recovery options were examined thermodynamically. We found that a system that uses the heat from the fuel cell to pre-heat the jet fuel carried by the airplane will provide the largest overall performance benefit. This method of heat recovery is already used in commercial airplanes within the engine compartment, where the lubrication oil is cooled by jet fuel, and it is more ubiquitous in military aircraft where the fuel is used to cool many of the military airplane's systems.

We considered the integration of the fuel cell system with the airplane's electrical system, for it is necessary to ensure that the addition of the fuel cell system does not disrupt the electrical system or cause instabilities. Through dynamic simulation we found that the fuel cell system performed satisfactorily whether connected to the airplane's system or as a stand-alone system. In fact, our results indicate that the integration of the fuel cell system with the existing electrical system may provide a faster response to load changes than the current configuration.

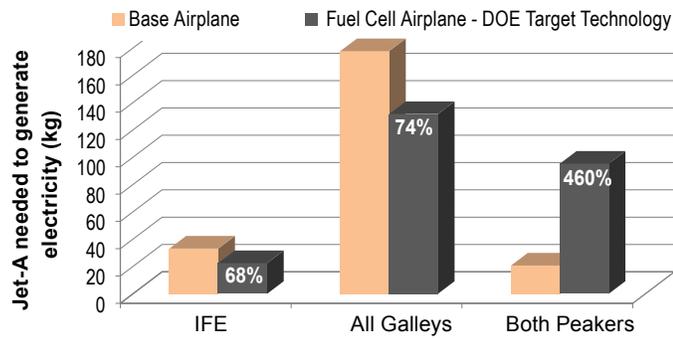

Conclusions and Future Directions

In the end, we found that while adding a fuel cell system using today's technology for the PEM fuel cell and hydrogen storage is technically feasible, it will not give the airplane a performance benefit no matter which configuration was chosen (although there may be other benefits that make it worthwhile from the airplane manufacturer's or airline's point of view). However, when we repeated the analysis using DOE-target technology for the PEM fuel cell and hydrogen storage, we found that the fuel cell system would provide a performance benefit to the airplane (i.e., it can save the airplane some fuel), depending on the way it is configured. This analysis also showed that the DOE-target technology fuel cell system could generate electricity using over 30% less fuel than the current airplane, even considering the penalties due to the fuel cell system's weight and drag (Figure 1). If a fleet of 1,000 airplanes were equipped with such systems, it could save over 20,000 metric tons of CO₂ annually (Figure 2).

This project is complete. It is recommended that subsequent work on this topic focus on detailed design and testing of an actual aviation PEM fuel cell system, including both mechanical and electrical aspects.

Project Start Date: July 19, 2010
Project End Date: September 30, 2011

Introduction

This study examines electrical power generation for commercial aircraft using SOFC technology. The focus of this study is “more-electric” airplanes with the Boeing 787 used as a case study. More-electric airplanes minimize extraction of bleed air from the engine compressor stages and instead run electrical generators driven by the engines to satisfy loads. More-electric airplanes have higher electrical generation rates and thus stand to show greater benefit from an increase in the efficiency of electrical generation.

SOFC technology can generate electrical power at higher efficiency than is achieved by using power from the main engine shaft to run a generator. Hence, unlike the existing auxiliary power unit (APU), which is turned off once the main engines are started, a fuel cell power unit would operate throughout the flight to maximize fuel savings. Fuel cell power units are expected to be somewhat heavier than turbine APUs resulting in a heavier aircraft. For an SOFC power unit to be feasible, the fuel savings for electrical generation must exceed the increase in fuel consumption due to weight.

Fiscal Year (FY) 2011 Objectives

- Examine electrical power generation for commercial aircraft using solid oxide fuel (SOFC) technology.
- Determine amount of weight reduction required to make SOFC power systems net fuel efficient on aircraft.

Technical Barriers

Identify and quantify barriers to deployment of fuel cell power systems on commercial aircraft.

FY 2011 Accomplishments

- Obtained extensive information from Boeing on the 787 electrical system, including generation and distribution systems, load profiles and fuel consumption.
- Conceived electrical system using an SOFC on a direct current (DC) bus that will save ~100 kW in power conversion losses and almost 270 kg in conversion equipment.
- Modeled a matrix of SOFC power systems to determine anticipated fuel efficiencies. Most promising system uses steam reforming, anode recycle and compressor/expander.
- Determined breakeven weight change vs. flight distance for various SOFC system efficiencies: a system with 70% conversion efficiency can add up to 4,600 kg and still break even on fuel consumed.
- Generated estimates of system weights (not yet complete) for SOFC system with steam reformer, anode recycle and compressor/expander.

Approach

System flowsheets were analyzed to estimate weight and efficiency. Mass and energy balance was modeled using ChemCAD software coupled with a PNNL stack performance model of a planar anode-supported SOFC. The stack performance model is calibrated to actual data for a promising new materials set that yields about 75% higher power density than previous cells. Based on input values for pressure, inlet temperature, flow rates, compositions, and cell voltage, the SOFC model predicts the power density achieved. All systems modeled were assumed to operate using desulfurized jet fuel that is loaded into a dedicated tank. Approaches to the flowsheet included auto-thermal reforming, steam reforming and anode recycle steam reforming. All systems included a compressor/expander to compress air drawn in from the atmosphere and then expand the exhaust gases to recover work. System pressures were examined at 0.835 atm (cruise cabin pressure), 3 atm and 8 atm. Operating cell voltages of 0.70, 0.75, 0.80 and 0.85 V were analyzed.

A revised 787 electrical distribution system was considered to take advantage of the SOFC power being generated as DC rather than alternating current (AC) power. An estimate of the electrical power required was developed based on an understanding of the Boeing 787 loads. The impact of the addition of the SOFC APU weight on main engine fuel consumption was determined using a PianoX (<http://www.lissys.demon.co.uk/index2.html>)

model of the 787-8. Flight profiles for trips of 1,000, 3,000, 5,000 and 7,000 nautical miles were calculated for a range of payloads. The PianoX model was allowed to select appropriate parameters for each flight such as rate of climb, initial cruise altitude, rate of descent, etc., and provided fuel consumption data as a function of payload. A breakeven weight for the APU was calculated by determining the point at which the fuel saved during the flight due to the efficiency of the SOFC would be offset by the increase in main engine fuel consumption required to carry the additional APU weight. Estimates of APU weight were compared to the breakeven weight.

Results

Key factors in the comparison of SOFC power system weights to break even values include:

Modification of Power Distribution - For the SOFC-based electrical system, the aircraft distribution system was modified so that the SOFC directly produces the +/-270 VDC power used for major loads. The existing 230 VAC loads are moved to +/-270 VDC bus and 80% efficient DC/DC and DC/AC power conversions are used to provide power to 115 VAC and 28 VDC loads. This approach reduces the conversion losses, reducing the required gross power generation from 918 kW to 821 kW. The weight saved in power conversion equipment is estimated to be 268 kg.

Elimination of Turbine APU - It is expected that the SOFC power system would be divided into multiple independent units to provide redundancy. In this configuration, the turbine APU could be eliminated, saving 245 kg. The ram air turbine was assumed to still be present. Engine generators cannot be eliminated since they double as starters for the main engines.

SOFC System Configuration - The extent of fuel savings depends on the flowsheet for the SOFC system. Key system features include the air compression/expansion, the fuel cell itself and the approach to reforming the fuel.

Air Compression - In all cases, ram air is compressed to SOFC pressure in a compressor (80% efficient) and exhaust gases expanded through a turbine (85% efficient) to ambient to recover mechanical energy. Weight and performance of the compressor/expander was based on a Williams WR2 jet engine. Adjustments were made to scale the estimated weight based on the air flow and compression ratio required for each flowsheet. Shaft power is balanced by either using electrical power as input or generating AC power and converting it to +/-270 VDC. Cabin air is not used as input to the compressor to avoid concern over upsetting normal cabin venting.

Fuel Cell - The fuel cell is based on a Delphi Gen 4 stack with a new material set which is capable of higher power density than the more established materials currently used. The new materials set has been tested in small button cells, but has not yet been scaled up. The weight of

the stack was taken to be 62 kg for a 100-cell stack. This weight represents the current weight of a 100-cell Gen 4 stack design minus a relatively heavy base plate and frame (33.5 kg). It is believed that a much lighter weight solution to the base plate and frame can be developed. The power density in the stack is a function of anode gas composition, fuel utilization, excess air, operating pressure and voltage. Stack electrical conversion efficiency is purely a function of stack voltage.

Reforming Approach - Autothermal reforming, single anode pass steam reforming and anode recycle steam reforming flowsheets were modeled. Figure 1 shows the logical layout of the anode recycle flowsheet. Figure 2 shows that the anode recycle steam reforming provided significantly higher system efficiency than other approaches. In this approach all steam required for reforming is generated on the SOFC anode and waste heat from the fuel cell is used to drive the endothermic steam reforming reaction. Net power from the compressor-expander provided only a small contribution (3.2% to 4.7% at 3 atm) to total net power output. Since the SOFC offers higher efficiency than a turbine, efficiency is improved with more power from the SOFC and less from the turbine as long as electrical power is not required as input to drive the compressor. Also, the decision to configure the system to directly generate DC power penalizes the turbine for losses in AC/DC conversion.

Weight Estimates - The system was assumed to be placed in a titanium vessel designed for a safety factor of 1.5 on yield stress. The heat exchangers, anode blower and

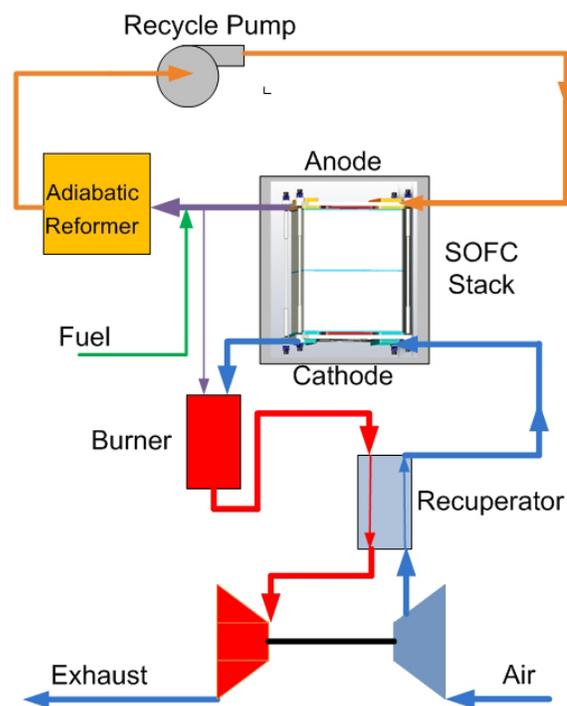

FIGURE 1. Logical Flowchart for Anode Recycle Steam Reforming Flowsheet

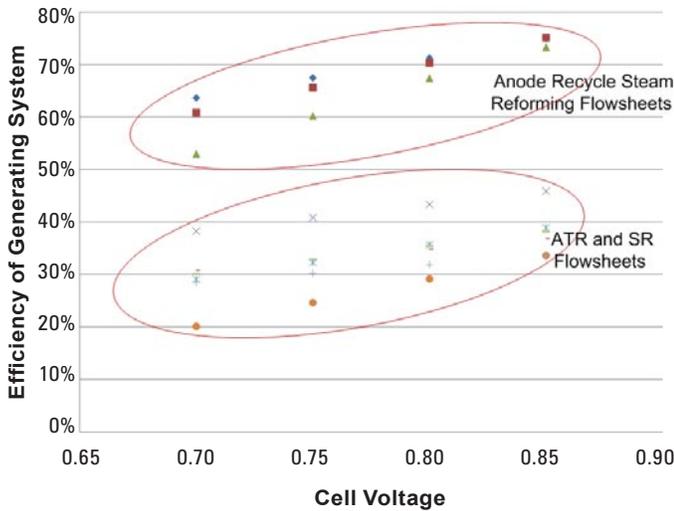

FIGURE 2. Efficiency as a Function of Cell Voltage Flowsheet Configuration

reformer were scaled based on an existing SOFC power system operating at 6.3 kW. Stacks were estimated at 62 kg/100 cells. Current weight estimates do not account for the insulation, connecting pipes, support structure, instrumentation and controls. Table 1 shows a summary of the estimated net efficiency and weight for analyzed anode recycle cases. Highlighted cells indicate the most attractive regions for operation.

TABLE 1. Net Efficiency and Weight Added by SOFC Power Unit (kg)

Pressure	SOFC Cell Voltage			
	0.85	0.80	0.75	0.70
0.8 atm	75%	71%	68%	64%
	8,956	5,264	4,392	4,163
3.0 atm	75%	70%	66%	61%
	4,828	3,901	3,729	3,825
8.0 atm	73%	67%	60%	53%
	3,709	3,510	3,726	4,135

Breakeven Weights - The breakeven weight as a function of power unit efficiency is shown in Figure 3. The breakeven weight indicates the SOFC power unit weight at which the aircraft fuel consumption would be the same as the current engine generators due to weight added. The highest breakeven weights occur for shorter flights. This occurs because the electrical generation is assumed constant but aircraft velocity during climb and descent is lower causing more fuel to be saved per mile compared to the higher velocity cruise phase. Figure 4 shows that current weight estimates are below breakeven weights indicating a potential to save fuel compared to engine generators. However, current weight estimates do not yet include insulation, connecting ducting and tubing and support structure which will possibly impact on the fuel savings.

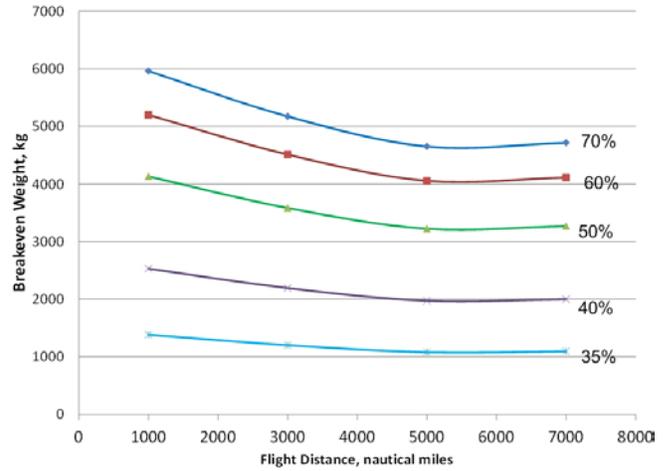

FIGURE 3. Breakeven Weights as a Function of Efficiency

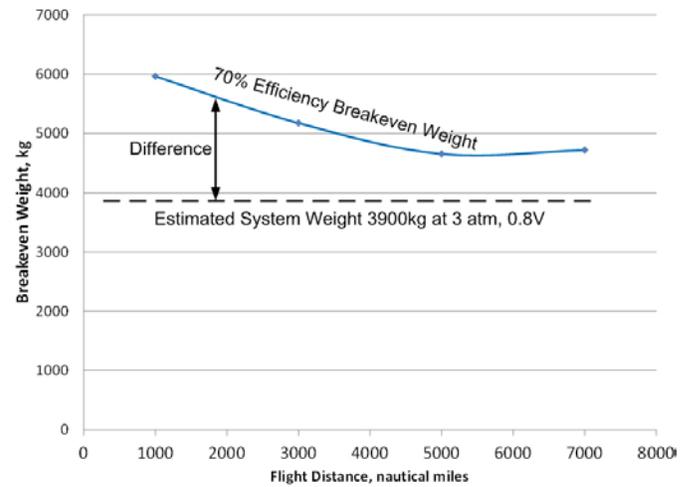

FIGURE 4. Comparison of Breakeven Weight to Estimated System Weight (3 atm, 0.8 V/cell)

Conclusions and Future Directions

- Existing SOFC technology is potentially capable of saving fuel during flight.
- Measurements of SOFC performance at high pressure will be made to support predictions of performance at high pressure.
- Additional modeling in the region of best performance will be conducted.
- A conceptual design will be developed to improve estimates of system weight.

XI. SYSTEMS ANALYSIS

XI.0 Systems Analysis Sub-Program Overview

Systems Analysis supports decision-making by providing a greater understanding of technology gaps, opportunities and risks, the contribution of individual technology components to the overall system (i.e., from fuel production to utilization), and the interaction of the components within the system. Analysis is also conducted to assess issues that cut across all the various aspects of hydrogen and fuel cell technologies—for example, examining how hydrogen and fuel cells can be integrated with the electrical sector and with other renewable fuels. Particular emphasis is given to assessing stationary fuel cell applications, the impact of fuel quality on fuel cell performance, and potential options for hydrogen infrastructure.

The Systems Analysis sub-program made several significant contributions to the Program during Fiscal Year (FY) 2011. The sub-program developed the hydrogen threshold cost, which represents the cost at which hydrogen fuel cell electric vehicles (FCEVs) are projected to become competitive on a cost per mile basis with the competing fuel-and-vehicle combination—gasoline in hybrid-electric vehicles (HEVs). This cost was determined to be \$2–\$4/gasoline gallon equivalent (gge, untaxed). Analytical tools, including HyDRA and the Macro-System Model, were updated and peer reviewed to support the analytical process. Infrastructure and early market analyses were conducted to better understand the supply and demand issues involved. A cost model was developed to evaluate the cost of removing impurities from the resource streams for hydrogen production. In addition, a study was initiated to evaluate the impact of biogas impurities on fuel cell performance and durability. The Greenhouse gases, Regulated Emissions, and Energy use in Transportation (GREET) model was modified to enable greenhouse gas emissions to be evaluated on a well-to-wheels basis for hydrogen energy storage from renewable electricity generation.

Goal

Provide system-level analysis to support the development of hydrogen and fuel cell technologies by: evaluating technologies and pathways, including resource and infrastructure issues; guiding the selection of RD&D projects; and estimating the potential value of RD&D efforts.

Objectives

- By 2011, enhance the Macro-System Model by including stationary electrical generation and infrastructure for long-term applications analysis.
- By 2011, complete a study comparing combined-heat-and-power (CHP) fuel cell systems with other CHP technologies.
- By 2012, evaluate the use of hydrogen for energy storage and as an energy carrier to supplement the energy and electrical infrastructure.
- By 2012, evaluate fueling station costs for early FCEV penetration to determine the cost of different hydrogen fueling pathways for low and moderate demand rates.
- By 2014, complete environmental studies needed for technology readiness of FCEVs—including analyses of potential greenhouse gas and criteria pollutant emissions reductions from the penetration of FCEVs in the light-duty vehicle fleet.
- By 2015, analyze the ultimate potential for hydrogen, stationary fuel cells, and FCEVs. (This analysis will address necessary resources, hydrogen production, transportation infrastructure, performance of stationary fuel cells and FCEVs, and the system effects resulting from the growth of hydrogen's market shares in the various sectors of the economy.)
- By 2018, complete analysis of Program performance, the cost status of various technologies, and the potential for use of fuel cells for a portfolio of commercial applications.
- On an ongoing basis, provide milestone-based analyses—including risk analysis, independent reviews, financial evaluations and environmental analysis—to support the Program's needs as new fuel cell applications achieve technology readiness.
- On an ongoing basis, periodically update life-cycle analyses of the energy use, petroleum use, and greenhouse gas and criteria pollutant emissions for various fuel cell applications and hydrogen production pathways. (These updates will include technological advances or changes in the underlying parameters.)

FY 2011 Status

Analysis conducted in FY 2011 included: updating the Hydrogen Threshold Cost; working with the DOE Vehicle Technologies Program to examine the life-cycle costs of various vehicle platforms including FCEVs; and identifying early markets for fuel cells and opportunities to reduce cost through various mechanisms, such as tax credits and other legislation. The Systems Analysis sub-program has transitioned from activities focused on key model development to the application of the developed models for completing critical analyses. The sub-program’s initial strategy has been effective in enabling the completion of a portfolio of analytical projects; several of these are discussed in the following section, “FY 2011 Accomplishments.”

FY 2011 Accomplishments

Development and Maintenance of Models

- The Macro-System Model, a dynamic engineering transition model, was updated to enable evaluation of the impacts of stationary fuel cells on electricity distribution. The Macro-System Model is used to simulate of the performance, cost, and the potential for reducing emissions and petroleum use by hydrogen and fuel cell technologies. The model uses a distributed architecture to link existing and emerging models for system components. Stationary fuel cell analysis capabilities were made possible by adding the National Renewable Energy Laboratory’s (NREL’s) Fuel Cell Power Model to the Macro-System Model.

Studies and Analysis

Market Analysis

- Oak Ridge National Laboratory analyzed the status and outlook for the U.S. non-automotive fuel cell industry by examining the impacts of government policies and funding. They found that fuel cell manufacturers have been able to achieve large cost reductions of ~50% over the last two to five years, as shown in Figure 1; and, they found that government funding and incentives have been key elements in enabling these cost reductions. They also found that continuation or enhancement of current policies, such as the investment tax credit and government procurement, combined with progress by industry will be necessary to establish a viable domestic fuel cell industry.
- Pike Research completed global and domestic analyses and studies of the fuel cell markets for material handling equipment, stationary power, and portable power. The studies identified increased growth for fuel cells in the domestic and international markets, as shown in Figure 2. In particular, the U.S. market grew more than 50% from 2008 to 2010 in terms of megawatts of fuel cell systems shipped.

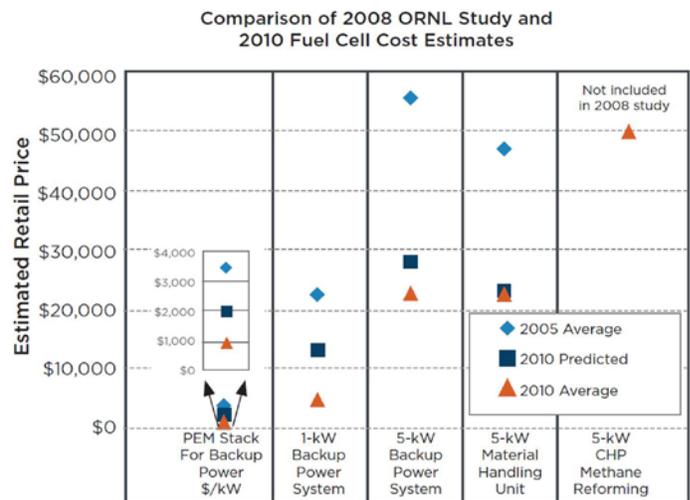

FIGURE 1. Cost Reductions in Early Market Fuel Cells. A 2008 study¹ by Oak Ridge National Laboratory assessed the average cost (in 2005) of fuel cells for early markets and then predicted what these costs would be in 2010, based on a model that included economies of scale and technology progress. An updated 2011 study² by the same group has estimated the average 2010 cost, which was shown to be equal to or even lower than the predictions. 2005 and 2010 averages based on estimates supplied by original equipment manufacturers. Predicted 2010 costs assumed total government procurements of 2,175 units per year, across all market segments. These predictions also assumed a progress ratio of 0.9 and scale elasticity of -0.2.

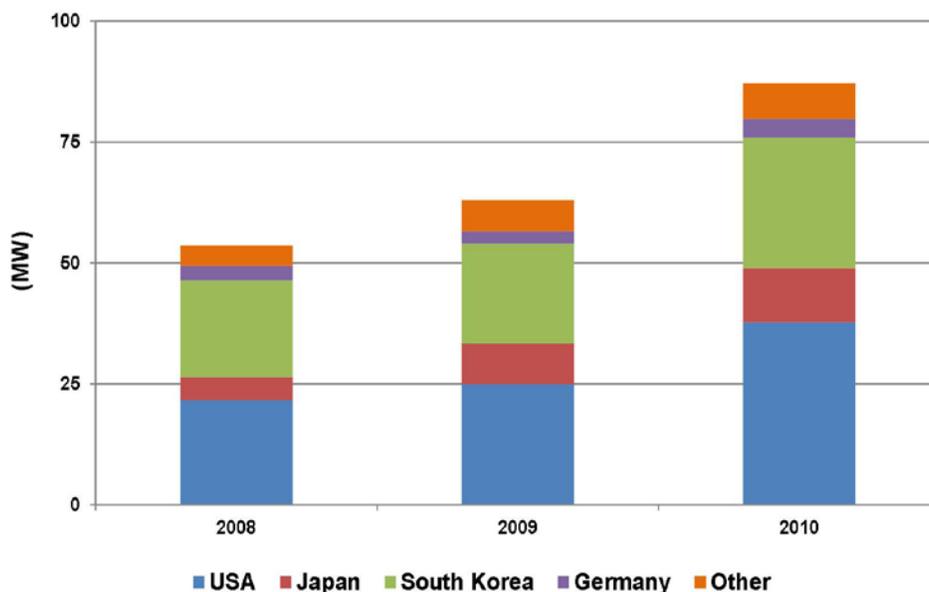

FIGURE 2. Megawatts of Fuel Cells Shipped.³ Fuel cell shipments, in terms of megawatts, continue to increase (~36% in 2010). U.S. shipments grew by more than 50% in 2010.

Infrastructure Analysis

- Infrastructure analysis conducted by NREL with the Scenario Evaluation and Regionalization Analysis model and Sandia National Laboratories revealed that synergies between fuel cells for stationary power generation and transportation could be realized in the early phases of market adoption of hydrogen for FCEVs. Widespread deployment of stationary fuel cell systems that co-produce power, heat, and hydrogen (“combined-heat-hydrogen-and-power” or CHHP systems) could reduce the problem of hydrogen availability in the early stages of transition to FCEVs. Model results indicate that the production of hydrogen from CHHP could result in smaller stations with higher capital utilization and lower hydrogen cost. Hydrogen produced this way could supplement hydrogen supplied from distributed natural gas-based steam methane reforming, particularly for the early years of FCEV penetration, when hydrogen demand and station sizes will be small. The analysis shows that hydrogen costs from CHHP units drop from \$7–\$9/gge in the early years when demand is low to \$5–\$7/gge in the later years when demand is higher.
- NREL examined cost reduction opportunities for components of hydrogen infrastructure by conducting a workshop on February 16–17, 2011, with a diverse group of stakeholders and through infrastructure cost assessment with a cost calculator of early market fueling stations. Stakeholders identified potential cost reductions of 50% through standardization and modular approaches of station design. They found that station costs could be reduced by an additional 20–30% by adopting a uniform permitting process. The results of the stakeholder input from the workshop and cost calculator will be published by the end of 2011.

Environmental Analysis

- Argonne National Laboratory analyzed the impact of feedstock quality on stationary fuel cell performance; identified contaminate removal solutions for sulfur, halogen and silica compounds; and estimated the costs associated with meeting the required feedstock quality specifications. The feedstocks primarily assessed included natural gas and biogas (from landfills and anaerobic digestion of wastewater). The key impurity analysis shows sulfur, siloxanes (organo-silica compounds), and halides are detrimental to the fuel cell

³ 2010 Fuel Cell Technologies Market Report, U.S. Department of Energy, June 2011, http://www1.eere.energy.gov/hydrogenandfuelcells/pdfs/2010_market_report.pdf.

anode. The level of impurities was found to vary among feedstocks. For example, halogens were found to be higher in landfill gas, while siloxane compounds are typically higher in biogas produced from wastewater treatment, as shown in Figure 3. Ammonia, CO, and hydrocarbons are less damaging for higher temperature fuel cells such as solid oxide and molten carbonate fuel cells. The costs of contaminant removal will be determined for different removal schemes.

Energy Storage Analysis

- NREL analyzed the potential of utilizing renewable electricity generation from various wind farm locations combined with hydrogen production and storage systems to provide renewable hydrogen for energy storage and vehicle applications. Results of the analysis exhibit the delivered cost of electricity from the capture of curtailed wind-generated electricity would range from \$0.13-\$0.29/kWh on a levelized basis, depending on the location of the wind farm. The equipment cost, including the electrolyzer cost, was found to be one of the key drivers for the electricity cost delivered from hydrogen energy storage systems.

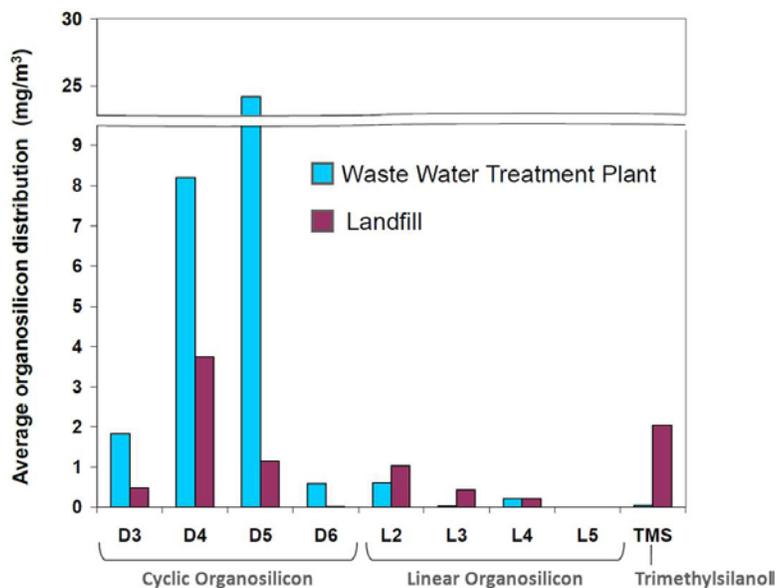

FIGURE 3. Impurities in Biogas Streams⁴

Programmatic Analysis

- A cost threshold for hydrogen was developed to assist DOE in focusing and prioritizing research and development (R&D) options. The cost threshold represents the cost of hydrogen at which FCEVs are projected to become competitive on a cost per mile basis with the competing fuel/vehicle combination—gasoline in HEVs. Its calculation includes projected vehicle fuel economies for HEVs and FCEVs, projected costs of gasoline, and projected incremental costs of FCEVs on a per-mile basis. Due to the uncertainty in all the parameters, both single-value and stochastic sensitivities were performed. The resulting hydrogen threshold cost is in the range of \$2-\$4/gge (in 2007 dollars). A graphical representation of the hydrogen threshold cost is shown in Figure 4.
- Pacific Northwest National Laboratory analyzed the commercial benefits of the DOE Fuel Cell Technologies (FCT) Program by tracking the commercial products, technologies, and patents developed from FCT R&D funding. The results show that more than 300 patents had been awarded and 30 products had been commercialized by 2011 as a result of research funded by FCT in the areas of fuel cells and hydrogen storage, production, and delivery (see Figure 5). These findings have been highlighted in the 2011 *Pathways to Commercial Success*⁵ report.

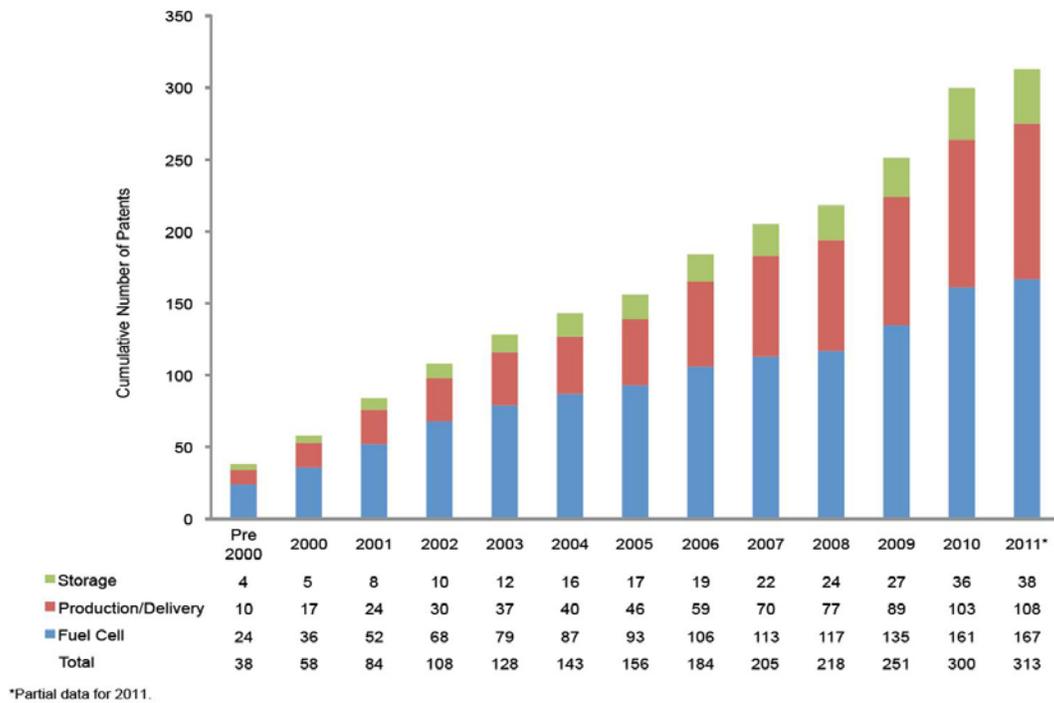

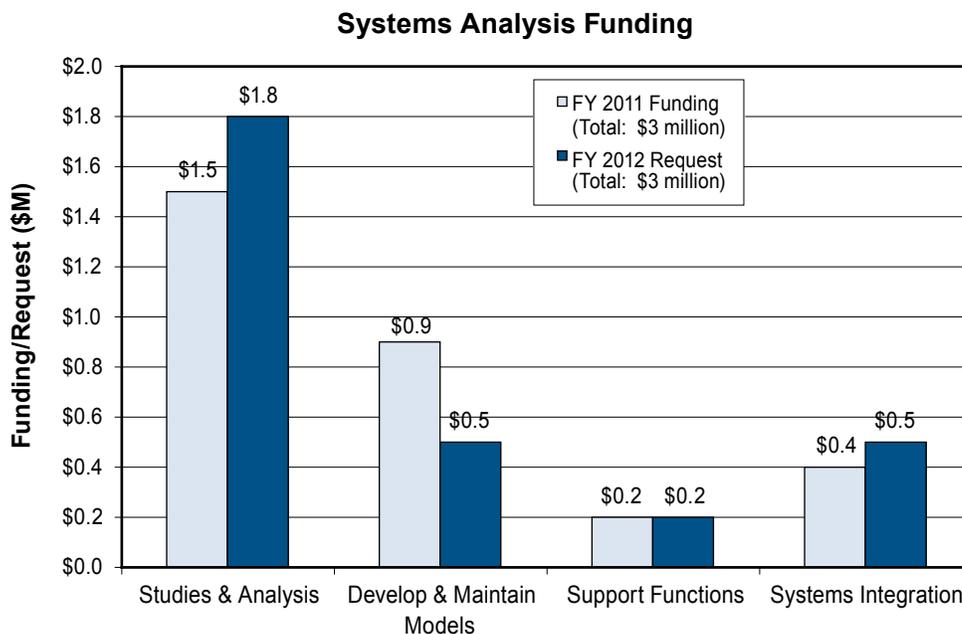

FIGURE 5. Cumulative Number of Patents Awarded as a Result of FCT Program Funding

Budget

The FY 2011 appropriation included \$3 million for Systems Analysis, and the FY 2012 request is \$3 million. The budget for Systems Analysis is consistent with the goals and objectives of the sub-program and allows the Program to assess fuel cell applications for energy storage, stationary power generation, specialty

applications, and light-duty transportation. The FY 2012 budget request includes funding for early fuel cell and hydrogen market and infrastructure analysis, as well as fuel quality evaluation, environmental analysis, overall program analysis, modeling, and systems integration.

FY 2012 Plans

In FY 2012, Systems Analysis will focus on conducting analyses to determine technology gaps for: fuel cell systems and infrastructure for different applications, and the use of fuel cells for energy storage and transmission. Analyses will include: assessing the tradeoffs and regional impacts of fuel cells with other alternative fuels; light-duty vehicle life-cycle costs for multiple platforms; socio-economic impacts of job creation based on fuel cell and hydrogen manufacturing, and the synergies of linking stationary fuel cell power generation with the electrical sector. New opportunities for using fuel cells for energy storage and integration with existing energy supply networks such as natural gas transmission will also be explored.

Subcontractors:

- The University of Tennessee, Knoxville, TN
- ICF, International, Washington, D.C.
- Fuel Cell Today, Royston, UK

Project Start Date: October 1, 2007

Project End Date: Project continuation and direction determined annually by DOE

Fiscal Year (FY) 2011 Objectives

- Analyze the status and prospects of the fuel cell industry and impacts of policies.
- Simulate market transformation to hydrogen fuel cell vehicles in the United States.
- Conduct systems analysis of fuel cell technologies.

Technical Barriers

This project addresses the following technical barriers from section 4.5 of the Fuel Cell Technologies Program Multi-Year Research, Development and Demonstration Plan:

(A) Future Market Behavior

Understanding the behavior and drivers of the fuel and vehicle markets is necessary to determine the long-term applications. Another major issue is the hydrogen supply, vehicle supply, and the demand for vehicles and hydrogen are all dependent and linked. To analyze various hydrogen fuel and vehicle scenarios, models need to be developed to understand these issues and their interactions.

(D) Suite of Models and Tools

The program currently has a group of models to use for analysis; however, the models are not sufficient to answer all analytical needs. A macro-system model is necessary to address the overarching hydrogen infrastructure as a system. Improvement of component

models is necessary to make them more useable and consistent.

(E) Unplanned Studies and Analysis

Every year, many analysis questions are raised that require analysis outside and, in some cases, instead of the plans made for that year. Many analysis questions need responses in brief periods of time particularly when they are driven by external requests or needs. A flexible capability to provide those results is necessary.

Contribution to Achievement of DOE Systems Analysis Milestones

This project will contribute to achievement of the following DOE milestones from the Systems Analysis section of the Fuel Cell Technologies Program Multi-Year Research, Development and Demonstration Plan:

Provide system-level analysis products to support hydrogen infrastructure development and technology readiness by evaluating technologies and pathways, guiding the selection of research, development and demonstration (RD&D) projects, and estimating the potential value of RD&D efforts:

- By 2015, analyze the ultimate potential for hydrogen and fuel cell vehicles. The analysis will address necessary resources, hydrogen production, transportation infrastructure, vehicle performance, and interactions between a hydrogen economic sector and other sectors.
- Provide milestone-based analysis, including risk analysis, independent reviews, financial evaluations and environmental analysis, to support the program's needs prior to technology readiness.
- **Milestone 26:** Annual model update and validation. (4Q, 2008; 4Q, 2009; 4Q, 2010; 4Q, 2011; 4Q, 2012; 4Q, 2013; 4Q, 2014; 4Q, 2015)
- **Milestone 39:** Annual update of Analysis Portfolio. (4Q, 2007; 4Q, 2008; 4Q, 2009; 4Q, 2010; 4Q, 2011; 4Q, 2012; 4Q, 2013; 4Q, 2014; 4Q, 2015)

FY 2011 Accomplishments

- Completed analysis of the status and outlook for the U.S. non-automotive fuel cell industry and quantified impacts of government policies on costs and production volumes.
- Completed analyses and assessments of markets, benefits and barriers to fuel cell deployment.

- Completed comparative lifecycle assessment of greenhouse gas emissions for fuel cell and internal combustion engine technologies.

Introduction

Hydrogen fuels cells for both automotive and non-automotive applications are novel technologies with potentially enormous social benefits in terms of reduced environmental impacts, energy security and sustainability of global energy resources. To be successful, hydrogen fuel cell technologies must further reduce costs and improve durability while at the same time overcoming the “lock-in” of established technologies, such as the petroleum-fueled internal combustion engine. Because the chief benefits of these technologies are public goods (i.e., environmental quality, national security) public policy will play a key role in the market transformation that must take place if hydrogen and fuel cells are to be successful.

Models for analyzing the transition to hydrogen and fuel cells are essential to understanding how such a market transformation could occur, over what time frame, and the roles of government, industry and consumers in the transition. Analytical tools are needed to understand the technological and economical prerequisites for a successful transition, as well as its costs and benefits. This project assists the Department of Energy by developing integrated models for simulating and analyzing the market transformation to hydrogen and fuel cells and conducting special analyses to develop new information about critical aspects of that phenomenon.

Approach

ORNL developed the HyTrans model to simulate the transition of light-duty vehicle transportation to hydrogen and to analyze scenarios and policies to achieve such a transformation. HyTrans is a non-linear dynamic optimization model that integrates the supply of hydrogen fuel, fuel cell vehicle manufacturing, and consumer demand. It simulates market barriers such as the “chicken or egg” problem (lack of hydrogen fuel and lack of hydrogen-powered vehicles), lack of diversity of vehicle choices during the early market transition, learning-by-doing and scale economies. HyTrans has been used to construct comprehensive scenarios of the transformation of the light-duty vehicle market and to measure the costs and benefits of such a transition.

ORNL has also conducted assessments of the status of fuel cells for non-automotive applications. These assessments included in-depth interviews with foreign and domestic fuel cell manufacturers and observation of their manufacturing facilities, data collection and construction of a model for simulating the evolution of fuel cell markets over

time, including competition with established technologies. The markets addressed include combined heat and power (CHP), uninterruptible and backup power, and materials handling.

Results

The most significant accomplishment of FY 2011 was the completion of an analysis of the status and prospect for the U.S. non-automotive fuel cell industry and the impacts of government policies. The non-automotive fuel cell industry, worldwide, has made impressive progress since a previous assessment in 2007 [1]. Still, the global industry is dependent on public policies and is likely to be for several years.

- Non-automotive fuel cell manufacturers are making progress in a limited number of markets: for proton exchange membrane (PEM) fuel cells, back-up and uninterruptible power (especially for telecommunications), material handling equipment (forklifts), micro-CHP; for larger phosphoric acid and molten carbonate fuel cells, CHP and grid-independent stationary power.
- All manufacturers have achieved large cost reductions of 50% or more over the past 2-5 years. Nonetheless, all manufacturers believe that costs must be further reduced by 40% to 50% in order to compete successfully in the marketplace without government support.
- In the current market, government incentives are essential to sustaining the U.S. fuel cell industry. This is likely to remain the case for the next five years. Given continued or enhanced incentives fuel cell manufacturers might achieve sufficient cost reductions to continue without government support sometime between 2015 and 2020.
- Most manufacturers believe that future cost reductions will come primarily through economies of scale and cost reductions in the supply chain, with technological advances playing a somewhat smaller role than in the past. Estimated scale elasticities (the percent reduction in cost for a 1% increase in annual production) are typically in the range of -0.2 to -0.3, implying that doubling output would reduce costs by 20% to 30%.
- Substantial improvements in the durability of fuel cells have also been achieved. PEM fuel cell stacks in backup power applications today are expected to operate under real-world conditions for 5,000 to 10,000 hour lifetimes. ENEFARM¹ systems have been operating for 20,000 hours in Japanese homes and are guaranteed for 40,000-hour lifetimes. Large-scale (>300 kW) fuel cells for CHP and stationary power already exceed 40,000 hours before requiring replacement. Still, manufacturers believe that durability must and can be further improved.
- Almost all of the manufacturers interviewed were operating well below their existing production capacity

¹ENEFARM is the brand name of Japan’s residential PEM fuel cell CHP product.

and all had the capability to expand capacity by 50% to 300% within one year.

- Today, fuel cell manufacturers are dependent on government incentives or government procurements for viability. Without policies such as the investment tax credit, California’s Self-Generation Incentive Program, research and development funding and government procurements, most companies’ sales would be drastically reduced.
- For U.S. manufacturers, the key domestic markets are in California and the northeast states. South Korea is an important overseas market today, with sizable potential markets in the European Union. In the backup power area, manufacturers believe that developing countries represent large potential markets.
- For fuel cell CHP and micro-CHP manufacturers, both purchase incentives and high electricity prices (or feed-in tariffs) are essential to creating a viable market.
- For PEM fuel cells in back-up power and material handling, the cost and availability of hydrogen is a significant impediment to commercial success. While the American Recovery and Reinvestment Act of 2009 (ARRA) and other programs have provided important incentives for purchasing fuel cells, the problem of hydrogen availability for non-automotive applications has not yet been adequately addressed.

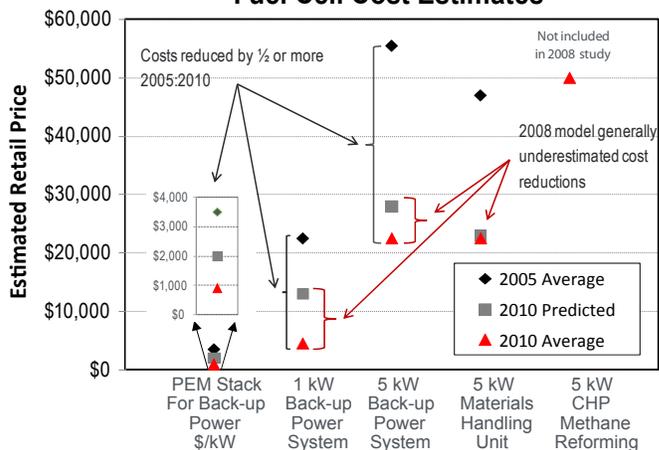

The 2008 report [1] estimated current costs for PEM fuel cell stacks and products and projected costs to 2010 based on assumed production levels, scale elasticities of approximately -0.2 and progress ratios of 0.95 for stack suppliers and 0.91 for manufacturers. These estimates, together with cost data gathered in the course of this study are shown in Figure 1. In every case, manufacturers have equaled or exceeded the manufacturing costs projected by the 2008 study. Large cost reductions have been achieved over the period 2005-2010:

- PEM stack costs have come down from roughly \$4,000/kW to \$1,000/kW.
- The cost of 1 kW backup power units have also been reduced by a factor of 4.
- The cost of 5 kW backup power units is down from about \$55,000 to \$22,000.
- The cost of 5 kW forklift systems has declined from \$48,000 to about \$22,000.

Similar cost reductions have been achieved by large, high-temperature fuel cell manufacturers. Fuel Cell Energy, for example, has reported cost reductions of a factor of five for its molten carbonate fuel cell product over the period 1996 to 2008 [2]. Foreign manufacturers whose governments have also supported fuel cell research, development and deployment have achieved similar cost reductions.

The model of the domestic fuel cell industry constructed for this study estimated that existing programs have

Comparison of 2008 ORNL Study and 2010 Fuel Cell Cost Estimates

2005 and 2010 averages based on estimates supplied by manufacturers 2010 predicted assumed government procurements of 2,175 units per year, total for all market segments. Predictions assumed a progress ratio of 0.9 and scale elasticity of -0.2.

FIGURE 1. Comparison of 2008 ORNL Study and 2010 Fuel Cell Cost Estimates

Estimated Impact of ARRA Purchases and ITC on the Cost of Fuel Cell Material Handling Equipment, 2009-2010

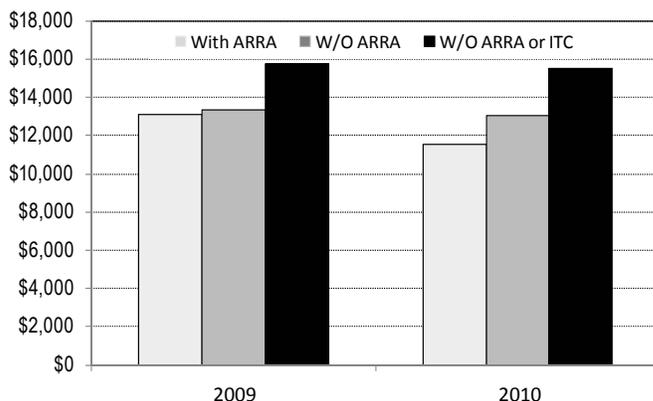

FIGURE 2. Estimated Impact of ARRA Purchases and Investment Tax Credit (ITC) on the Cost of Fuel Cell Material Handling Equipment in 2009 and 2010

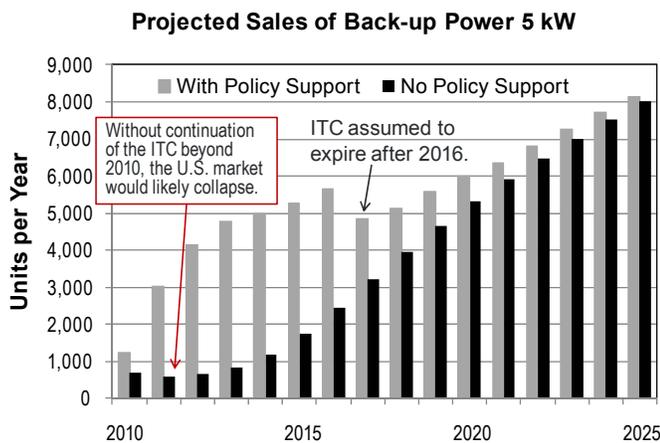

important beneficial impacts on the industry, without which the industry might not become sustainable. The ARRA has contributed to reducing costs of fuel cell manufacturers in the material handling and backup power segments (Figure 2). Without either the ARRA or the investment tax credit, it is estimated that the cost of fuel cell material handling systems would be about \$4,000 higher than the actual costs in 2010. Continuation of the investment tax credit through 2016 appears to be essential to sustaining a domestic fuel cell industry and could lead to a viable industry before 2020. The model’s estimates suggest that continuing current policies could lead to growing markets in all three applications (Figures 3-4).

However, production volumes, especially for material handling equipment but also for micro-CHP and large-scale CHP may not be sufficient to sustain manufacturers over the next 1-4 years. Enhanced incentives for fuel cell purchases should therefore be considered to increase the industry’s chances for successful transition to viability. The most promising policy for all types of fuel cells appears to be conversion of the investment tax credit now capped at 30% of capital cost to an uncapped \$3,000/kW tax credit. Feed-in tariffs are an especially attractive policy for large and small CHP.

Conclusions and Future Directions

The non-automotive fuel cell industry study documents the substantial progress domestic and foreign fuel cell manufacturers have made in reducing costs and improving performance over the past three years as well as the beneficial impacts of government policies. Still, the industry faces substantial barriers to market success, including further reducing costs via scale economies, learning by experience and for material handling applications, increasing the availability of moderately priced hydrogen.

Research in FY 2012 will focus on developing new scenarios of the potential transition to hydrogen, incorporating what has been learned about technologies and markets since the 2007 study. In particular, new scenarios will be developed to analyze the potential for hydrogen fuel cell, battery electric and grid-connected hybrid vehicles to compete in different market segments. In addition, the potential for maximum use of renewable energy in hydrogen and electricity production may be a focus. The HyTrans model will be used in these analyses but, in collaboration with the National Renewable Energy Laboratory (NREL), ORNL will explore the potential to combine ORNL’s MA3T model with NREL’s Scenario Evaluation, Regionalization and Analysis model to simulate the transitions at a much higher level of geographic detail and market segmentation.

Only ARRA purchases have been excluded from the “No Policy” case. Other government procurements prior to 2011 are included in both cases. Progress ratio of 0.9 and scale elasticity of -0.2. Number of manufacturers is assumed to be 3. Government and private purchases for demonstrations are 100 units/yr. in the policy case.

FIGURE 3. Projected Sales of 5 kW Backup Power Units With and Without Current Policies

Only ARRA purchases have been excluded from the “No Policy” case. Other government procurements prior to 2011 are included in both cases. Progress ratio of 0.9, scale elasticity of -0.2. Government and private procurements of 100 units/yr. for demonstrations continue in the policy case.

Subcontractors:

- IDC Energy Insights, Framingham, MA
- Energetics, Columbia, MD

Project Start Date: October 2010
Project End Date: September 2011

- Milestone 8 (System Analysis): Complete analysis and studies of resource/feedstock, production/delivery, and existing infrastructure for technology readiness. (4Q, 2014)

Accomplishments

- Convened a 1.5-day Market Readiness Workshop with more than 60 expert participants to discuss and prioritize technology market readiness and cost reduction opportunities.
- Collected feedback from panel discussions and breakout groups during the Market Readiness Workshop.
- Designed and distributed an Excel-based cost calculator that calculates the cost of hydrogen based on stakeholder responses to detailed cost questions about four general types of hydrogen stations: state-of-the-art, early commercial, larger stations, and more stations.
- Participated in meetings and supported the analysis process associated with the infrastructure rollout planning being undertaken by the California Fuel Cell Partnership (CaFCP).
- Integrated findings and feedback from all project activities into a final report.
- Initiated discussions about follow-up activities to better understand subtopics associated with hydrogen infrastructure market readiness.

Fiscal Year (FY) 2011 Objectives

- Collect stakeholder input on key issues pertaining to hydrogen infrastructure market readiness, with a focus on cost reduction opportunities.
- Identify quantitative and qualitative cost reduction opportunities associated with economies of scale, volume production, learning, standardization, streamlining station design and permitting processes, technology research and development, and other any other relevant factors.
- Communicate cost reduction opportunity findings in a cohesive final report.

Technical Barriers

This project addresses the following technical barriers from the Systems Analysis section of the Fuel Cell Technologies Program Multi-Year Research, Development and Demonstration Plan:

- (A) Future Market Behavior
- (C) Inconsistent Data, Assumptions, and Guidelines
- (B) Stove-Piped, Siloed Analytical Capability

Contribution to Achievement of DOE Systems Analysis Milestones

This project will contribute to achieving the following DOE milestone from the System Analysis and System Integration sections of the Fuel Cell Technologies Program Multi-Year Research, Development and Demonstration Plan:

Introduction

The cost of hydrogen infrastructure components required to support early markets for hydrogen fuel cell electric vehicles (FCEVs) is a significant barrier because of high investment risks and technology uncertainty. Past studies of the hydrogen transition have highlighted the importance of competitive early infrastructure costs to market transformation [1,2]. Cost and performance of infrastructure technologies have improved in recent years, especially with growth in emerging markets such as forklifts and telecommunications. An update on current status is necessary to inform the investment community and to improve the realism of scenario transition models.

Approach

This project examines cost reduction opportunities for hydrogen stations through three distinct activities: 1) conducting an expert workshop to discuss and prioritize opportunities, 2) distributing a cost calculator that enables stakeholders to provide quantitative feedback, and

3) coordinating with efforts at the CaFCP to integrate recent developments. These activities are summarized in the following.

The Hydrogen Infrastructure Market Readiness Workshop was held on February 16–17, 2011 in conjunction with the annual Fuel Cell and Hydrogen Energy Association conference. More than 60 attendees participated in two panel sessions during the afternoon of February 16; group discussions and breakout sessions were held all day on February 17. Each breakout group, with assistance from Energetics facilitators, used a voting system to prioritize opportunities. The mix of breakout group participants was predetermined to include diverse stakeholder perspectives in each group (see Figure 1). Breakout groups focused on the following key questions:

- What are the biggest opportunities to reduce the costs of hydrogen fueling stations over the next 2–5 years?
- What can we do to achieve the high-priority cost reduction opportunities?
- Who needs to do what when? What kind of help is needed? Is information sharing or coordination needed?

The Hydrogen Station Cost Calculator was distributed to a select group of experts to collect feedback on costs for stations designed to support early FCEV markets, as well as stations supporting expanding markets. The calculator was designed to enable experts to provide multiple levels of detail on cost and performance, and provides direct feedback on the implied cost of hydrogen (\$/kg) using the Hydrogen Analysis (H2A) discounted cash flow financial framework [3]. A Beta version of the calculator was distributed for review, and revisions were made based on suggestions for improvement before the final version was distributed. IDC Energy Insights distributed the calculator through a clean room mechanism, ensuring the anonymity of all responses and delivering only aggregate results to NREL staff. The third project activity, coordination with the CaFCP, has

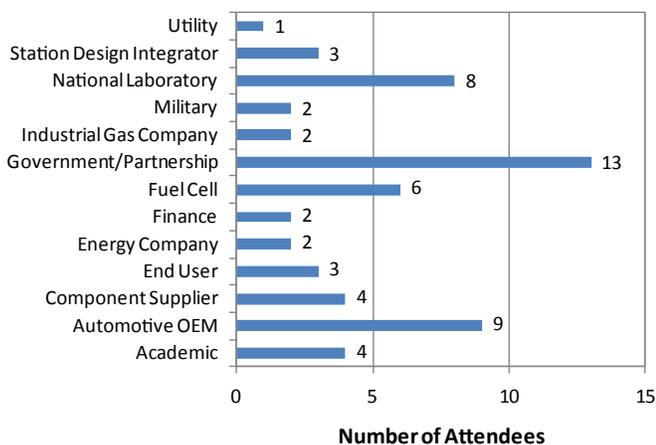

FIGURE 1. Distribution of Workshop Attendees by Stakeholder Group

occurred by attending planning meetings and providing California-specific infrastructure cost estimates based on NREL cost models.

Results

To date, complete results are available from the first activity only; feedback from the calculator is still being collected and the CaFCP is still being engaged. Figure 2 shows aggregate results of the Market Readiness Workshop cost reduction opportunity prioritization process; the number of opportunities in each category is shown on the vertical axis, and the number of points received through the prioritization process is indicated on the horizontal axis. Color coding indicates categories of a similar type. Two points were allocated to each opportunity identified during the panel sessions, and one point for each opportunity raised in the breakout groups. Additional points were added based on the voting process, with each breakout group attendee allocating three points in two prioritization sessions. With the choice of categorization shown in Figure 2, streamlining the station permitting process is a high-priority cost reduction opportunity. Other types of categorization, especially around station design (green boxes), would highlight other priorities. Examples of specific hydrogen station cost reduction opportunities are:

System Station Costs (Design, Performance Requirements)

- Eliminate station design/installation requirements with ultraconservative requirements.
- Increase the number of station components and equipment that have achieved third-party certification for use in hydrogen service.
- Target processes and components that cause station reliability problems (O-rings, infrared nozzles, etc.).
- Encourage modular station designs that harmonize requirements for small, medium, and large stations, and enable modular station expansion.
- Provide awards for networks of stations using the same (or a similar) design, rather than one-off projects.
- Harmonize and standardize dispensing equipment specifications.
- Increase the number of suppliers of hydrogen station components and systems.

Component Level Costs

- Reduce capital equipment costs, especially for high-pressure equipment.
- Reduce hydrogen storage costs (e.g., enable use of 14,000 psi storage; composite tanks).
- Reduce compressor capital, and operations and maintenance costs.

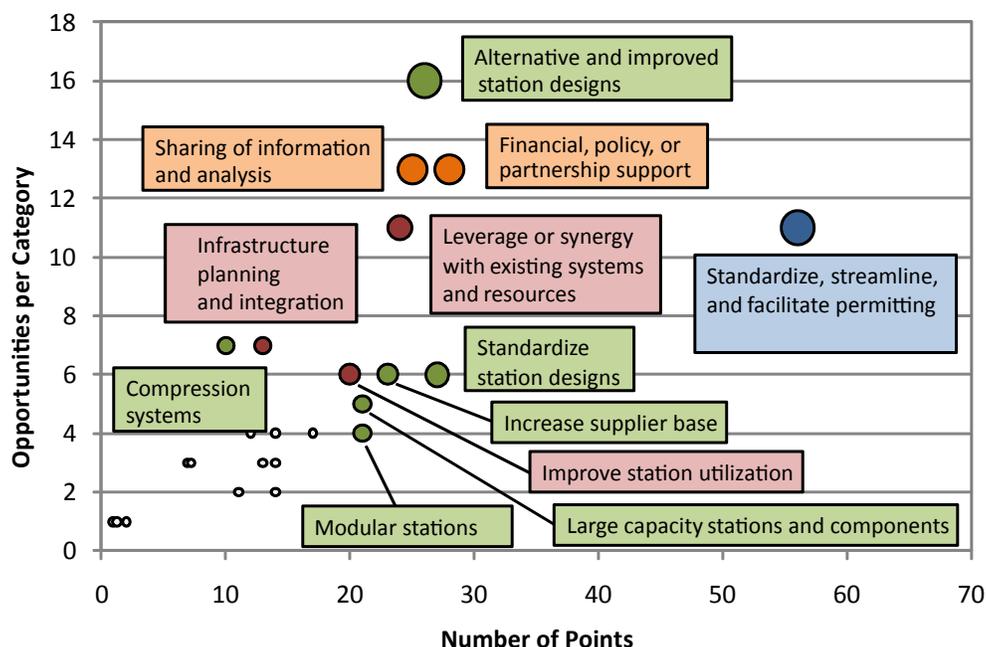

FIGURE 2. Summary of cost reduction opportunities collected from workshop breakout groups (vertical axis) and points allocated through voting process (horizontal axis).

Reduce Dispensing Costs

- Reduce planning and permitting costs (siting, cost of compliance).
- Institute a “type approval” approach for hydrogen stations to simplify and streamline the permitting process.
- Develop a model or models for a streamlined, uniform permitting process (written for permitting officials).
- Develop targeted, “plain language” information products and forums to educate fire marshals, permitting officials, municipal officials, the public, and the insurance industry about hydrogen stations.

Economies of Scale and Learning by Doing

- Modular approaches and standardized manufacturing can lead to as much as 50% cost reduction.
- More uniform permitting processes could reduce station costs by 20%–30%.
- Cut equipment operations and maintenance costs by 75% by using validated components.

Collaborative Actions

- Detailed station deployment plan – include automotive original equipment manufacturers, focused markets, potentially contractual, with a 5–10 year outlook.
- Early market hydrogen users group – webinar series, conferences, briefings to be posted on website, codes

and standards database, Annual Merit Review meeting-like exchange of information across industries.

Research and Development

- Design modular expansion stations.
- Design a targeted DOE program on large-scale compression.

Conclusions and Future Directions

NREL researchers have identified numerous diverse opportunities to further reduce the cost of hydrogen stations that are designed to serve early FCEV markets. These opportunities must be pursued through a variety of means, including technical design, codes and standards, and policy mechanisms. Station design and streamlining the permitting process appear to be two general categories that include multiple high-priority cost reduction opportunities. This project ends in FY 2011, but plans are to provide improved characterizations of distinct cost reduction opportunities through follow-up stakeholder workshops. All results and feedback will be compiled in a final report.

direction determined annually by DOE

Fiscal Year (FY) 2011 Objectives

The Scenario Evaluation, Regionalization and Analysis (SERA) model is a geospatially and temporally oriented analysis model that determines the optimal production and delivery scenarios for hydrogen, given resource availability and technology cost. The objectives of the most recent phase of the project are:

- Interoperability
 - Add functions to SERA to work with new HyDRA (Hydrogen Demand and Resource Analysis) [1] tool features.
 - Import detailed H2A (hydrogen analysis) [2,3] cost models into SERA.
- Infrastructure Integration
 - Develop cost submodels representing a variety of alternative infrastructure development pathways.
- Scenario Analysis
 - Hydrogen production from biogas.
 - Niches for combined heat, hydrogen, and power (CHHP).
 - Minimizing delivery cost of renewable hydrogen.
 - Implications of stakeholder behavior and consumer preferences.
 - Price points between competing technologies.

Technical Barriers

This project addresses the following technical barriers from the Systems Analysis section (4.5) of the Fuel Cell

Technologies Program Multi-Year Research, Development and Demonstration Plan:

- (B) Stove-piped/Siloed Analytical Capability
- (D) Suite of Models and Tools
- (E) Unplanned Studies and Analysis

Contribution to Achievement of DOE Systems Analysis Milestones

This project is contributing to achievement of the following DOE milestones from the Systems Analysis section of the Fuel Cell Technologies Program Multi-Year Research, Development and Demonstration Plan:

- **Milestone 3.** Begin a coordinated study of market transformation analysis with H2A and Delivery models.
- **Milestone 5.** Complete analysis and studies of resource/feedstock, production/delivery and existing infrastructure for various hydrogen scenarios.
- **Milestone 24.** Complete the linear optimization model (HyDS) to analyze the optimum production facilities and infrastructure for hydrogen demand scenarios.
- **Milestone 26.** Annual model update and validation.

FY 2011 Accomplishments

- Enhanced cost model:
 - Addition of biogas, CHHP, and wind cost models for hydrogen production.
 - Addition of rail and composite-tank truck delivery pathways.
 - New, advanced method for rapidly incorporating updates to H2A cost models into SERA.
- Added new submodels:
 - Vehicle choice
 - Vehicle stock
- Conducted first-of-kind studies:
 - Hydrogen production from biogas.
 - Niches for CHHP.
 - Minimizing delivery cost of renewable hydrogen.
 - Implications of stakeholder behavior and consumer preferences.
- Achieved significant enhancements in SERA usability:
 - Cleaner user interface.
 - Streamlined data storage mechanisms.

Introduction

The SERA model fills a unique and important niche in the temporal and geospatial analysis of hydrogen infrastructure build-out for production and delivery. It nicely complements other hydrogen analysis tools and is well suited to contribute to scenario analysis involving the temporally specific geospatial deployment of hydrogen production and transmission infrastructure. Its key capabilities are (i) an optimization of the physical build-out of hydrogen infrastructure; (ii) the unified treatment of production, transmission, and distribution; (iii) the ease with which new technologies can be added to an analysis; (iv) the consistent physical and economic computations; (v) the ability to estimate costs and cash flows; (vi) the spatial and temporal resolution of hydrogen infrastructure networks; (vii) regional specificity; and (viii) the allowance for exogenously specified urban hydrogen demands. Its internal architecture is flexible, and it is compatible with geographic information systems (GIS) and the H2A models [2,3]. SERA is designed to answer questions such as: Which pathways will provide least-cost hydrogen for a specified demand? What network economies can be achieved by linking production facilities to multiple demand centers? How will particular technologies compete with one another?

Approach

In order to answer such questions, SERA supports analyses aimed at identifying optimal infrastructure to meet specified annual urban hydrogen demands, perhaps coupled to other multiple objectives and constraints. Cash flows are computed, detailed by infrastructure component, city, and region, and these provide insights into components of hydrogen costs, which are determined by year, volume, and locality. Four methods of long distance hydrogen transport are considered: pipeline, gaseous truck, liquid truck, and railroad. The major use of SERA is for studying potential turning points in infrastructure choice via sensitivity analysis on infrastructure, feedstock, and fuel cost inputs

in the context of the complex transient and transitional interactions between increasing hydrogen demand and hydrogen infrastructure construction. With carefully constructed input data sets, SERA can also weigh tradeoffs between investments in various infrastructure types, given policy constraints (e.g., greenhouse gas). Figure 1 shows the interrelationship between the input data for SERA and the algorithms applied to them in order to compute the delivered cost of hydrogen. The infrastructure networks are optimized using a simulated-annealing algorithm that explores the large set of potential build-out plans that meet the input requirements for hydrogen delivery at cities over time. The hydrogen transport computations are based on graph-theoretic algorithms for determining optimal flows in networks. The cash flow computations rely on standard discounting approaches. Figure 2 shows sample SERA output in the form of an optimized hydrogen infrastructure network.

Results

We finalized a study that examines the relative cost-effectiveness of supplying hydrogen refueling stations via CHHP or on-site steam methane reforming (SMR) for a large urban area, under three fuel cell electric vehicle (FCEV) penetration scenarios. The major conclusions of this work are: (i) CHHP-based hydrogen production for use in nearby hydrogen refueling stations typically only has cost advantages over on-site SMR hydrogen production at some of those refueling stations, particularly for the early years of FCEV penetration scenarios where hydrogen demand and station sizes are initially small; (ii) variations in SMR or CHHP facility and energy-input costs can dramatically affect the overall cost of hydrogen, but they do not affect the mix of CHHP and SMR deployment as strongly; and (iii) for these scenarios and this study region, hydrogen costs typically drop from slightly above \$6/kilogram (kg) in early years to below \$5/kg in later years.

Furthermore, we finalized a study of the SERA biogas capability. This involved (i) provisionally incorporating the

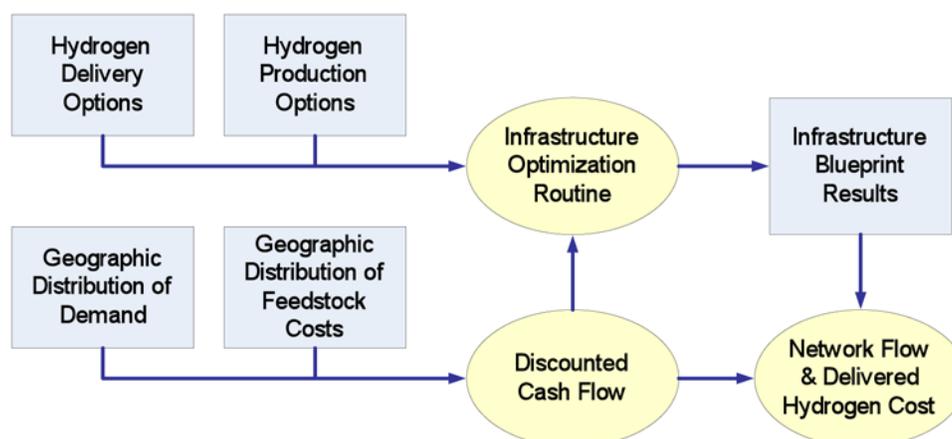

FIGURE 1. SERA Input and Output Data and Algorithms

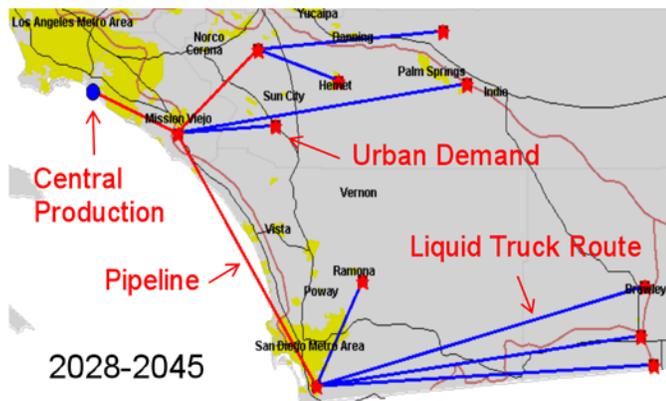

FIGURE 2. Illustrative Hydrogen Infrastructure Network Output from SERA

latest NREL biogas systems characterization into SERA, (ii) performing an illustrative analysis of infrastructure build-out highlighting the significance of biogas pathways, and (iii) developing insights for future in-depth studies involving biogas pathways. SERA uses cost estimates from the H2A biomethane systems model in conjunction with those from the H2A production model to evaluate the delivered cost of biogas-originated hydrogen. In the sample analysis that we performed (on a test case of Midwestern cities), the optimal choice of infrastructure often hinges upon the difference between biogas and natural gas prices: when the biogas price, plus the processing cost to biomethane, is less than the natural gas price, the biogas pathways have lower costs. In general, the most competitive biogas scenario is when a single large biogas plant supplies a dozen or more (typically small) on-site SMR plants.

We also explored three diverse avenues for the production of hydrogen from renewable resources in the context of substantial adoption of fuel cell vehicles and the large scale use of renewable for electricity production: (i) the production of hydrogen from wind-generated electricity that would have been curtailed by electric power grid congestion, (ii) the production of hydrogen directly from wind resources without the co-production of electricity, and (iii) co-production with a balance between electricity transmission and electrolysis. In this context, we varied the technological characteristics of the hydrogen production in considering current, future, and “breakthrough” situations. We found total delivered costs in the \$4-\$10/kg range (see Figure 3), along with a diverse use of infrastructure that highlights the niches where particular delivery pathways are most cost effective. The use of curtailed wind energy can lower the delivered cost of hydrogen dramatically, although sufficient curtailed resource is not available to allow wind-produced hydrogen to supply the majority of hydrogen in high penetration FCEV scenarios.

We completed the development of vehicle-choice and vehicle-stock capabilities for SERA. The objectives of this effort were to (i) incorporate the latest version of the

Automotive Deployment Option Projection Tool (ADOPT) [4] vehicle choice model into SERA, (ii) verify that output from the SERA vehicle choice model matches that from ADOPT, (iii) integrate the new vehicle choice model with a existing vehicle stock model that tracks the ageing and energy use of vehicles, and (iv) develop insights for future studies involving vehicle choice and stock. This allows us to generate regional market shares for new vehicles over time. The new vehicle choice model can handle any user-defined set of vehicle makes and models, any user-defined set of vehicle types (e.g., internal combustion engines, FCEVs, electric vehicles), and any user-defined set of geographic regions (e.g., zip codes, counties, states, census regions, national). It aggregates the user-defined geographic regions into larger regions, generates annual market shares, estimates splits between fuel types, and provides output suitable for input into the SERA vehicle stock model. Furthermore, it supports the future inclusion of alternative algorithms for vehicle choice if those are deemed necessary for an analysis study. The current version of the SERA vehicle choice model exactly reproduces the output of the ADOPT model. The output of the SERA vehicle choice and stock models is used as input for SERA-based infrastructure optimization studies.

Finally, we made major progress automating the computations of hydrogen costs based on the H2A models, which are encoded as Excel spreadsheets. This capability is

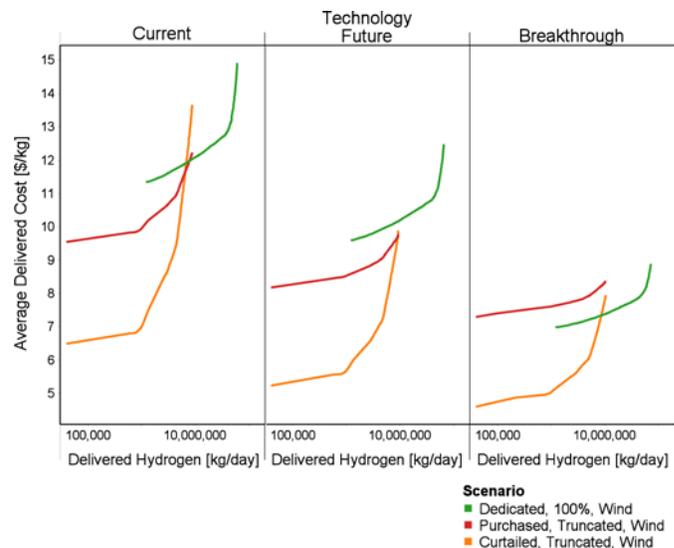

FIGURE 3. Effective-cost curves for wind-hydrogen scenarios. The “dedicated” cases are when the whole wind resource is used for hydrogen production; the “purchased” cases are when the curtailed wind resource is supplemented with additional electricity purchased from the wind farm; and the “curtailed” cases are when only the curtailed wind energy is used for electrolysis. The “current” and “future” technology cases roughly correspond to estimated 2010 and 2030 costs; the “breakthrough” technology case assumes costs substantially lower than the “future” case.

invaluable in keeping the cost inputs to SERA completely in synchronization with the latest H2A production and components models.

Conclusions and Future Direction

In summary, SERA is an effective, integrated, cross-cutting model for optimization-analysis studies of hydrogen infrastructure build-out compatible with the H2A models. It searches for optimal combinations of hydrogen production and transmission infrastructure to meet time-varying demand in urban areas over a region.

The SERA software is now essentially complete, but continued use of the tool in scenario studies requires regular updating of H2A and other cost inputs, software modifications to take advantage of new HyDRA features, and minor usability enhancements in response to analysts' requests. SERA will be applied to more complex deployment scenarios such as (i) identifying regional niches for production technologies and delivery infrastructure and (ii) assessing the influence of feedback from computed delivered costs of hydrogen to consumer and stakeholder decisions. We also plan collaborative exchange of data and scenarios assumptions with other models for the conduct of integrated multi-fuel studies, particularly when they involve scenarios with opportunities for addressing cost barriers in early years of FCEV transition.

Project Start Date: December 1, 2007
Project End Date: September 30, 2012

- **Milestone 7:** Analysis of the hydrogen infrastructure and technical target progress for the hydrogen fuel and vehicles. (2Q, 2011)
- **Milestone 8:** Complete analysis and studies of resource/feedstock, production/delivery and existing infrastructure for technology readiness. (4Q, 2014)

Accomplishments

- Sandia National Laboratories developed a dynamic tool for analyzing the potential impact of an emergent hydrogen fuel infrastructure on the existing energy infrastructures.
- Developed models of the behavior of natural gas, refined petroleum, hydrogen, and electricity generation cost for eight geographic regions in the U.S.
- Incorporated a light-duty vehicle adoption model for hydrogen fuel cell (HFCV), plug-in hybrid electric (PHEV), battery electric (BEV) and a new generation of conventional vehicles that meet the 2016 Corporate Average Fuel Economy regulation [1]. Added market segmentation to assign alternative vehicles to three vehicle classes: small cars, large cars, and trucks.
- Quantified the impact of large-scale HFCV adoption on key metrics such as petroleum use and carbon emissions and analyzed the relative benefits of BEV and HFCV. Our analysis shows that HFCVs could enable nearly 10-fold larger savings in petroleum use, as compared to BEVs.
- Examined impact of combined power and hydrogen production from stationary fuel cells on early HFCV market.

Fiscal Year (FY) 2011 Objectives

- Develop models of interdependent energy infrastructure systems.
- Analyze the impacts of widespread deployment of a hydrogen fueling infrastructure and hydrogen fuel cell vehicle fleet.
- Analyze the impacts of stationary fuel cell systems for distributed power.

Technical Barriers

This project addresses the following technical barriers from the Systems Analysis section of the Fuel Cell Technologies Program Multi-Year Research, Development and Demonstration Plan:

- (A) Future Market Behavior
- (B) Stove-Piped/Siloed Analytical Capability
- (E) Unplanned Studies and Analysis

Contribution to Achievement of DOE Systems Analysis Milestones

This project will contribute to achievement of the following DOE milestones from the Systems Analysis section of the Fuel Cell Technologies Program Multi-Year Research, Development and Demonstration Plan:

- **Milestone 5:** Complete analysis and studies of resource/feedstock, production/delivery and existing infrastructure for various hydrogen scenarios. (4Q, 2010)

Introduction

This systems analysis task is designed to examine the impact of emerging hydrogen infrastructure and fuel cell vehicles on key metrics, such as petroleum use and carbon emissions. To make a meaningful assessment of the benefits of fuel cell technologies, potential competing technologies must be included in the analysis. For this reason, we include multiple hydrogen and electricity production pathways and a range of vehicle sizes and powertrain combinations. It is also important to consider the time scale for technology development and deployment. Therefore our analysis includes time-dependent data for the deployment of potential fuel production and delivery pathways along with the evolution of the light-duty vehicle fleet.

Sandia National Laboratories (SNL) developed a system dynamics (SD) model for studying the competition of

HFCVs, PHEVs, BEVs, and advanced gasoline vehicles and the resulting impact on energy infrastructures. In addition, our model includes the possible adoption of stationary fuel cell systems for distributed power and hydrogen fuel production. To demonstrate the utility of the SD approach, in FY 2009 and 2010 SNL analyzed the likely impact on the California markets for gasoline, natural gas, and electricity. This state was selected because it is home to one or more “lighthouse” cities for early hydrogen adoption, and because of the interdependencies between electricity and natural gas infrastructures (a significant fraction of electricity generation is derived from natural gas boilers and gas turbines). Our current work expands on the analysis to the national scale, with a regionally differentiated model that can examine geographic differences in vehicle fleet composition and transportation energy sources.

Approach

We use an SD model to simulate the future vehicle fleet composition [2]. The model is comprised of three main submodules: energy sources, fuels, and vehicles. The vehicle portion of the model calculates the changing composition of the vehicle fleet, in part due to the cost of fuel calculated by the fuel submodule. The cost of the fuels changes in response to changing demand from the vehicle model, with both positive and negative feedback elements. Positive feedbacks include factors such as decreasing cost of hydrogen delivery with increasing infrastructure utilization, while negative feedback elements include competition and exhaustion of primary energy sources. We consider multiple pathways to generate hydrogen and electricity, and the model uses a cost-based choice function to allocate new production capacity. For hydrogen production, we currently model natural gas distributed steam-methane reforming and centralized electrolysis from wind power.

The SD model chooses future vehicle sales by applying a multinomial logit choice model based on the amortized purchase cost, penalty factors (e.g. for low vehicle range) and the annual fuel cost [3]. This choice function allocates sales among the various combinations of vehicle powertrains and sizes included in the model. The cost of fuels and the purchase cost of the vehicles change over time, which causes

the distribution of powertrain choice to evolve over time. A summary of vehicle efficiency assumptions is shown in Table 1. The model allows for analysis of the sensitivity to input assumptions by using multiple model runs with variation of input parameters, using Latin hypercube sampling of the input space.

Results

The projected evolution of the light-duty vehicle (LDV) fleet over time is shown in Figure 1. Our baseline case assumes moderate growth in the vehicle fleet, at a net rate of 0.9%, equal to the estimate for overall U.S. population growth [4]. The overall growth rate is a result of an annual vehicle sales rate of 6.9% per year and a scrap rate of 5.8% per year. The baseline case also assumes that the price of crude oil starts at \$90/barrel and increases (in constant dollars) \$3/barrel per year. In this baseline case, alternative fuel vehicles (AFVs) make up approximately 50% of the LDV fleet by 2050. The dominant AFV in 2050 is the HFCV, with nearly 100 million vehicles in service. The PHEV40 and BEV vehicles’ market penetration is lower in large part due to unavailability of larger-sized vehicles, while PHEV10

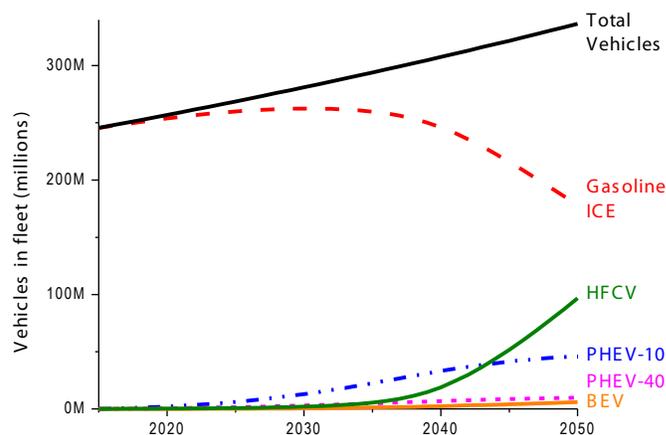

FIGURE 1. LDVs in the U.S. by powertrain for the baseline case. By 2050, approximately 50% of the vehicles in the fleet are AFVs.

TABLE 1. Analysis Assumptions for Vehicle Fuel Efficiency in 2010, 2016, and 2035

MPGe in 2010/2016/2035	Gasoline ICE	HFCV	PHEV10 Gas (77%) Elect (23%)	PHEV40 Gas (37%) Elect (63%)	BEV
Small Car	36/42/45	69/71/76	41/45/56 (gas) 84/102/136	30/34/47 (gas) 94/110/148	99/110/148
Large Car	18/30/39	69/71/76	35/39/47 72/87/116	25/29/40 80/94/126	N/A
Truck	18/30/39	69/71/76	20/23/28 42/51/68	N/A	N/A

MPGe – miles per gallon equivalent; ICE – internal combustion engine; N/A – not applicable

vehicles enter into the fleet in significant numbers due to their lower purchase price. The vehicle sales for the baseline case are shown in Figure 2. PHEVs initially make up most of the AFV sales, however HFCV sales greatly increase, starting in 2035. By 2050, HFCV sales make up over half of all new LDV sales. The shape and timing of the HFCV sales curve is consistent with prior studies by Greene *et al* [5]. It is important to note that the sales of HFCV are highly dependent on the assumption of rising petroleum prices. If crude oil prices remain constant at \$90/barrel, our results show little (<5%) penetration of AFVs (data not shown).

The impact of the significant AFV sales in the baseline case is shown in Figure 3. Both LDV carbon emissions and gasoline consumption show significant decreases (42% and 56%, respectively) relative to the start of the simulation, despite the fact that the total number of vehicles rises 37% over the 35-year simulation run. By 2050, LDV gasoline consumption has dropped to less than 60 billion gallons per year. This level of emissions and petroleum reductions is enabled by AFVs, however predicted improvements to conventional gasoline vehicles are responsible for a large portion of the savings. Gasoline vehicle improvements alone would result in 25% reductions in both gasoline use and carbon emissions in 2050 (relative to 2015).

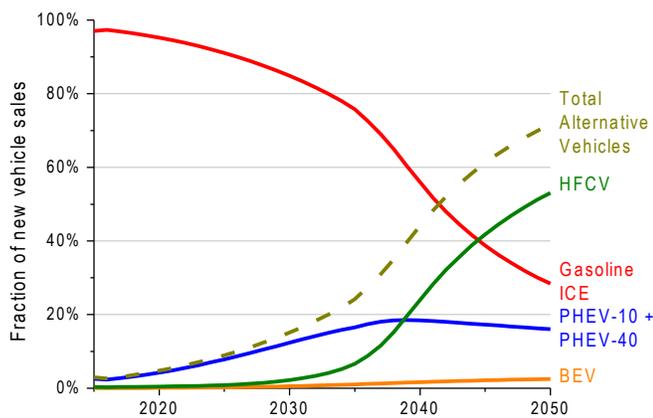

FIGURE 2. Fraction of LDV sales by powertrain for the baseline case. PHEVs are the dominant AFV at the start of the simulation, however HFCV sales rise quickly starting in 2035.

In the baseline case, we assume all AFV powertrains (PHEV10, PHEV40, BEV, and HFCV) are available. However, AFV technologies require substantial infrastructure investment and research and development progress, and it is possible that not all AFV powertrains will reach large-scale commercial viability. We examine the effects of powertrain unavailability in Figure 4 and Table 2. These data show the effect of not having BEVs, HFCVs or both on key metrics. As shown in Figure 4, the reduction in carbon emissions due to HFCV availability is over 5-fold greater than the reduction due to BEV. In Table 2, the impact of powertrain availability on LDV gasoline consumption is shown and the HFCVs show almost an order of magnitude greater reduction.

Conclusions and Future Directions

Under our baseline case of moderate oil price increases, our analysis predicts 50% hydrogen fuel cell and electric vehicles by 2050. The large-scale market penetration of HFCVs would allow significant greenhouse gas emission and gasoline use reductions, with over 50% decrease in gasoline use in 2050 (relative to 2015 levels). Increasing oil prices

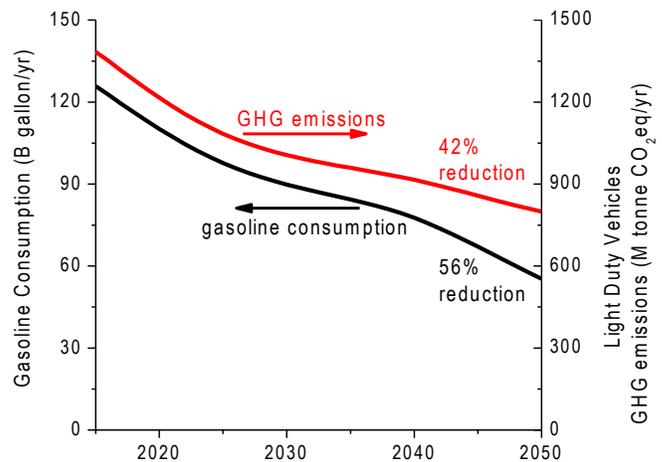

FIGURE 3. Gasoline consumption and carbon emissions from the LDV fleet in the baseline case. Reductions shown are relative to the values in 2015.

TABLE 2. Annual LDV Gasoline Consumption under Different Assumptions for Gasoline Price Projections (Constant Dollars) and Vehicle Powertrain Availability

Oil Price, 2015→2050	ICE + PHEV	ICE + PHEV + BEV	ICE + PHEV + HFCV	ICE + PHEV + HFCV + BEV
\$90/bbl, no increase	92.7 B gal/yr	92.6 B gal/yr	91.4 B gal/yr	91.3 B gal/yr
\$90/bbl → \$195/bbl	84.5 B gal/yr	82.6 B gal/yr	56.2 B gal/yr	55.3 B gal/yr
\$90/bbl → \$265/bbl	79.6 B gal/yr	75.6 B gal/yr	40.5 B gal/yr	39.2B gal/yr

bbl - barrel

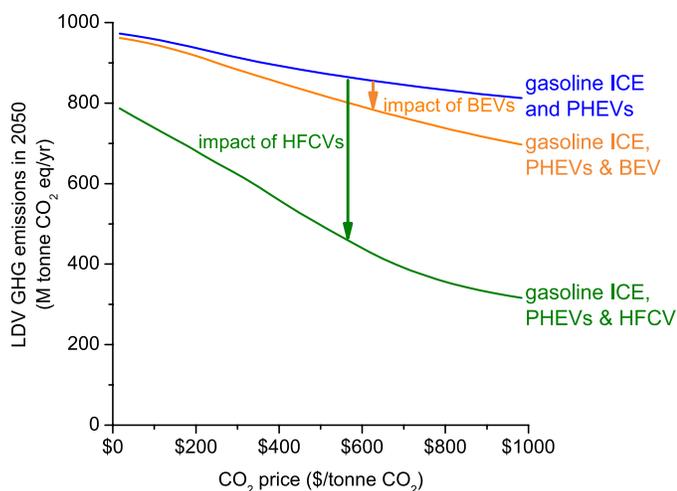

FIGURE 4. Carbon emissions as a function of carbon price in cases with different powertrain availability. The highest emissions are for the scenario in which only gasoline ICE and PHEVs are available (no HFCVs or BEVs). The middle line shows the emissions with gasoline ICE, PHEV and BEV vehicles (no HFCVs), and shows moderate reductions in carbon emissions due to BEV availability. The lowest line corresponds to the scenario with gasoline ICE, PHEV and HFCV vehicles (no BEVs). The impact of HFCV availability is much greater than BEV availability.

(and/or policies that give a price to carbon) are needed for significant numbers of HFCVs (or AFVs) to penetrate the LDV fleet. Our analysis predicts HFCVs will have much larger effect than BEVs on both gasoline consumption and LDV carbon emissions.

The model described in this report analyzes a subset of possible hydrogen production pathways, limiting our ability to model hydrogen infrastructure development and also limiting analysis of carbon-neutral transportation options. Future work will include more energy sources and production processes, with an emphasis on low-carbon hydrogen production options, so that infrastructure requirements and potential limiting factors for hydrogen fuel cell technologies will be better understood.

Project Start Date: October 2008

Project End Date: Project continuation and
direction determined annually by DOE

www.nrel.gov/wind/integrationdatasets/western/methodology.html.

- Cost estimates were developed for wind turbines, transmission lines, storage cavern development, electrolyzers, fuel cells and auxiliary equipment based on literature values.
- Two primary scenarios were developed and analyzed for the four wind farms.
 - Load leveling of the wind farm electrical output using hydrogen for electricity storage.
 - Hydrogen production via electrolysis used as dispatchable load for times of high wind output.
- The NREL Fuel Cell Power Model (http://www.hydrogen.energy.gov/fc_power_analysis.html), which combines hourly energy analysis of various generators and loads with the H2A discounted cash flow analysis tool, was used to calculate the levelized cost of all output energy (electricity and/or hydrogen) from the wind farms and storage systems.

Objective

Use analysis of scenarios for renewable electricity generation coupled with hydrogen systems to find opportunities for cost savings and other benefits of hydrogen energy storage and renewable hydrogen for vehicles.

Technical Barriers

This project addresses the following technical barriers from the Systems Analysis section (4.5) of the Fuel Cell Technologies Program Multi-Year Research, Development and Demonstration Plan:

- (B) Stove-Piped/Siloed Analytical Capability
- (D) Suite of Models and Tools
- (E) Unplanned Studies and Analysis

Technical Targets

The update of the H2A models directly supports the following milestones from the Systems Analysis function from FY 2004 through FY 2016.

Milestone 26	Annual model update and validation. (4Q, 2008; 4Q, 2009; 4Q, 2010; 4Q, 2011; 4Q, 2012; 4Q, 2013; 4Q, 2014; 4Q, 2015)
Milestone 39	Annual update of Analysis Portfolio. (4Q, 2007; 4Q, 2008; 4Q, 2009; 4Q, 2010; 4Q, 2011; 4Q, 2012; 4Q, 2013; 4Q, 2014; 4Q, 2015)

FY 2011 Accomplishments

- Four case study (theoretical) wind farms were identified using the NREL Western Wind Dataset ([http://](http://www.nrel.gov/wind/integrationdatasets/western/methodology.html)

Introduction

In FY 2008, NREL began investigating the use of hydrogen as an energy storage mechanism for electric utilities. In this application, various system configurations were modeled for producing hydrogen from renewable energy via electrolysis and storing it. The stored hydrogen can later be converted back to electricity using fuel cells to meet peak electricity demand. In subsequent analyses, NREL evaluated the costs of competing energy storage technologies (batteries, compressed air energy storage, and pumped hydro), additional fuel cell types, and investigated the potential dual benefit of producing excess hydrogen for the vehicle market (see reference [1]). This work builds on previous studies and incorporates more realistic analysis of the impacts of variable wind farm output. Four theoretical wind farms of various sizes and proximity to demand centers are analyzed for two primary scenarios: (1) hydrogen for energy storage; and (2) hydrogen production for transportation using otherwise curtailed wind-generated electricity.

Approach

Four theoretical wind farms were identified using the Western Wind Dataset. Groups of 10, 3-MW turbines were aggregated to the desired total wind farm size and the 10-minute power output data from the dataset was averaged to 1-hour data to create one hourly dataset for each wind farm (see Table 1 and Figure 1).

TABLE 1. Four Theoretical Wind Farms Used in the Energy Analysis

Location	Size (Nameplate Capacity MW)	Capacity Factor	Dedicated Transmission Line Distance (miles)
North Portal, ND	1050	42%	1,000
Wyoming	1620	41%	300
Oklahoma	330	37%	300
Palmdale, CA	450	39%	50

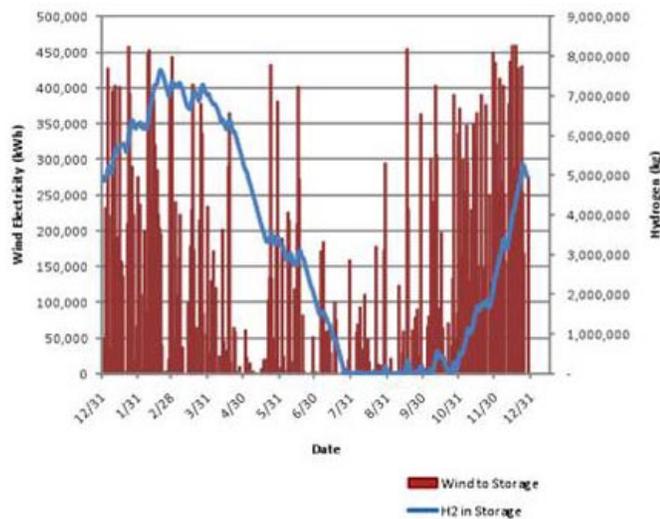

FIGURE 1. Curtailed Electricity and Hydrogen Storage use for the North Dakota Wind Farm

The Fuel Cell Power model calculates the levelized, profited cost of energy output from the system being analyzed. A “base case,” in which there is no storage system or hydrogen production, was analyzed for each wind farm. The amount of electricity curtailed is determined by the capacity of the dedicated transmission line for the wind farm. In this analysis the transmission line capacity was varied from 100% to 55% of the nameplate capacity rating of the wind farm, resulting in curtailment of 0% to ~25%. The amount curtailed at each transmission line size varied depending on the specific wind profile for that site. The base case provided a baseline cost of delivered electricity for the wind farm, taking into account the unrealized value of the curtailed electricity. Additional costs to install the storage system or electrolyzer are offset by the additional revenue from capturing some value of the curtailed wind. Thus, the primary cost metric for the analyses answers the question of whether the revenue from the storage system or hydrogen fully offsets the cost of installing additional equipment.

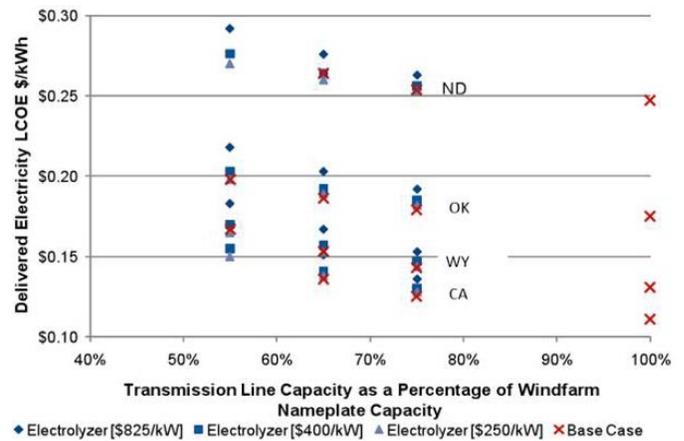

FIGURE 2. Levelized Cost of Delivered Electricity for the Four Wind Farms at Various Transmission Line Capacities

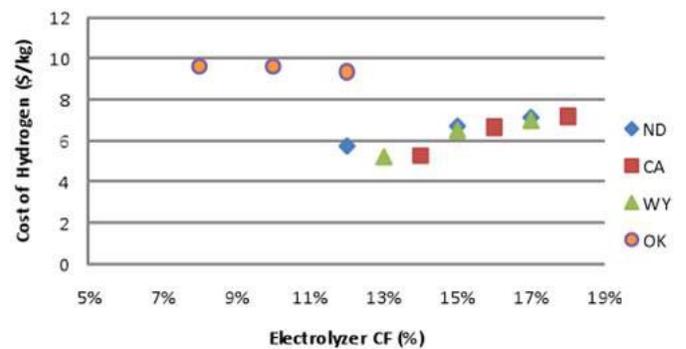

FIGURE 3. Economic Analysis for use of Otherwise Curtailed Wind for Hydrogen Production

Results

Figure 2 presents the results of adding a hydrogen energy storage system to each wind farm. The base case for each wind farm, in which some electricity is curtailed, is indicated by the red “X”s. The blue symbols show the delivered cost of electricity for the same wind farms where hydrogen energy storage has been added. In all cases, the electrolyzer has been sized to capture all the wind-generated electricity that would otherwise have been curtailed. The results indicate that the electrolyzer cost must be less than \$400/kW in most cases to make the energy storage system pay for itself.

Results of the analysis using electrolysis as a dispatchable load to produce hydrogen for the transportation sector are shown in Figure 3. The electrolyzer use was increased by diverting more of the wind farm output to the electrolyzer. Electricity in excess of what would have been curtailed must be “purchased” for electrolysis. The analysis results indicate that diverting more electricity to the electrolyzer increases the electrolyzer capacity factor and

increases the cost of the hydrogen produced for all but the Oklahoma wind farm. At the Oklahoma wind farm, the very low equipment use causes the capital cost of the electrolyzer to be the primary cost driver. In this case, increasing use, even with higher input electricity cost, reduces the resulting hydrogen cost. In all other cases, increasing the cost of electricity increases the hydrogen cost, even with better equipment use.

Conclusions and Future Directions

Increasing power generation from intermittent renewable resources will require new strategies for balancing generation and demand, including energy storage and dispatchable demand, both of which are addressed by the two hydrogen systems studied in this work. If hydrogen can play a role in addressing these needs, hydrogen will be more likely to gain a foothold as a viable alternative vehicle fuel. Two potential benefits are:

- The availability of renewable resources dedicated to hydrogen production will be limited in the near term, as these resources are being developed for electricity generation. Therefore, hydrogen must be integrated into the electricity system in such a way that it provides a service or use for excess power in addition to its value as a vehicle fuel. The strategies being analyzed in this work accomplish that objective.

- The high cost of alkaline electrolysis is primarily due to labor-intensive manufacturing methods and low production volumes. Using electrolysis to produce hydrogen, either for electricity storage or for vehicles, could increase demand to the point that more automated manufacturing methods could be used and costs would be dramatically decreased.

The analyses indicate that equipment costs, including electrolyzer costs analyzed here, must be reduced for hydrogen to be an economical alternative for energy storage or production of vehicle fuel from otherwise curtailed wind-generated electricity. However, no additional credit was taken for the various potential services that could be provided by hydrogen production, nor was any attempt made to take advantage of arbitrage opportunities.

Future work will focus on developing similar analyses for solar installations and quantifying greenhouse gas emissions and carbon tax implications, especially in comparison to compressed air energy storage.

Project End Date: October 2012

Introduction

The U.S. has wind resources to potentially produce large amounts of electricity each year. The U.S. also has significant resources of solar power, particularly in the southwestern regions of the country. These renewable sources of power are inherently intermittent and the supply of power from them cannot be controlled to match precisely the diurnal and regional demand. These renewable sources are typically curtailed when their supply becomes a large share of overall power supply, and they are supplemented with other fossil sources when their supply is less than the demand. Such intermittency imposes severe limitations on the potential large-scale utilization of renewable sources and the economics of their operation. Hydrogen has been proposed and examined in the U.S. and Europe as a potential energy storage medium to mitigate the intermittency of these renewable sources and to increase their utilization, especially with the expected large growth of these renewable sources to meet the renewable portfolio standards targets in the electric sector across the U.S. With hydrogen as a storage medium, when the incremental supply of renewable power exceeds the incremental demand, the excess power can be used to produce hydrogen for storage for later withdrawal during periods of peak power demand. Thus, hydrogen storage provides a buffer to match the supply and demand of electric power, and it could provide a significant reduction in energy use and greenhouse gas (GHG) emissions by reducing or eliminating the dependence on fossil sources that would otherwise serve the non-base (peak) load.

Argonne National Laboratory (ANL) examined the potential fuel cycle energy and emissions benefits of integrating hydrogen storage with renewable power generation. ANL also examined the fuel cycle energy use and emissions associated with alternative energy storage systems, including pumped hydro storage (PHS), compressed air energy storage (CAES), and vanadium-redox batteries (VRB). Figure 1 depicts these alternative energy storage systems for integration with grid electricity. The following sections present our approach to the above mentioned analysis, as well as the important stages, results, and key issues associated with the hydrogen use in energy storage applications.

Approach

The fuel-cycle analysis of energy storage systems depends mainly on the round-trip efficiency of each alternative storage system. The round-trip efficiency is defined as the amount of electricity produced by the energy storage system per unit electric energy input to the storage system. Table 1 lists the round-trip efficiency for the different energy storage systems considered in this analysis.

Fiscal Year (FY) 2011 Objectives

Conduct life-cycle analysis of hydrogen as energy storage for integration of large renewable generation sources into the electric grid.

Technical Barriers

This project addresses the following technical barriers from the Systems Analysis section (4.5) of the Fuel Cell Technologies Program Multi-Year Research, Development and Demonstration Plan:

- (C) Inconsistent Data, Assumptions and Guidelines
- (D) Suite of Models and Tools
- (E) Unplanned Studies and Analysis

Contribution to Achievement of DOE Systems Analysis Milestones

This project contributes to achievement of the following DOE milestone from the Systems Analysis section of the Fuel Cell Technologies Program Multi-Year Research, Development and Demonstration Plan:

- **Milestone 11:** Complete environmental analysis of the technology environmental impacts for the hydrogen scenarios and technology readiness. (2Q 2015)

FY 2011 Accomplishments

- Conducted fuel cycle analysis of hydrogen storage and alternative energy storage options in various utility regions.

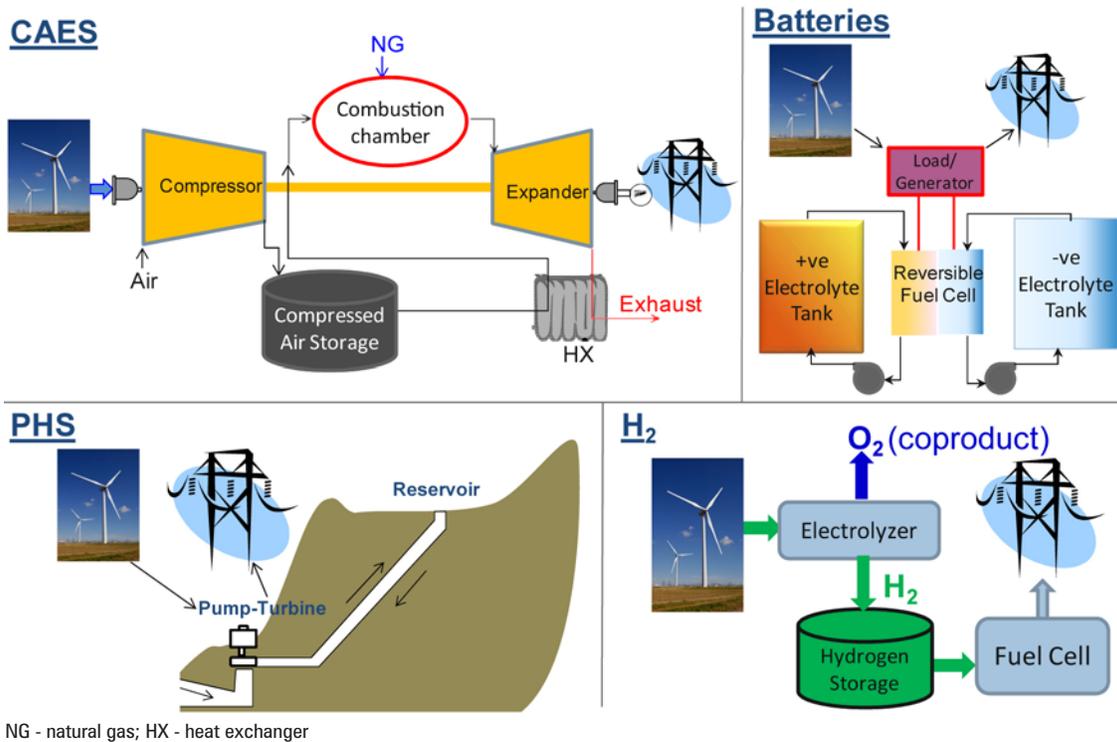

FIGURE 1. Alternative Energy Storage Systems

TABLE 1. Round-Trip Efficiency of Alternative Energy Storage Systems

Energy Storage System	Round-Trip Efficiency
Hydrogen	34%
Pumped hydro storage (PHS)	74%
Compressed air energy storage (CAES)	71%
Batteries	74%

This analysis assumes that the electricity produced from the energy storage system displaces the non-base load electricity (as provided in the eGrid database of the Environmental Protection Agency) for the different utility regions. The displacement of non-base load electricity provides an improved estimate over the displacement of fossil-based electricity generation when calculating the emission reduction benefits of clean energy projects. The electricity generation displaced by the electricity produced by the energy storage system are tracked upstream to their primary fuel sources for energy use and emissions calculations. The impact of “oxygen” as a co-product of hydrogen production via electrolysis is also included in this analysis.

Results

The fuel-cycle GHG emissions benefits per kWh of electricity produced by the energy storage systems are shown in Figure 2 for the states of California, Texas, New York, and

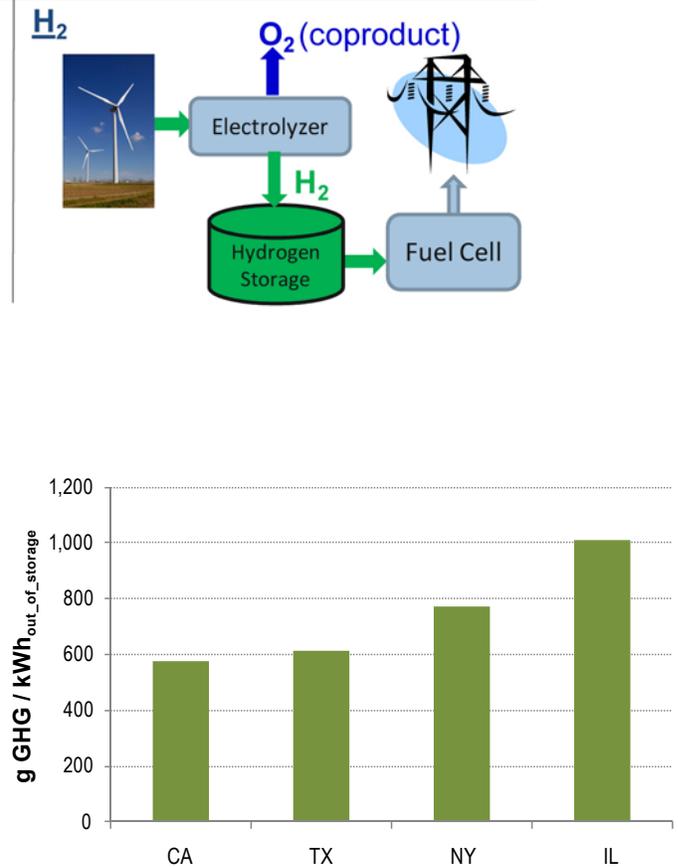

FIGURE 2. Fuel Cycle GHG Emissions Benefits of Energy Storage Systems in Different Regions (per kWh out of storage)

Illinois. Figure 2 reflects the GHG emissions saved in these regions by displacing the non-base load electricity generation units with energy produced from the storage of renewable electricity. Figure 3 shows the additional GHG savings due to the co-production of oxygen (O₂) via electrolysis using the hydrogen energy storage system. The byproduct oxygen is a high value product with high purity (>99%) that is widely used in medical facilities, steel production, semiconductor production, wastewater treatment plants, etc. Significant amounts of oxygen are coproduced (8 kg_{O₂} for each kg_{H₂}) which can displace oxygen conventionally produced in

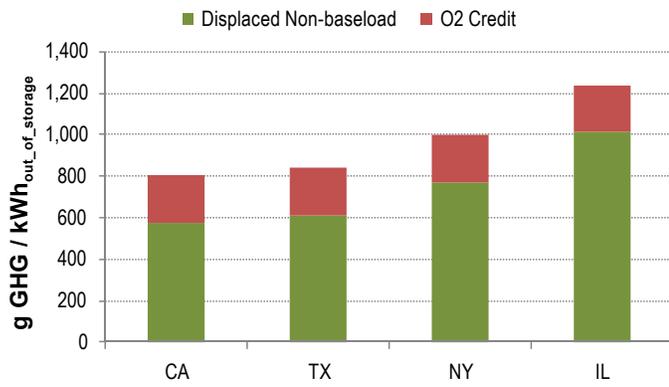

FIGURE 3. Fuel Cycle GHG Emissions Benefits of Hydrogen Energy Storage System in Different Regions (per kWh out of storage)

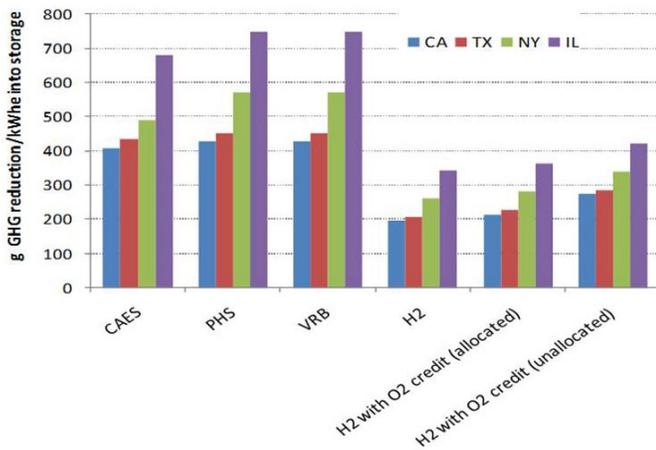

FIGURE 4. Fuel Cycle GHG Emissions Benefits of Alternative Energy Storage Systems in Different Regions (per kWh into storage)

air separation units where 0.7 kWh of electricity is used to produce 1 kg of O₂ (only 0.165 kWh/kg_{O₂} if allocating electricity use by mass with N₂). Figure 4 shows the GHG emissions benefits of the alternative energy storage systems in different regions per kWh into storage. The impact of the round-trip efficiency of the alternative energy storage systems is apparent in Figure 4, with greater GHG benefits for the storage systems associated with higher round-trip efficiency. The O₂ byproduct credit associated with the hydrogen storage system partially compensates for its low round-trip efficiency and improves its competitiveness with the other alternative storage systems.

Conclusions and Future Directions

Conclusions:

Using hydrogen for storage of electricity from renewable sources provides potential for significant reduction of GHG emissions by displacing electricity generation units that serve the non-base load in different utility regions. Energy storage systems achieve greater GHG emissions reduction when displacing more carbon intensive generation. However, the GHG emissions benefits of employing hydrogen energy storage systems are less than those associated with the alternative storage systems using CAES, PHS and batteries due to the low round-trip efficiency of the hydrogen pathway. The round-trip efficiency is crucial for life-cycle analysis of energy storage systems. Higher potential for GHG emissions reduction can be realized as the round-trip efficiency increases. The O₂ byproduct credit associated with hydrogen storage system improves its competitiveness with alternative storage systems. The emissions benefits of alternative energy storage systems should be evaluated in conjunction with other economical and technological aspects unique to each technology option.

Future Directions:

Expand the system boundary to include the energy and emissions associated with the construction of the storage facilities in the life-cycle analysis of alternative energy storage systems.

Contribution to Achievement of DOE Systems Analysis Milestones

This project will contribute to achievement of the following DOE milestones from the System Analysis and System Integration sections of the Fuel Cell Technologies Program Multi-Year Research, Development and Demonstration Plan:

- Milestone 8 (System Analysis) – Complete analysis and studies of resource/feedstock, production/delivery and existing infrastructure for technology readiness (4Q, 2014).

FY 2011 Accomplishments

- Estimated the future responsiveness of market success with hydrogen FCEVs to various degrees of research and development (R&D) success.
- Estimated the rate of growth in adoption of hydrogen FCEVs in response to hydrogen retail station size and availability as well as responsiveness to station subsidies.
- Examined variations in future reliance on different production technologies in response to R&D and carbon policies, including allocation of biomass resources between electricity production (for the grid), biomass to liquids, cellulosic ethanol, and hydrogen production.
- Examined the effectiveness of a range of vehicle subsidy types, levels and FCEV prices.
- Developed 19 distinct scenarios (six reference cases, eight sensitivity cases and five policy cases) achieving a range of reductions in GHG emissions (up to 72%) and variations in oil imports (from a 12% increase to a 14% reduction) by 2050 compared to a 2005 base year for light-duty vehicles.

Fiscal Year (FY) 2011 Objectives

- Provide a comprehensive, market-based context for analyzing hydrogen scenarios.
- Use an economic framework with competition among vehicle and hydrogen production technologies.
- Analyze the impact of alternative technology outcomes (hydrogen production, fuel cell vehicles, etc.).
- Analyze the potential role and cost of policies to accelerate adoption of fuel cell electric vehicles (FCEVs).
- Demonstrate the potential contribution of FCEVs to meeting national goals of reducing greenhouse gas (GHG) emissions and oil imports.

Technical Barriers

This project addresses the following technical barriers from the Systems Analysis section of the Fuel Cell Technologies Program Multi-Year Research, Development and Demonstration Plan:

- (A) Future Market Behavior
- (B) Stove-Piped, Siloed Analytical Capability

Introduction

The National Energy Modeling System (NEMS) is used by the DOE and the Energy Information Administration (EIA) to provide an integrated economic analysis of the future U.S. energy system under a variety of scenarios [1]. We developed the NEMS-H2 model as a modification of the existing NEMS model specifically to better address the potential role of hydrogen within the context of the U.S. energy system. As an integrated energy model, NEMS-H2 can capture interactions among various fuels as hydrogen production creates demand for different feedstocks, such as natural gas or coal, and at the same time displaces

traditional vehicle fuel use (primarily petroleum, but potentially biofuels as well). In this study we analyze a variety of scenarios to illustrate how hydrogen-powered FCEVs might provide oil and greenhouse gas emission reductions and identify other impacts on the energy system. These scenarios address the following questions:

- 1) What is the relative influence of different policy options in terms of penetration of hydrogen vehicles and associated benefits, and how does this depend on technological advances?
- 2) What are the carbon emissions and oil import reduction implications of reduced fuel demand and fuel switching as a result of technological advances in different types of hydrogen production and vehicle technologies?

Approach

The Office of Energy Efficiency and Renewable Energy (EERE) uses NEMS to estimate the benefits of its portfolio of R&D and deployment programs and to perform various types of policy analyses. Although well suited for representing most of the EERE programs, the original version of NEMS had limited hydrogen analysis capability. Hydrogen technologies were represented within NEMS on the demand side with natural gas fuel cells for stationary combined heat and power and with gasoline and hydrogen fuel cells in light-duty vehicles. The only representation of hydrogen supply is natural gas reforming used to meet the internal requirements of petroleum refineries and a simple assumption regarding natural gas consumption for hydrogen fuel cell light-duty-vehicles. Therefore, one of the primary motivations for the original NEMS-H2 development was to add a representation of hydrogen pathways to NEMS to enhance its ability to estimate the benefits of the Fuel Cell Technologies Program.

The development of NEMS-H2 followed a multi-phased approach with additional features added incrementally. At this stage, the model contains the basic elements laid out in the design report, but not all of the features originally envisioned for the eventual production version have been implemented. The model has also been extended to 2050, which was essential for analysis in that the potential emergence of hydrogen as a significant source of energy supply is not anticipated until near the end of the standard NEMS time horizon of 2030 or 2035. For more detail on NEMS, see EIA's extensive NEMS documentation [1].

The major addition to the original NEMS model is a new conversion module called the Hydrogen Market Model (HMM), which takes as input from the other NEMS sub-models the prices for various fuels and the demand for hydrogen. The HMM then provides outputs of the delivered price of hydrogen for each region and market along with demand for feedstocks used in

hydrogen production. Similar to the other conversion models within NEMS for the electricity and refinery sectors, HMM is formulated as a linear programming problem, although much smaller in size.

NEMS-H2 is also modified to include more detailed geographic representation of demand, with the following explicit market segmentations: large cities (population greater than 1 million), small cities (population between 50,000 and 1,000,000), and rural markets outside city areas (populations <50,000). With these market segments captured in each of the nine census regions used in NEMS, the NEMS-H2 model includes relatively detailed spatial representations of hydrogen pathways, including 12 production methods (eight central types, one city gate, and three distributed), multiple delivery pathways, and two retail station capacities (300 and 1,500 kg per day). Pathway costs are based upon H2A Production models from NREL, and delivery costs are based upon a set of iterative runs of Argonne National Laboratory's H2A Delivery Scenario Analysis Model (HDSAM). Though dynamic and more geographically explicit delivery costs have been developed using NREL's Scenario Evaluation and Regionalization Assessment model, the present version of NEMS-H2 relies upon delivery costs from HDSAM.

Results

Given that NEMS-H2 models the entire U.S. energy economy, a wide range of results have been collected through the development of 19 distinct scenarios. Some of the highlights are summarized in the following.

- In the carbon reference case, where significant carbon policies are adopted across the economy, FCEVs achieve 10 percent light-duty vehicle (LDV) market share by 2030 and approach 70 percent by 2050 if all R&D goals are met. In the 50% R&D success case, market share is very small before 2045 and just over 20 percent by 2050. Figure 1 indicates the on-road LDV stock associated with meeting R&D goals in the carbon reference case.

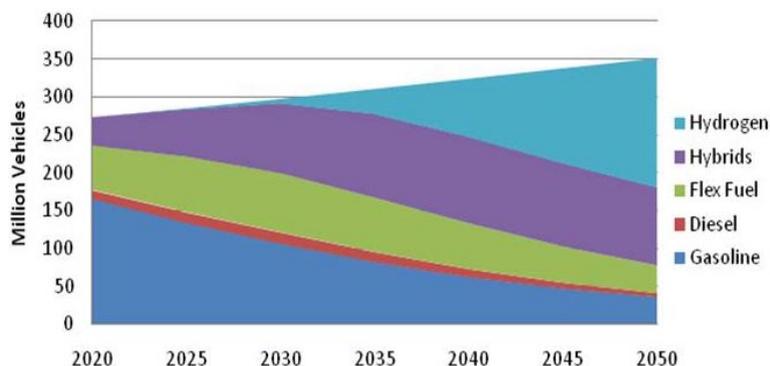

FIGURE 1. Light-Duty Vehicle Stock in the Carbon Policy Reference Case with FCEV R&D Success

- Introducing smaller stations results in greater station availability, accelerating consumer adoption (which is otherwise dampened by a lack of stations). Figure 2 indicates the influence of including small stations (300 kg/day) in NEMS-H2 in the carbon reference case, as opposed to only including large stations (1,500 kg/day).
- Sources of hydrogen are highly sensitive to carbon policy. With no carbon policy, onsite steam methane reforming and central coal gasification without sequestration are the dominant least-cost pathways, while strong carbon policy shifts production to central biomass with sequestration and coal with sequestration.

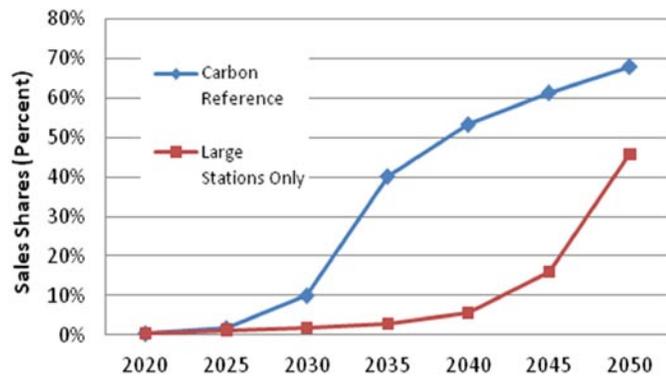

FIGURE 2. Influence of Including Smaller Stations in the Carbon Reference Case

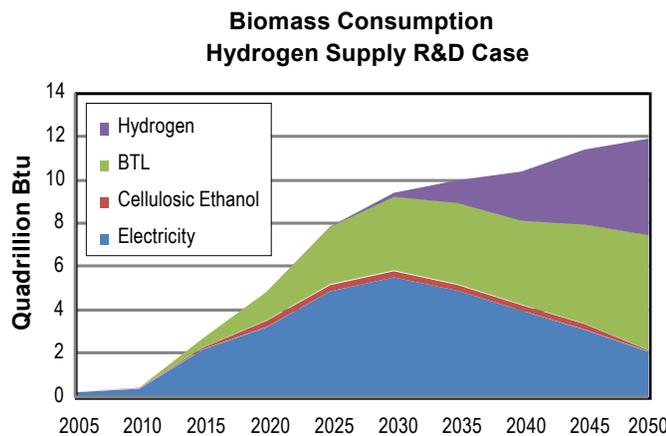

FIGURE 3. Biomass Supply and Products in the Production R&D Success Scenario

- Vehicle subsidies can be relatively effective (ranging from \$7–\$70/ton CO₂ reduced), but their effectiveness is highly dependent upon successful R&D.
- Significant use of biomass in hydrogen production could be realized if production and delivery R&D goals are met. Figure 3 shows the trend for growing biomass use in electricity, shifting toward liquid fuels around 2020, and then to hydrogen after 2030.

Conclusions and Future Directions

Our analysis has estimated the potential role of hydrogen FCEVs in the U.S. energy system using a modified version of the NEMS. The new model, NEMS-H2, estimates market share adoption and reductions in greenhouse gas emissions and petroleum consumption as a result of adopting FCEVs in the light-duty vehicle sector. We developed 19 distinct scenarios to examine important market dynamics, sector and technology interactions, R&D effects and policy strategies. Among these various scenarios, GHG emissions were reduced across a range of 16–72 percent by 2050 relative to 2005, while petroleum consumption increased in cases where FCEVs were not successful and was reduced by as much as 18 percent where they were successful. Other notable results include the importance of smaller stations in stimulating market growth, the sensitivity of hydrogen production sources to carbon policy, and the dependence of vehicle subsidy effectiveness on continued R&D progress.

Project Start Date: October 2002
Project End Date: Project continuation is
determined annually in consultation with DOE

Objectives

- Conduct fuel-cycle analysis of early market applications of fuel cell (FC) systems (to help development of hydrogen production and FC technologies).
- Evaluate environmental benefits of renewable hydrogen production pathways.
- Conduct well-to-wheels (WTW) analysis of hydrogen fuel cell vehicles (FCVs) with various hydrogen production pathways.
- Conduct vehicle-cycle analysis of hydrogen FCVs.
- Provide life-cycle results for DOE's Fuel Cell Technologies (FCT) Program activities such as the Multi-Year Research, Development, and Demonstration Plan.
- Engage in discussions and dissemination of energy and environmental benefits of FC systems and applications.

Technical Barriers

This project addresses the following technical barriers from section 4.5 of the Fuel Cell Technologies Program Multi-Year Research, Development and Demonstration Plan:

- (C) Inconsistent Data, Assumptions, and Guidelines
- (D) Suite of Models and Tools
- (E) Unplanned studies and analysis

Contribution to Achievement of DOE Systems Analysis Milestones

This project contributes to achievement of the following DOE milestone from the Systems Analysis section of the Fuel Cell Technologies Program Multi-Year Research, Development and Demonstration Plan:

- Milestone 11: Complete environmental analysis of the technology environmental impacts for the hydrogen scenarios and technology readiness. (2Q 2015)

Accomplishments

- Expanded the fuel-cycle analysis of renewable feedstock options for hydrogen production to include renewable natural gas (RNG) from landfill gas (LFG) and anaerobic digestion (AD) of animal waste.
- Conducted energy use and greenhouse gas (GHG) emissions analysis of FC systems for combined heat and power (CHP) and combined heat, hydrogen, and power (CHHP) generation using conventional natural gas (NG) and RNG.
- Evaluated the WTW energy and emissions benefits of FCVs powered by hydrogen from RNG.
- Conducted vehicle-cycle analysis of FCVs relative to conventional gasoline internal combustion engine (ICE) vehicles and gasoline hybrid electric vehicles (HEVs).
- Supported the collaborative effort of DOE's FCT Program and Vehicle Technologies Program (VTP) in updating DOE's WTW record for alternative fuel/vehicle systems, including FCVs and plug-in hybrid electric vehicles (PHEVs) [1].

Introduction

The stages included in life-cycle analysis (LCA) are raw material acquisition, transportation and processing and product manufacturing, distribution, use and disposal or recycling. LCA of a fuel is called fuel-cycle analysis, while LCA of a vehicle is called vehicle-cycle analysis. A fuel cycle is also known as a WTW cycle when the fuel is used in transportation applications (vehicles). Combining WTW results with the vehicle-cycle energy use and emissions facilitates the comparison of alternative fuel/vehicle systems on a common (life-cycle) basis. Argonne examined fuel-cycle energy use and emissions associated with the use of RNG in stationary fuel cell applications. Argonne also conducted WTW analysis of hydrogen FCVs, including alternative feedstock sources for hydrogen production. To complete the LCA of hydrogen FCVs, Argonne evaluated the vehicle-cycle energy use and emissions associated with manufacturing FCVs and compared them to those of the manufacturing of gasoline ICEVs and HEVs.

Recovered methane (CH₄) gas from landfills or from AD originates from a renewable resource and is thus considered renewable energy. Because it is chemically identical to fossil natural gas yet produces far fewer GHG emissions,

this RNG can power stationary fuel cells to produce heat and power with the option of co-producing hydrogen while providing significant GHG emissions benefits. According to Environmental Protection Agency, over 190 million metric tonnes (MMT) of CO₂-equivalent (CO₂e) emissions came from landfills, animal manure and wastewater treatment facilities in 2009, while another 98 MMT and 16 MMT were avoided by landfill gas-to-energy and manure biogas recovery projects, respectively [2,3]. By avoiding the release of methane and instead recovering and using it in stationary applications or to produce transportation fuels, large reductions in GHG emissions can be realized relative to petroleum gasoline. In the CHHP application, the excess hydrogen may be stored and used for the refueling of fuel cells powering material handling equipment (i.e., forklifts) or for the generation of supplemental electricity to satisfy the electric load during peak demand periods. The availability of a hydrogen co-product can also overcome one of the barriers to introducing hydrogen FCVs to some early FCV market places by facilitating a distributed source of hydrogen while effectively employing the primary energy source and the initial capital investment of the fuel cell to serve a facility's demand for electric and heat energy. In a mature FCV market, renewable hydrogen can be produced via steam methane reforming (SMR) of RNG to satisfy the demand for the hydrogen fuel in that market. This is especially important in places such as California where regulations require 33% of the hydrogen produced for use as fuel to come from renewable sources [4].

Approach

This study examines the fuel cycle of landfill gas and animal waste conversion to RNG, and the subsequent conversion of RNG to hydrogen fuel for FCVs. To assess the environmental benefits of RNG, we account for energy use and emissions in the reference case (or base case) and for those associated with the recovery and conversion of the renewable feed to RNG. Since the reference case consumes energy and generates emissions (in the absence of conversion to RNG), the net emissions associated with producing RNG are calculated by subtracting the reference case emissions from those emitted in the conversion process to RNG. The conversion processes of landfill gas and animal waste to RNG are described in details elsewhere [5,6].

The energy use and emissions associated with the use of RNG in stationary fuel cells for CHP and CHHP generation, and the slate of the co-products depend mainly on the efficiency of the integrated internal reformer. The individual conversion efficiencies to produce electricity, heat and hydrogen are extracted from the H2A power model developed by the National Renewable Energy Laboratory. We use the displacement approach to compare the generation of electricity and hydrogen among the different feedstock sources, and to calculate credits for the byproduct heat. The system boundary for this approach includes the fuel cell system and assumes full utilization of byproduct

heat. The energy use and emissions for this approach are evaluated per one million Btu of net electricity and hydrogen generation. The credit of byproduct heat is calculated from the displacement of equivalent amount of heat from a typical standalone heating system. The displaced heat is assumed to be produced from a NG-fired heater with 90% efficiency. Hydrogen produced from RNG for FCV applications assumes 72% efficiency for the SMR conversion process. The WTW results of the alternative fuels and vehicle systems in this report are presented in per-mile basis as well as per-kg of hydrogen equivalent basis.

Results

The fuel-cycle GHG emissions for molten carbon fuel cell (MCFC) CHP and CHHP systems are shown in Figure 1. Employing RNG in CHP and CHHP fuel cell applications achieve 78-79% GHG emissions reduction relative to conventional NG-powered fuel cells. This large reduction in GHG emissions incorporates the impact of a 2% methane leakage rate assumed for the processing of RNG. Without accounting for such leakage, the reduction in GHG emissions for RNG pathways would be 96% relative to fuel cells powered with conventional NG. The GHG emissions credit due to the displacement of conventional heat with the byproduct heat is implied in Figure 1 for each of the investigated feedstock sources.

Figure 2 shows the WTW GHG emissions of various hydrogen production pathways, including the hydrogen use in FCVs. While hydrogen produced from renewable wind power sources for use in FCVs provides the largest reduction in GHG emissions (92%) relative to gasoline ICE vehicles, hydrogen produced from RNG provides the next largest reduction in GHG emissions (85%) relative to gasoline ICE vehicles. The corresponding reduction in GHG emissions for biomass, coal with carbon capture and sequestration (w/CCS), coal without carbon capture and sequestration (w/o CCS), coke oven gas, and conventional natural gas feedstock sources are 81%, 76%, 8%, 71%, and 45%, respectively. The conversion of gasoline consumption in an ICE vehicle to per-kg of hydrogen equivalent in Figure 2 employs an energy equivalency ratio (EER)¹ of 2.3 as adopted from California Air Resources Board's Low Carbon Fuel Standard [7]. The WTW GHG emissions per mile for the alternative feedstock sources for hydrogen production and use in FCVs are presented in Figure 3. The GHG emissions for hydrogen FCVs occur entirely in the well-to-pump (WTP) activities of hydrogen production, compression, and transportation, while the majority of GHG emissions for the baseline gasoline ICE vehicle occur in the pump-to-wheels (PTW) stage (i.e., during vehicle operation). To compare FCVs with baseline gasoline ICE vehicles on a life-cycle basis, we evaluated the vehicle cycle energy use and emissions associated with manufacturing FCVs and compared it to the manufacturing of gasoline ICEVs and

¹ EER = miles per unit energy of hydrogen used in a FCV/miles per unit energy of gasoline used in an ICEV.

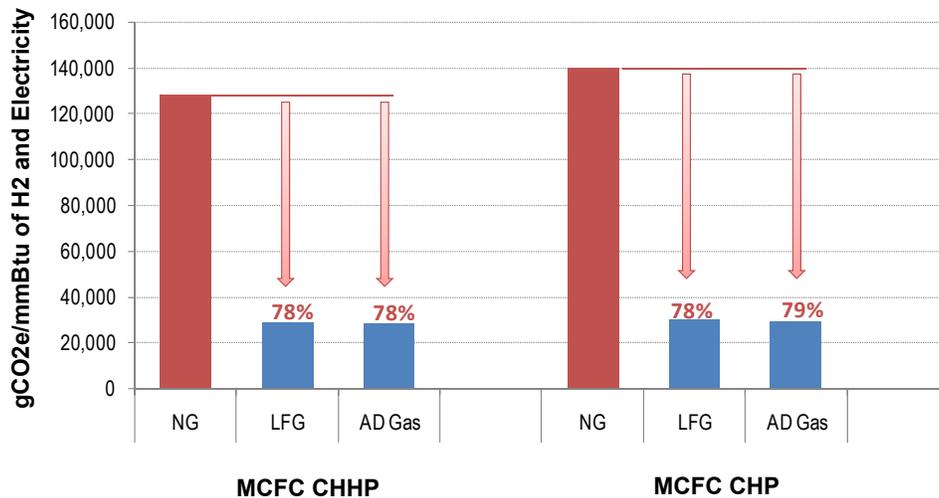

FIGURE 1. Fuel Cycle GHG Emissions from Conventional and Renewable Natural Gas Use in Stationary Fuel Cell Applications

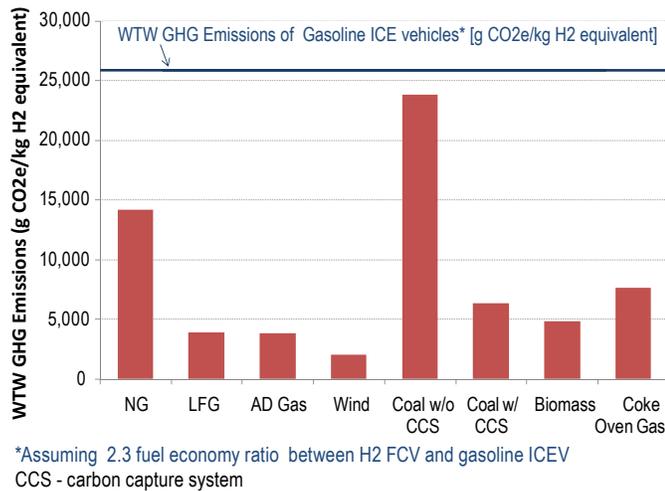

FIGURE 2. WTW GHG Emissions from Alternative Feedstock Sources for Hydrogen Production and Use in FCV Applications (per-kg H₂ equivalent)

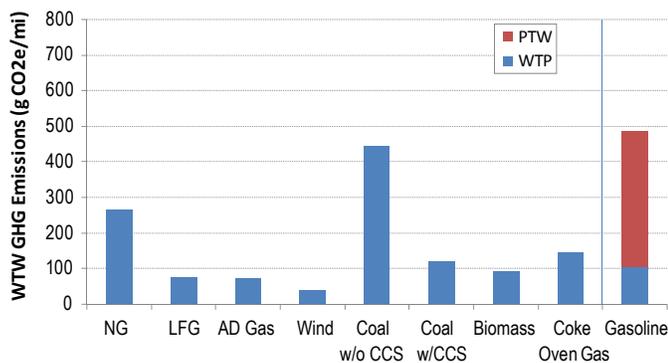

FIGURE 3. WTW GHG Emissions from Alternative Feedstock Sources for Hydrogen Production and Use in FCV Applications (per mile)

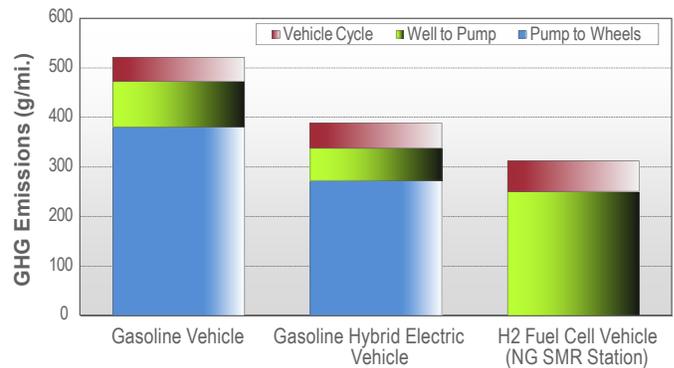

FIGURE 4. Comparison of Vehicle Cycle GHG Emissions of Hydrogen FCVs with Gasoline ICEVs and HEVs

HEVs. Figure 4 shows that while GHG emissions associated with the manufacturing of hydrogen FCVs are larger compared to gasoline ICEVs, the combined fuel cycle and vehicle cycle GHG emissions for FCVs (using hydrogen from SMR of natural gas) are 40% lower than gasoline ICEVs.

Conclusions

Hydrogen produced from RNG sources can achieve significant reductions in GHG emissions:

- CHHP and CHP FC systems powered by RNG achieve 78-79% GHG reduction relative to those powered by conventional NG.
- FCVs with hydrogen produced from RNG achieve WTW GHG reduction by:
 - 73% relative to FCVs with hydrogen produced from conventional NG.
 - 85% relative to gasoline ICEVs.

- On a vehicle-cycle basis, manufacturing FCVs require more energy and generate more GHG emissions compared to gasoline ICEVs, but FCVs reduce energy and emissions on a life-cycle basis (i.e., combined vehicle and fuel cycles).

Future Work

- Examine alternative feedstock sources for renewable hydrogen production such as waste water treatment plants.

Contribution to Achievement of DOE Systems Analysis Milestones

This project will contribute to achievement of the following DOE milestones from the System Analysis section of the Fuel Cell Technologies Program Multi-Year Research, Development and Demonstration Plan:

- **Milestone 5:** Complete analysis and studies of resource/feedstock, production/delivery and existing infrastructure for various hydrogen scenarios. (4Q, 2009)
- **Milestone 27:** Complete the 2nd version of the Macro-System Model to include the analytical capabilities to evaluate the electrical infrastructure. (2Q, 2011)

FY 2011 Accomplishments

- Completed Version 1.3 of the MSM and used it for programmatic analysis.
- Created, and (later) updated the MSM User Guide (version 1.3.2).
- Linked H2A Production cases with the Hydrogen Delivery Scenario Analysis Model (HDSAM), the Greenhouse Gases, Regulated Emissions, and Energy Use in Transportation (GREET) Model, and physical property information from the Hydrogen Analysis Resource Center (HyARC) and validated the use of those models and the results generated using them.
- Enhanced the Web-based user interface so that many members of the analysis community can use the MSM.
- Added stochastic (Monte Carlo) capabilities to the MSM.
- Upgraded the MSM to the latest versions of H2A Production (V.2.1.1-3), HDSAM (V 2.2) and GREET (V 1.8d.1).
- Linked with geospatial model HyDRA to add the spatial dimension to the MSM.
- Linked MSM with the temporal pathway evolution assessment tool HyPro.
- Linked the MSM with vehicle cycle analysis model GREET 2.7.
- Linked the Fuel Cell Power Model (FC Power) in the MSM framework.

Introduction

At the DOE Fuel Cell Technologies Program's behest, we are developing an MSM to analyze cross-cutting issues because no existing model sufficiently simulates the entire system, including feedstock, conversion, infrastructure, and vehicles, with the necessary level of technical detail. In

Fiscal Year (FY) 2011 Objectives

- Develop a macro-system model (MSM):
 - aimed at performing rapid cross-cutting analysis
 - utilizing and linking other models
 - improving consistency between models
- Support decisions regarding programmatic investments through analyses and sensitivity runs.
- Support estimates of program outputs and outcomes.

Technical Barriers

This project addresses the following technical barriers from the Systems Analysis section (4.0) of the Fuel Cell Technologies Program Multi-Year Research, Development and Demonstration Plan:

- (A) Future Market Behavior
- (B) Stove-Piped/Siloed Analytical Capability
- (C) Inconsistent Data, Assumptions and Guidelines
- (D) Suite of Models and Tools

addition, development of the MSM exposes inconsistencies in methodologies and assumptions between different component models so that they can be identified and corrected when necessary.

Version 1.0 of the MSM has been developed and is available to the hydrogen analysis community. It links H2A Production, HDSAM, GREET, and physical property information from HyARC to estimate the economics, primary energy source requirements, and emissions of multiple hydrogen production/delivery pathways. A Web-based user interface has been developed so that many users have access to the MSM; stochastic capabilities have been added to it to provide uncertainty ranges around the results. The MSM has been used for several analyses to compare pathways and to understand the effects of varying parameters on pathway results.

Approach

The MSM is being developed as a tool that links existing models across multiple platforms. This approach was chosen because the task of building a single monolithic model incorporating all of the relevant information in the existing models would have been overwhelming because the necessary expertise to do so was spread among half a dozen DOE laboratories and a dozen or more universities and private contractors. Linking models allows model users that depend on data from component models to continue using

their models while retrieving data from component models in a less labor-intensive manner. In addition, it provides a common platform for data exchange necessary to update integrated models when the component models have been updated.

The MSM is being built on a framework inspired by an example of the federated object model (FOM). FOMs also link together models and are exemplified by the Department of Defense high level architecture (HLA) [1]. The general MSM framework provides a common interlingua that is extensible (accommodates new models with a minimum of difficulty), distributable (can be used by multiple people in different areas of the country), and scalable (to large numbers of participating models). Version 1.0 of the MSM uses Ruby and Ruby interfaces to Microsoft Excel and other platforms to collect, transfer, and calculate data.

Results

Levelized hydrogen costs, primary energy requirements, and emissions have been estimated for multiple pathways using H2A V2.1 [2], HDSAM V2.2 [3], and GREET V1.8d.1 [4]. Within the MSM, hydrogen production and other costs [5] are connected with associated emissions, which is one of the advantages that the MSM provides by linking together different models. Figure 1 shows the levelized hydrogen fuel cost per mile and the well-to-wheels (WTW) greenhouse gas (GHG) emissions for each of the seven pathways assessed

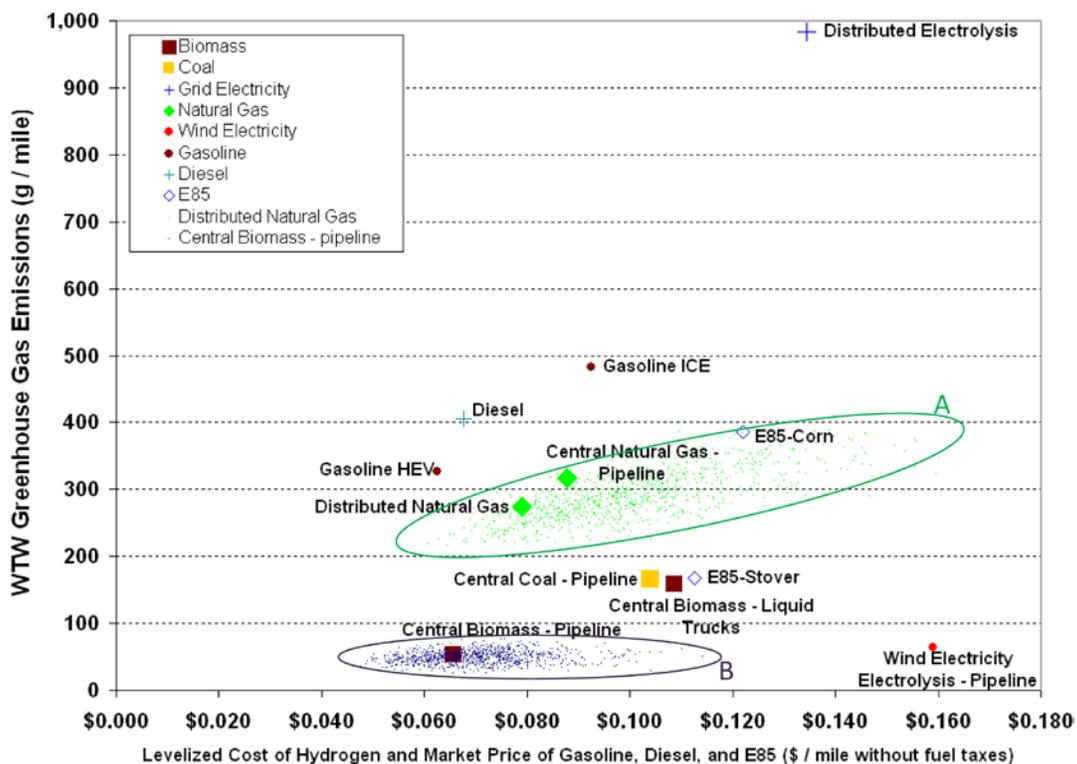

FIGURE 1. Pathways Levelized Costs and GHG Emissions

based on U.S. average fuel costs and fuel cycle energy requirements. For comparison, it also shows the projected 2009 market price per mile (in 2005 dollars) and GHG emissions for gasoline-, diesel-, and E85-fueled vehicles. The levelized fuel cost was put onto a per-mile basis. The projected fuel cost per mile for most of the hydrogen pathways (based on projected, mature fuel cell electric vehicle [FCEV] markets) is similar to that for gasoline in a traditional vehicle and corn ethanol as E85 fuel in a flexible-fuel internal combustion engine (ICE) vehicle. The fuel costs per mile for gasoline in a hybrid electric vehicle (HEV) and diesel in a conventional diesel ICE vehicle are lower.

The dotted green cloud in the figure (surrounded by oval A) represents the stochastic analysis results obtained based on input distributions for the forecourt SMR production option [6]. The dispersion of the data points well surpasses the differences between the central (with pipeline delivery) and distributed SMR production options. This relates to both the per-mile cost of hydrogen and the WTW GHG emissions. Similarly, the blue cloud surrounded by oval B shows the stochastic analysis result for the central biomass case. For the latter, as seen in the figure, the data point distribution is less significant when compared with the differences incurred by switching from pipeline to liquid truck delivery.

As key MSM inputs are sometimes region-specific, it is important to add the geospatial dimension into the range of the MSM features. Bilateral links with the online geospatial tool HyDRA [7] have been developed that allow the MSM user to easily apply regional electricity and natural gas (NG) feedstock data as MSM inputs and, conversely, update the HyDRA database and maps with the latest MSM version outputs.

Naturally, the user can specify input data as needed (it is not required that the inputs are region specific). As an example, Figure 2 shows the results obtained from NREL's FC Power model for a range of electricity grid mixes (ranked along the x-axis based on the level of upstream GHG emissions, the dotted line shows the average U.S. electricity

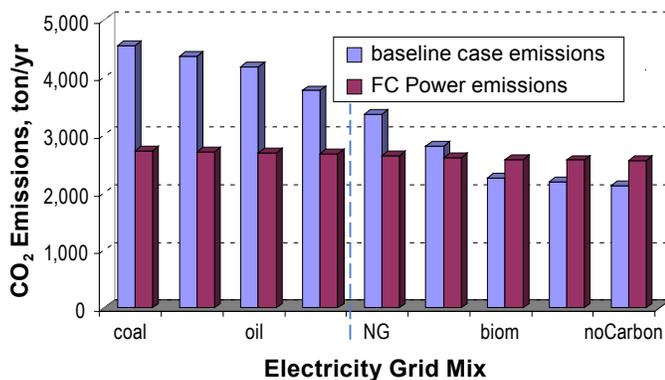

FIGURE 2. Fuel Cell Combined Heat, Hydrogen and Power Generation: Associated Emissions

generation mix upstream emissions level). Depending on the region-specific electricity generation mix, the combined heat, hydrogen, and power fuel cell generation can alleviate or aggravate the level of GHG emissions.

As a part of the ongoing enhancement of the user interface, detailed MSM outputs have been made available to the users via the Web. When combined with detailed MSM inputs access (developed earlier, in FY 2010), it makes the remote, Web-generated MSM runs almost as transparent as if the user has the MSM running on their own computer.

The transition to high-market-penetration levels for hydrogen fuel cell vehicles will likely involve several hydrogen production/delivery/dispensing pathways. To facilitate this analysis and to involve the temporal dimension, the temporal pathway evolution assessment tool HyPro [8] was developed in previous years by Directed Technologies, Inc. It is a computational model that simulates industries decisions regarding construction of new hydrogen production facilities, delivery infrastructure, and dispensing given perfect foresight of hydrogen demand. It is linked to the MSM so HyPro inputs are now updated automatically. A wide range of analysis possibilities of infrastructure evolution are now available using the MSM.

One analysis is the potential effect of a constant GHG tax on the cost-optimal succession of hydrogen production/delivery/dispensing pathways. The results of that analysis are presented in Figure 3 where the three graphs show results over a 40-year buildout scenario resulting in over 5,000,000-kg of hydrogen produced daily during the final

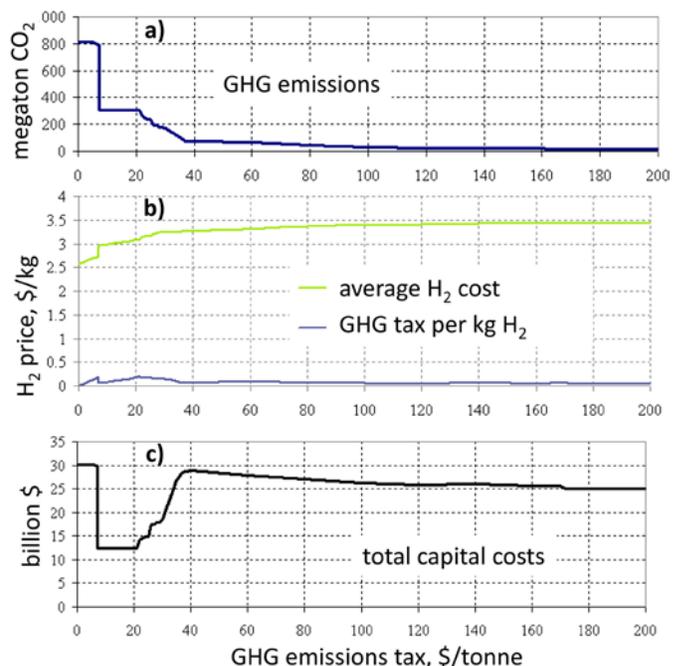

FIGURE 3. GHG Emissions Tax Effect on the Overall Emissions Level (a), Produced H₂ Costs (b) and Capital Costs (c) for a Mega-City with 12 Million Population

year. The x-axis for all graphs is a GHG emissions tax that ranges from \$0/metric tonne to \$200/metric tonne. Note that the GHG tax is held constant over each buildout scenario. Graph a shows the cumulative GHG emissions over the buildout scenario; graph b shows the average levelized hydrogen cost over the 40 years and the portion of that cost that pays for the GHG tax; graph c shows the cumulative capital investment for infrastructure over the scenario.

When the GHG tax is set to zero, forecourt SMR stations are built initially and those are replaced with central coal gasifiers without CCS and with pipeline delivery of hydrogen once the levelized cost of gasifier/pipeline hydrogen is less than the forecourt SMR cost. When the tax rate is between \$7/tonne and \$20/tonne, distributed SMR production option becomes more economical than central coal gasification throughout the 40-year buildout scenario so no coal facilities are selected. That choice results in a large decrease in GHG emissions (graph a) because SMR is less carbon intensive than coal gasification and a large decrease in capital costs (graph c) because SMR is less capital intensive. On the other hand, it causes an increase in average levelized cost because large coal facilities have a lower levelized cost than distributed SMR facilities. If the GHG emissions tax is between \$20/tonne and \$40/tonne, distributed SMR is replaced by coal gasification with CCS. At levels above \$40/tonne biomass gasification is the dominant technology. Notably, the largest effect (in terms of overall GHG emissions reduction) is achieved at relatively low tax levels. The penalty (in terms of H₂ cost increase) is significant (up to \$1/kg) but not prohibitively high. Only a small fraction of the cost increase is paid as GHG tax (the GHG tax curve on chart b) with most of the cost increase due to technology selection. Finally, higher GHG tax tends to decrease total capital costs of building the H₂ infrastructure.

Conclusions and Future Directions

- By linking production/delivery/dispensing models, the MSM is a tool for rapid cross-cutting comparative analysis of various production/delivery pathways.
- The U.S. region-specific data are readily available as MSM inputs via live MSM/HyDRA links.
- As a result of linking HyPro with the MSM, pathway evolution is examined in a manner consistent with latest versions of H2A and HDSAM.

Future Directions

- Further analyze production, delivery and distribution options, compare pathways to identify strengths of each.
- Analyze hydrogen buildout scenarios.
- Identify potential effects of not meeting targets and ensuing trade-offs.

Contribution to Achievement of DOE Systems Analysis Milestones

This project will contribute to achievement of the following DOE milestones from the System Analysis and System Integration sections of the Fuel Cell Technologies Program Multi-Year Research, Development and Demonstration Plan:

- Milestone 8 (System Analysis): Complete analysis and studies of resource/feedstock, production/delivery and existing infrastructure for technology readiness. (4Q, 2014)
- Milestone 27 (System Analysis): Complete the 2nd version of the Macro-System Model (MSM) to include the analytical capabilities to evaluate the electrical infrastructure. (2Q, 2011)
- Milestone 15 (System Integration): MSM analysis test cases. (4Q, 2006; 3Q, 2009; 4Q, 2010)

FY 2011 Accomplishments

- Interoperability has been established with other models and applications, including the Scenario Evaluation and Regionalization Analysis (SERA) model.
 - HyDRA data is now available as Web Mapping Service and Web Feature Service which can be used by any external application capable of interacting with these standards-based services.
- Attribute querying capability has been added to HyDRA.
- Basic charting of datasets in HyDRA will be completed within FY 2011.
- Interaction with the BioenergyKDF project.
 - HyDRA and the BioenergyKDF are now interoperable and capable of actively sharing data.
- The OpenEI project will leverage data to be used by HyDRA, with plans to ingest a variety of datasets to be used within HyDRA. These services should be available in FY 2012.
- Increased the number of spatial data layers related to hydrogen resource, infrastructure, and demand to over 100 layers. These datasets are comprised of background data, model input data, and results from spatial analysis and modeling activities.
- A diverse group of 257 users from 62 countries have accessed the HyDRA application in FY 2011, including university (University of Chicago, Sonoma State University, University of California, Davis), industry (Air Products and Chemicals, Inc., Apple, Matheson Tri-gas), and government agency stakeholders (Office of the Secretary of Defense, DOE)

Fiscal Year (FY) 2011 Objectives

- Develop a Web-based Geographic Information System (GIS) tool to allow analysts, decision makers, and general users to view, download, and analyze hydrogen demand, resource, and infrastructure data spatially and dynamically.
- Provide a repository for hydrogen spatial data inputs and model results.
- Display and aggregate the results of spatial analyses.
- Support interoperability between HyDRA and similar applications in other domains of energy infrastructure research.
- Expand visualization and querying of temporal and multivariate datasets.
- Extend data acquisition and ingestion capabilities.
- Enhance analysis capabilities within HyDRA.

Technical Barriers

This project addresses the following technical barriers from the Systems Analysis section of the Fuel Cell Technologies Program Multi-Year Research, Development and Demonstration Plan:

- (A) Stove-Piped/Siloed Analytical Capability
- (B) Inconsistent Data, Assumptions, and Guidelines
- (C) Suite of Models and Tools

Introduction

The HyDRA tool was developed to conduct dynamic geographic analysis of hydrogen processes in a Web-based environment. This capability is important as resource conversion, demand, and infrastructure components vary regionally for different hydrogen production, delivery, storage and retail dispensing systems. HyDRA provides a repository for storing spatial data used by hydrogen analyses and tools, and allows analysis results from multiple domains of research to be explored and compared from within a single interface.

Approach

The HyDRA tool is a state-of-the-art, Web 2.0 application that has the look, feel, and functionality of a traditional client-based GIS application. It provides the capability to view hydrogen data and how they vary across the United States on a regional basis. HyDRA provides analysis results in the form of maps that can be queried to access the numbers behind the visualization. It is available at <http://maps.nrel.gov>. Users can view spatial hydrogen data and interact with the maps to create custom analyses. Data can be downloaded from the application and used in other analyses. To ensure HyDRA's usability, NREL

recently redesigned it from its original code base to provide an easier to use, more intuitive interface. Users will be able to create their own spatial datasets and upload them into the HyDRA application to create a completely customizable and dynamic analysis tool.

The capability to explore and query spatial data layers is a core capability of the HyDRA application. There are currently more than 100 datasets available in the system including resource cost and availability, hydrogen production potential, hydrogen production cost, resource consumption, hydrogen demand, infrastructure, and results from integration with other hydrogen models. The ability to access externally hosted datasets, and also to run the MSM from within HyDRA, will provide access to a significant number of datasets and analysis results. Additionally, dynamic data acquisition services will provide up to date versions of data that change over time.

Results

The major HyDRA efforts that have been accomplished this year involve interoperability, data querying, and visualization. HyDRA is now capable of full interoperability with other standards-based geospatial data systems and is sharing datasets with the BioenergyKDF. This capability will also allow HyDRA to share data with SERA, MSM, and any other modeling, analysis, or data exploration application that can use standards-based data (Figures 1 and 2).

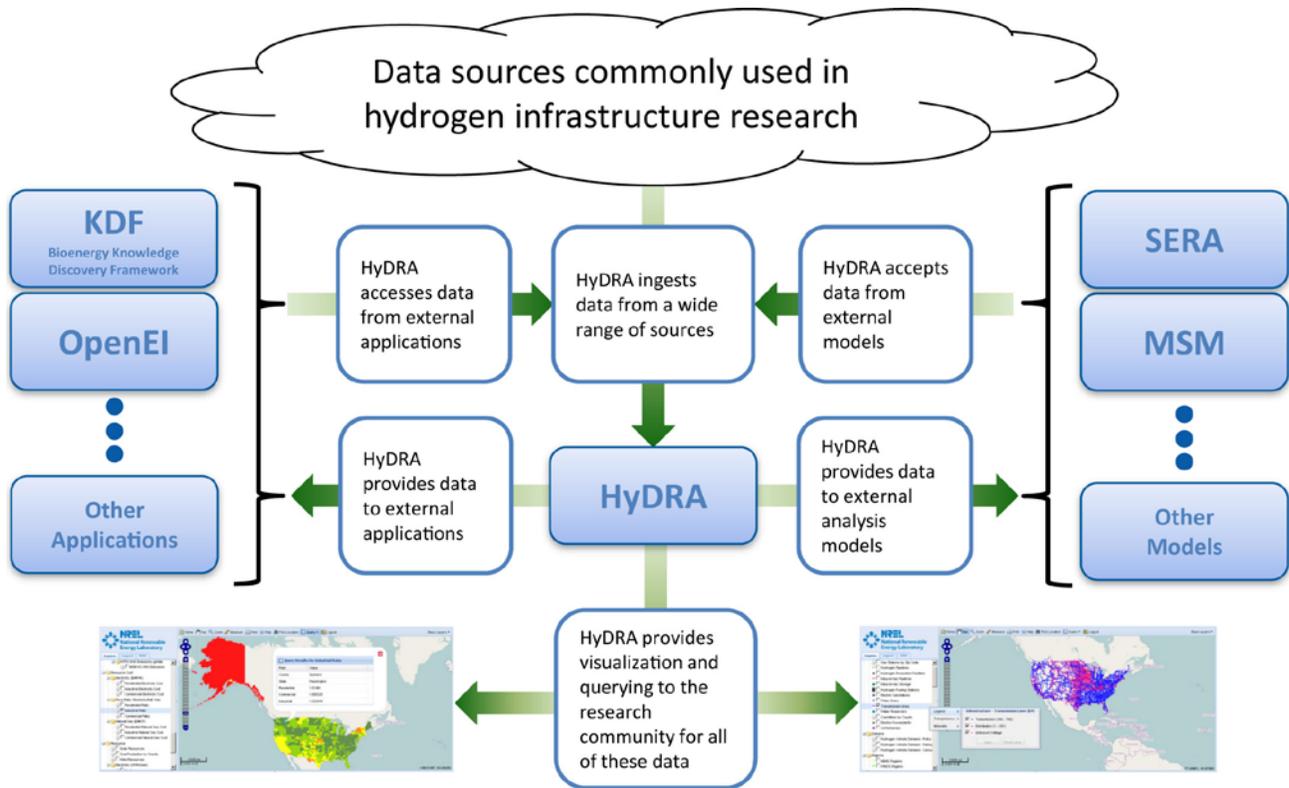

FIGURE 1. Interoperability Between HyDRA and Other DOE-Funded Applications And Modeling Efforts

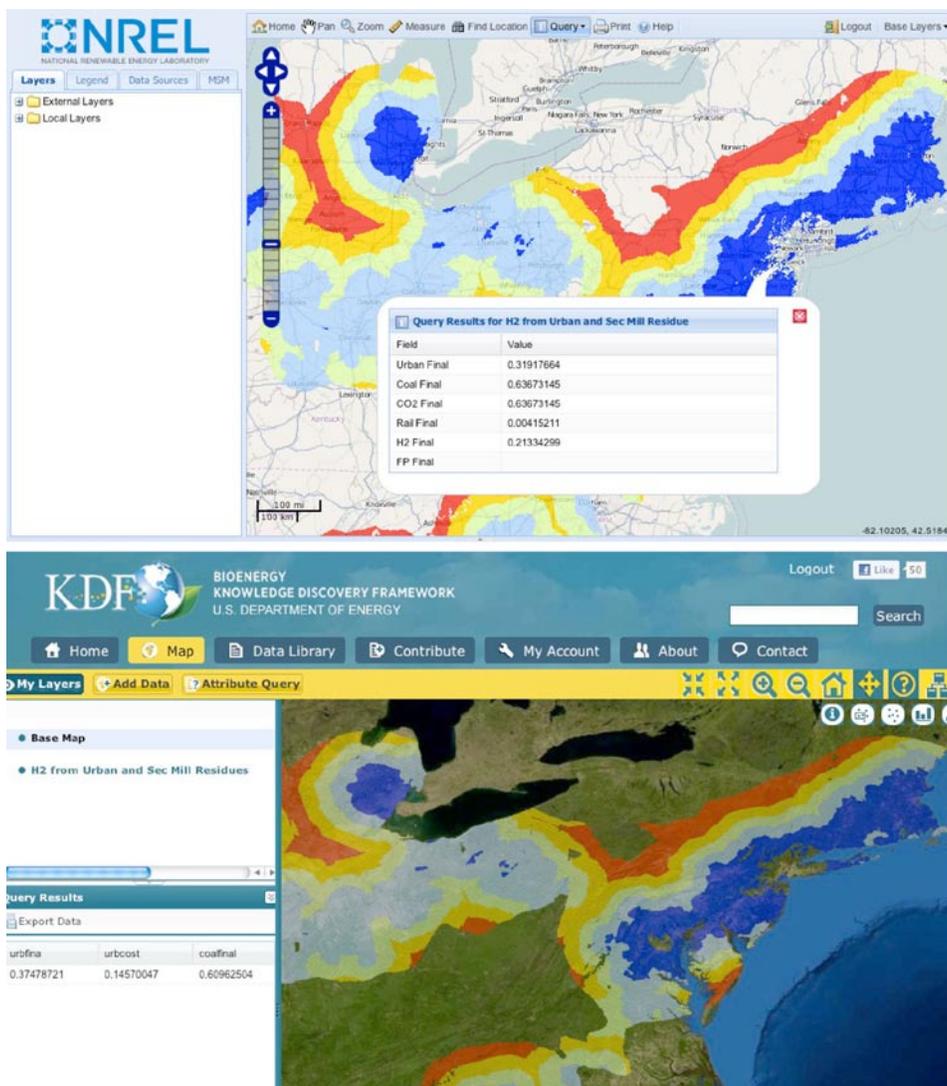

FIGURE 2. Data Stored in HyDRA and Accessed in both HyDRA and the BioenergyKDF

An advanced attribute querying capability has been implemented in HyDRA. For any layer within HyDRA the user can select multiple attributes to build a complex query and then run that query in the interface to select features that meet specific parameters. This capability will allow users to ask complicated questions about data within the HyDRA application and to explore research results in a more sophisticated manner than was previously possible (Figure 3).

In an effort to provide users with another path to visualize research data within HyDRA, a first level charting capability is being implemented in FY 2011. For any layer within the HyDRA application, users can specify up to four attributes to chart from the dataset. In combination with the spatial display and new querying capabilities, this elevates the potential to use HyDRA for analysis and provides information tailored to more specific decision making activities for users (Figure 4).

Additionally, several new datasets have been ingested into HyDRA and are available for use with the new attribute query, for use in external applications, and will be available for charting by the end of FY 2011.

Conclusions and Future Directions

HyDRA provides a single point of access to spatial data related to hydrogen systems. Improvements to the user interface and functionality provide a more intuitive user experience and improved analysis capabilities. Additionally, the enhanced interoperability of HyDRA simplifies the direct use of this data in analysis and modeling activities, and places HyDRA at the center of many other applications and research efforts. In the future HyDRA will focus on the following areas:

- HyDRA as a collaboration tool:

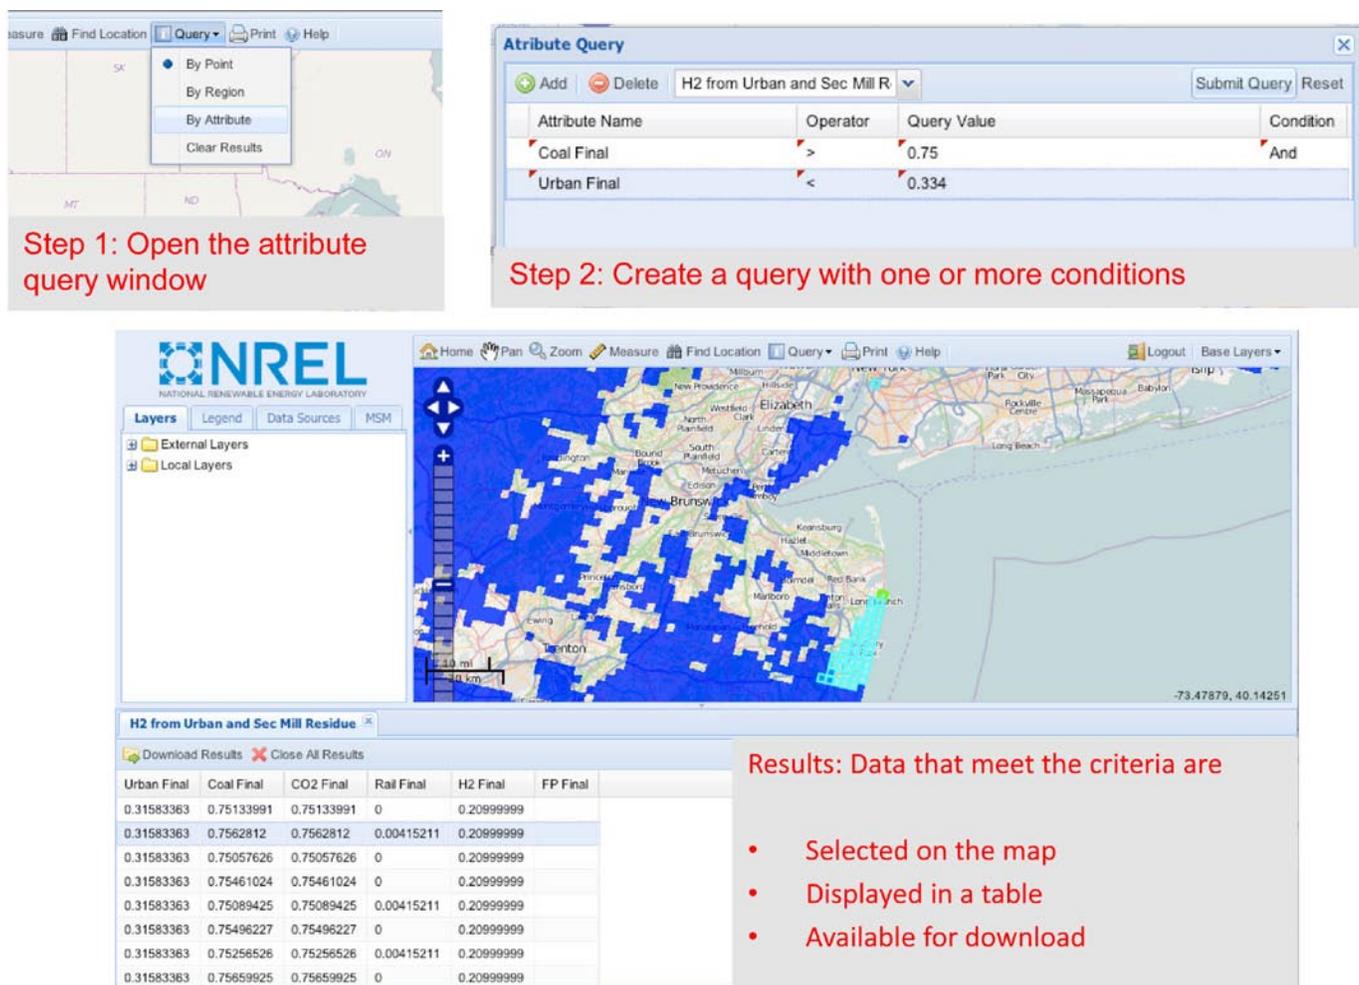

FIGURE 3. Attribute Query Example in HyDRA

- HyDRA will be used as a means of communicating spatial and temporal results from a number of future scenario studies, including wind-to-hydrogen analyses, California and other early market growth case studies, and nationwide hydrogen infrastructure rollout scenarios.
- Coordination with OpenEI will result in the development a process for automatically updating some datasets in the HyDRA application on a regular basis.
- Continue to integrate with other hydrogen models and analyses to develop new data input layers and to display model results using both manual and dynamic data integration.
- Allow for simple hydrogen system cost calculations through the HyDRA interface, relying upon H2A model result and assumptions.
- Formalize data interoperability relationships and data exchanges between other spatial data analysis and visualization applications in other domains of research.
- Completion of the advanced visualization tool:
 - The visualization tool that was cut this FY will be further developed in FY 2012 and focused mainly on exploring the results of NREL hydrogen systems analyses. In its final version, this visualization tool will open within HyDRA and be used to explore data from a wide range of sources, including runs of the MSM and SERA models.
- OpenCarto:
 - Develop complex querying capability, including enhanced spatial queries, to analyze temporal and multivariate datasets.
 - Collaboration with multiple projects that use OpenCarto to improve this framework and to enhance its capabilities in FY 2012 to support new geospatial technologies including advanced visualization and querying.
 - More interaction through the user interface to support communication about data availability and quality.

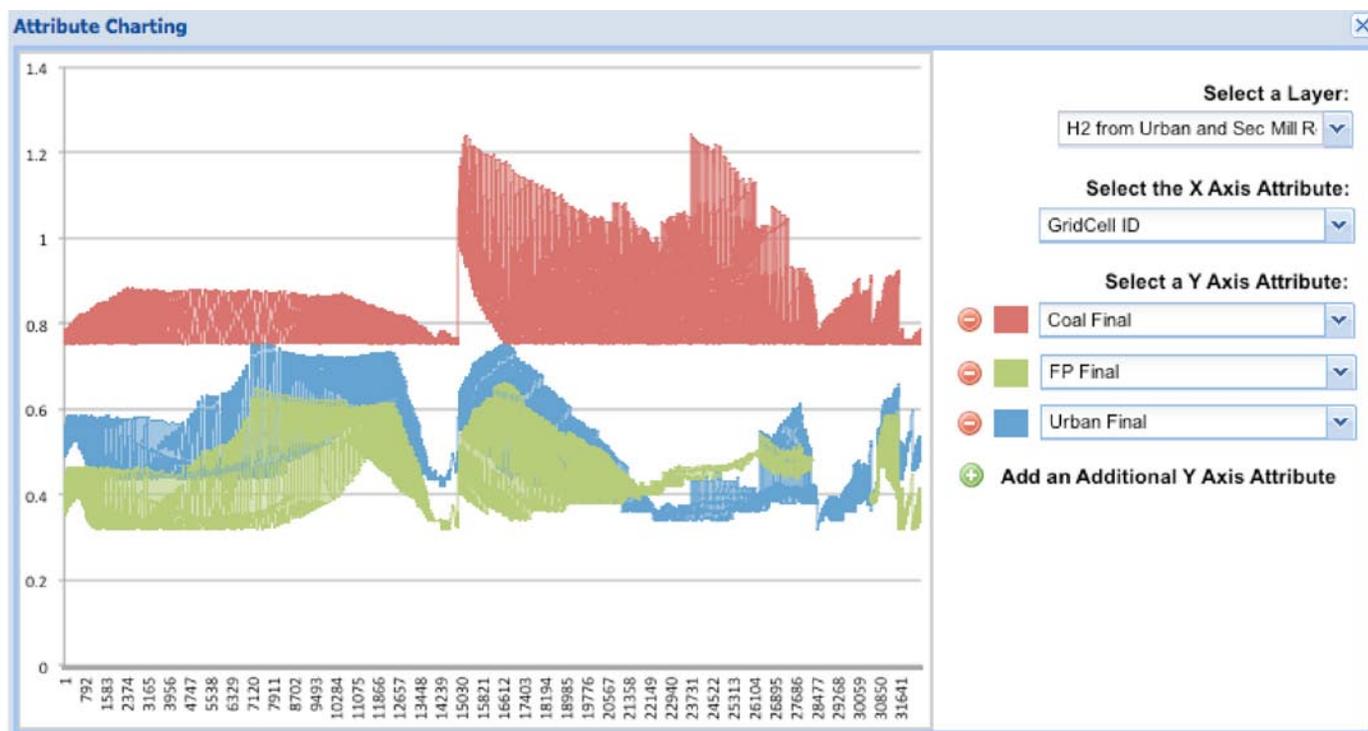

FIGURE 4. A Schematic of Layer Charting in HyDRA

- Long-term project support and data updates.
- Allow users to customize map classification and dynamically manipulate charting variables.
- Provide an interface to dynamically create, print, and export images of maps and charts.
- Continue to develop the capability to generate dynamic layers in the HyDRA application from user and model generated data.
- Develop and deploy basic analysis functions such as graphing, changing underlying assumptions, and buffering.

- **Milestone 11:** Complete environmental analysis of the technology environmental impacts for the hydrogen scenarios and technology readiness. (2Q 2015)

FY 2011 Accomplishments

- Produced an “atlas” of 51 state-level energy flowcharts (50 states plus Washington, D.C.) using automated analysis of the Energy Information Administration’s (EIA) State Energy Data System (SEDS).
- Published an “atlas” of 51 state-level carbon flowcharts (50 states plus Washington, D.C.) by combining expert analysis of EIA’s Greenhouse Gas reports with automated analysis of SEDS.
- Created an “atlas” of 52 state-level water flowcharts (50 states plus Puerto Rico and the Virgin Islands) using automated analysis of United States Geological Survey (USGS) water use and disposition data.
- Compiled an “atlas” of 136 national-level foreign country energy flowcharts using automated analysis of International Energy Agency data.

Fiscal Year (FY) 2011 Objectives

- Depict energy use at the state and international level.
- Depict water use at the state level.
- Depict carbon emissions at the state level.
- Increase the fidelity of conceptual energy depictions in the residential and transportation sectors.

Technical Barriers

This project addresses the following technical barriers from the Systems Analysis section of the Fuel Cell Technologies Program Multi-Year Research, Development and Demonstration Plan:

- (A) Future Market Behavior
- (D) Feedstock Issues
- (E) Unplanned Analyses

Contribution to Achievement Systems Analysis Milestones

This project will contribute to achievement of the following DOE milestones from the Systems Analysis section of the Fuel Cell Technologies Program Multi-Year Research, Development and Demonstration Plan:

- **Milestone 1:** Complete evaluation of the factors (geographic, resource availability, existing infrastructure) that most impact hydrogen fuel and vehicles. (3Q, 2005)
- **Milestone 5:** Complete analysis and studies of resource/feedstock, production/delivery and existing infrastructure for various hydrogen scenarios. (4Q, 2009)

Introduction

Energy informatics is the combination of expert knowledge of the energy system with data-science tools and information technology. The products of an informatics program are methodologies, tools, visualizations and reports that enable analysts and decision makers to better understand the energy system at multiple scales.

The Fuel Cell Technologies Program has enabled stakeholders to visualize critical commodity flows at geographic scales relevant to decision-makers. These commodities include energy, carbon and water. Adoption of hydrogen fuel may alter the structure of the energy system, shift or reduce the emissions of carbon dioxide, and place new demands on water infrastructure. In previous years, LLNL has analyzed the quantitative impacts of hydrogen’s potential impacts on local water systems. This year, through a campaign of energy informatics, we have provided qualitative (structural visualizations) and quantitative (energy statistics) descriptions of energy, carbon and water systems at multiple scales.

Approach

The energy flowcharts (EFCs) (<http://flowcharts.llnl.gov>) have long been recognized for their importance in visualizing energy and material flows in a way that highlights

resources, carriers, transformations and services. But, like a map of the interstate system, the published EFCs provide only a high-level view of the country’s energy infrastructure. The usefulness of this top-down view is limited by the level of detail that can be conveyed in a single image.

In order to provide a more detailed view of energy, carbon and water systems to state-level and international-level decision-makers, we have applied software tools developed here at LLNL to produce visually informative graphics from analytical reductions of publicly available statistical data sets.

Results

Although example charts are included in this report, the reader is encouraged to download each of the “atlases” of flowcharts from <http://flowcharts.llnl.gov>.

Flowcharts were produced depicting energy at the state level. This collection includes all 50 U.S. states as well as the District of Columbia, for a total of 51 charts. As an example, Figure 1 shows the energy use in the state of California. Because this report does not permit full-page figures, the reader is encouraged to download the entire “atlas” of state-level flowcharts from <http://flowcharts.llnl.gov>. The report, entitled “Estimated State-Level Energy Flows in 2008,” explains how the 30 megabyte SEDS data archive [1] is compressed to ~40 critical energy indicators for each state. In these figures, stakeholders at the state level can view their consumption of various energy resources, and visually compare the energy intensity of

various economic sectors within their states. These charts also include information on net electricity imports/exports across state lines. There are significant differences between states. For example, it is well known that Texas is one of the states with the highest overall energy use, but the flowchart depicts that much of this energy is consumed by industry. It is also easy to see Hawaii’s dependence on petroleum.

Flowcharts were produced depicting carbon emissions at the state level. This collection includes all 50 U.S. states as well as the District of Columbia, for a total of 51 charts. As an example, Figure 2 shows the carbon emissions in the state of California. Because this report does not permit full-page figures, the reader is encouraged to download the entire “atlas” of state-level flowcharts from <http://flowcharts.llnl.gov>. The report, entitled “Estimated Carbon Emissions in 2008: United States” explains how the 30 megabyte SEDS data archive [1] is compressed to ~40 critical energy indicators for each state and combined with EIA’s greenhouse gas emissions data [2,3] to determine CO₂ flows. In these figures, stakeholders at the state level can view their CO₂ emissions, and visually compare the carbon intensity of various energy-related activities within their states. For example, from these charts, it is clear that California’s CO₂ emissions are dominated by transportation, whereas Wyoming’s and West Virginia’s emissions are dominated by coal-fired electricity. A quick glance at the energy flowcharts for these two states shows that they are also major electricity exporters.

Flowcharts were produced depicting water use at the state level. This collection includes all 50 U.S. states as well

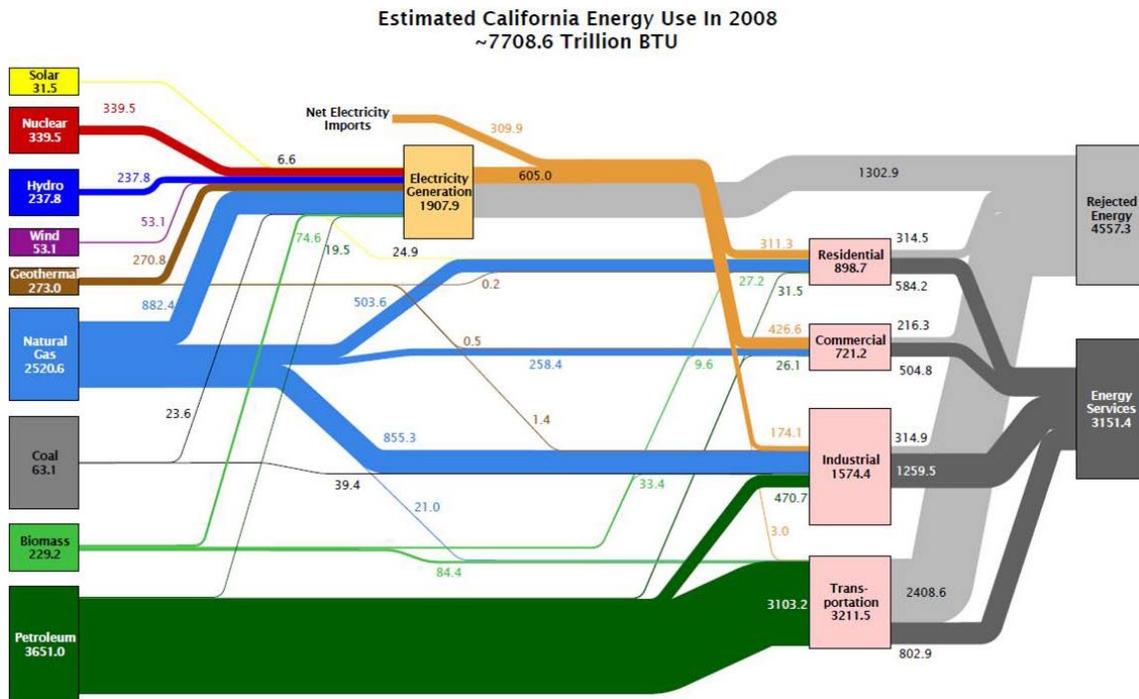

FIGURE 1. California Energy Flow in 2008

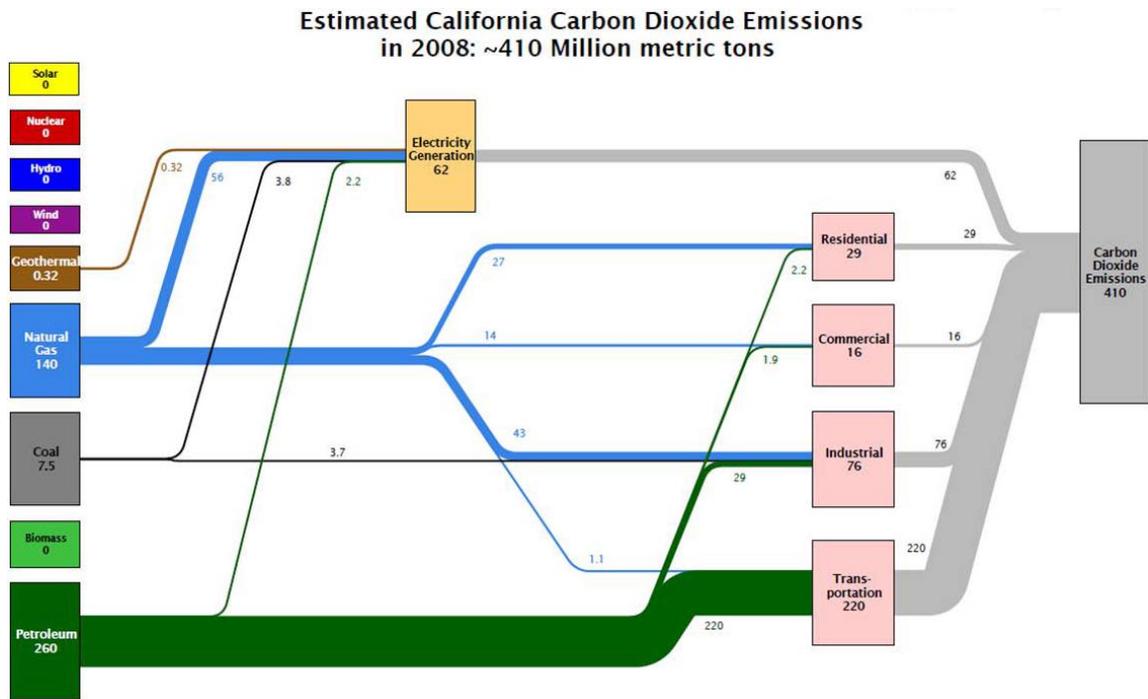

FIGURE 2. California Carbon Emissions in 2008

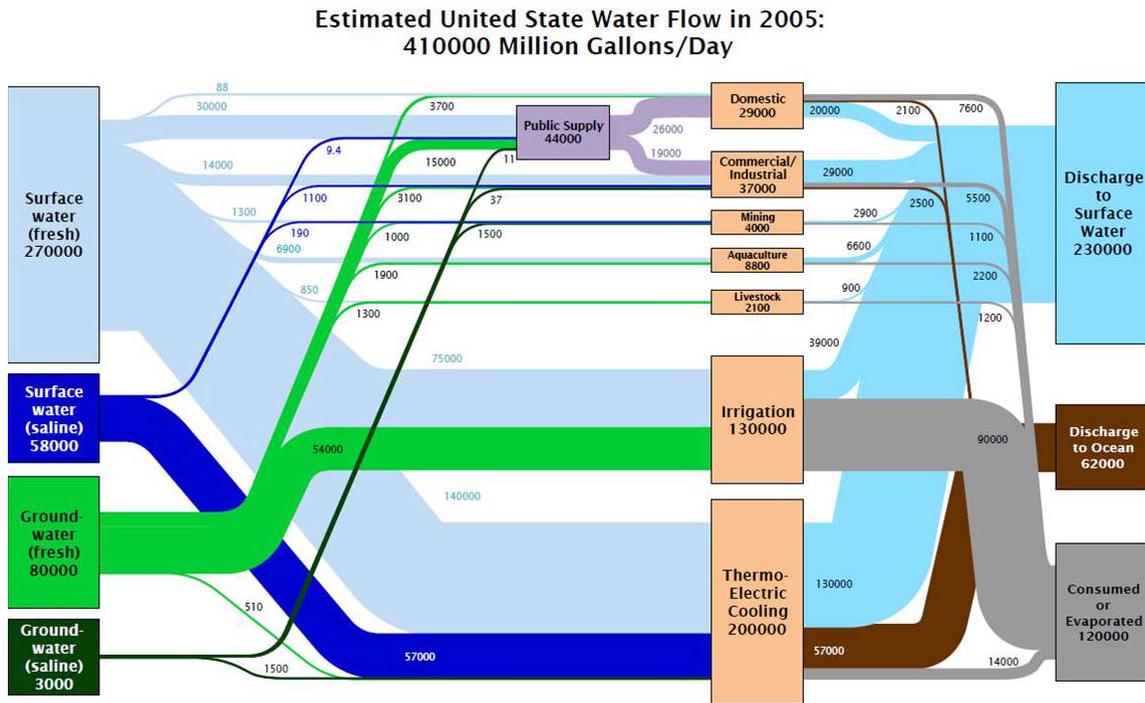

FIGURE 3. U.S. Water Flow in 2005

as the Puerto Rico and the Virgin Islands.. It also includes a composite national-level water flowchart for a total of fifty-three. As an example, Figure 3 shows the national-level water flowchart. Because this report does not permit full-page figures, the reader is encouraged to download the

entire “atlas” of state-level flowcharts from <http://flowcharts.lnl.gov>. The report, entitled “Estimated Water Flows in 2005: United States” describes how the ~300,000 county-level water statistics compiled by the USGS [4] are reduced to ~40 critical water indicators for each state. These

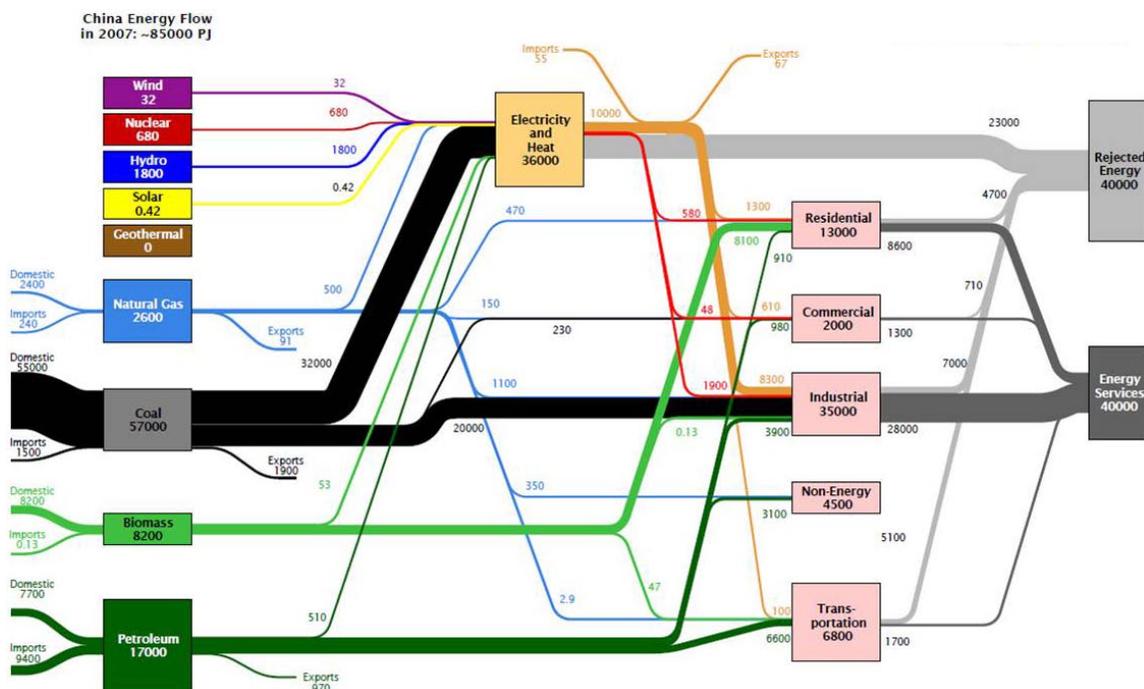

FIGURE 4. China Energy Use in 2007

figures allow a broad variety of stakeholders, including government, industrial, agricultural and environmental professionals, to quantitatively describe the structure of the water procurement, use and disposal systems. Of particular interest is the difference between western states and eastern states: managed water use in states such as Montana, New Mexico, Colorado and California tends to be dominated by irrigation, with power plant cooling as the only other water consumer at that magnitude. In the east, managed irrigation is significantly smaller due to more abundant rainfall.

One-hundred, thirty-six national-level energy flowcharts were produced depicting energy resources, use and disposition in foreign countries. This collection also includes a global-level aggregate energy flowchart for world energy use. As an example, Figure 4 shows the national-level energy flowchart for China. Because this report does not permit full-page figures, the reader is encouraged to download the entire “atlas” of state-level flowcharts from <http://flowcharts.llnl.gov>. The report, entitled “2007 Estimated International Energy Flows” describes how international energy data [5] are reduced from ~5,000 data points for each country to ~60 critical energy indicators. These figures enable visualizations of energy use patterns beyond the borders of the U.S., thereby giving stakeholders a quantitative and structural view of alternative energy infrastructures. Despite major differences between developed, transitional and developing economies, the resources, transformations and uses of energy as depicted are sufficient to capture all of the statistics. One major outlier is South Africa, whose coal liquefaction industry is large enough to warrant a separate transformation step.

Conclusions and Future Directions

Flowcharts, or “Sankey Diagrams” provide quantitative and qualitative information about flows of vital commodities within a defined geographical area or economic sector. As a result of this project, LLNL has produced flowcharts the three material flows most critical to the transformation of the energy economy.

- Decision makers now have access to a visual representation of state-level energy and carbon flows. Because environmental and technology regulations are often enforced at the state-level, these charts will empower the stakeholders closest to policy to better understand their energy use and environmental impact.
- Decision makers now have access to a visual representation of state-level water flows. Water is a fundamentally local commodity; water is used in such great quantity that the engineering of meaningful long-distance water conveyance is costly and therefore the rare exception. A quantitative and qualitative visual description of water supply, use and disposition at the state-level enables policy decisions at a geographic-scale comparable to that of many hydrologic basins.
- Decision makers now have access to a visual representation of national-level energy flows for most of the world’s nations. Clearer intuition regarding foreign countries’ energy use will enhance economic and security policymaking, as well as provide examples of alternative energy use patterns.

- Future directions of this research include visualizations of the details of energy use within the residential, transportation and industrial sectors. While we have demonstrated that flowcharts can be used to enable decision makers at finer geographic scales, we also intend to “zoom in” to finer structural details of the energy system.

E-mail: Fred.Joseck@ee.doe.gov

Project Start Date: October 1, 2006
Project End Date: Project continuation and
direction determined annually by DOE

FY 2011 Accomplishments

- A database, started in the last FY, to document the impurities encountered in stationary fuel cell systems by reviewing the literature and other public domain information has been extended to include halocarbons, volatile organic compounds (VOCs), and organosilicon compounds.
- The tolerance limits of various types of fuel cells to fuel impurities have been documented.
- A model of a stationary fuel cell-based combined heat and power system has been developed to estimate the effect of impurity levels on the cost of hydrogen:
 - Fueled by anaerobic digester gas cleaned through available technologies.
 - Power generated with a molten carbonate fuel cell.

Fiscal Year (FY) 2011 Objectives

- Study the effects of impurities on fuel cell systems for stationary applications.
- Correlate the cost of electricity to impurity concentrations in the fuel feedstock.

Technical Barriers

This project addresses the following technical barriers from the Systems Analysis section of the Fuel Cell Technologies Program Multi-Year Research, Development and Demonstration Plan:

- (B) Stove-piped/Siloed Analytical Capability
- (D) Suite of Models and Tools

Contribution to Achievement of DOE Systems Analysis Milestones

This project will contribute to achieving the following DOE Systems Analysis milestones from the Systems Analysis section of the Fuel Cell Technologies Program Multi-Year Research, Development, and Demonstration Plan:

- **Milestone 8:** Complete analysis and studies of resource/feedstock, production/delivery and existing infrastructure for technology readiness (4Q, 2014). The study described here analyzes the quality of resources/feedstocks, their conversion to reformat, and subsequent purification to meet the tolerance levels of the fuel cell stacks in stationary fuel cell systems. The analysis results in estimates of the differential cost of hydrogen attributable to gas clean-up.

Introduction

Fuel cell systems are being deployed in stationary applications for the generation of electricity, heat, and hydrogen. These systems use a variety of fuel cell types, ranging from the low temperature polymer electrolyte fuel cell (PEFC) to the high temperature solid oxide fuel cell (SOFC). Depending on the application and location, these systems are being designed to operate on reformat or syngas produced from various fuels that include natural gas, biogas, coal gas, etc. All of these fuels contain species that can potentially damage or pose a hazard for the fuel cell anode or other unit operations and processes that precede the fuel cell. These effects include loss in performance or durability, and attenuating these effects requires additional components to reduce, if not eliminate, the impurity concentrations to tolerable levels. These impurity management options increase the complexity of the fuel cell system, and they add to the capital and operating costs (regeneration, replacement and disposal of spent material, maintenance, etc.).

This project reviews the public domain information available on the impurities encountered in stationary fuel cell systems and their effects on fuel cells. A database has been set up which classifies the impurities, especially in renewable fuels such as landfill gas and anaerobic digester gas. It documents the deleterious effect on fuel cells and the maximum allowable concentrations of select impurities suggested by manufacturers and researchers. A generic model of a stationary fuel cell-based power plant is being developed; it includes a gas processing unit followed by a fuel cell system. The model is being used to conduct an economic analysis to estimate the effect of impurities (according to the class of materials, such as siloxanes) on

the cost of electricity. The model identifies the key relevant design and process parameters, and their effects on the capital and operating costs, as a function of the impurity content in the fuel feedstock.

Approach

The project evaluated the fuel feedstocks used in the stationary fuel cell power plants and identified the impurities and their concentrations that are typically present. The effect of these impurities on the fuel cell stack and suggested tolerance limits have been documented. The literature review helped identify the impurity removal strategies that are available and their effectiveness, such as capacity, cost, etc. A system model has been set up to consolidate the information and correlate the interactions and demands on the system. The key impurity removal steps are being modeled to enable predictions of impurity breakthrough, component sizing, and utility needs. The energy needs and process efficiency results from the model will be entered into the H2A model to calculate the cost of electric power. Sensitivity analyses will be conducted to correlate the concentrations of key impurities in the feedstock to the cost of electric power.

Results

Biogas from a waste digester contains 50-60% methane, with the balance of the biogas being mostly carbon dioxide, and is a viable fuel for fuel cell systems. It also contains trace contaminants some of which are produced by biological digestion while others are volatilized from the waste stream being digested. The contaminant matrix can be rather complex, containing many species that can be harmful to the fuel cell. The nature and amounts of such contaminants depend on the type and age of the waste, temperature, pressure, etc.

In general, while many contaminant species are present in biogas, three classes of impurities are of particular concern for its use in fuel cell systems.

- Reduced sulfur compounds are common in all biogas sources. The primary reduced sulfur compound of concern is hydrogen sulfide (H_2S), which may be present in biogas at concentrations up to several thousand parts per million by volume. While H_2S represents the bulk of sulfur in the biogas, organic sulfur, such as mercaptans and dimethylsulfide, is also present although typically in much lower concentrations (~1 ppm or less).
- Siloxanes emanating from personal hygiene products are generally present in landfill gas and wastewater treatment plant sludge digester gas in concentrations of 10 ppmv or less. Siloxanes (**silicon, oxygen, alkane**) are organo-silicon compounds with the formula R_2SiO , where R is H or a hydrocarbon group. Siloxanes can be cyclic (e.g., hexamethylcyclotrisiloxane [D3], etc.) or linear (e.g., hexamethyldisiloxane [L2], etc.). Out

of all the hundreds of different siloxanes in use, the most commonly occurring ones in landfill and biogases are L2-L5 and D3-D6 [1]. Siloxanes are converted to solid silica in flames. The solid silica may accumulate on surfaces inside power generation equipment and it can prematurely deactivate the catalytic surfaces in reformers and fuel cells.

- VOCs include alkanes, alcohols, aromatics and halogenated species. Of primary concern are halogens that can deactivate the catalytic surfaces in reformers and react with the electrolytes in fuel cells. Halogens from landfill gas generally originate from discarded refrigerants, plastic foams, etc. Many compounds are stable and slowly evaporate to maintain significant levels of halogens for many years. The concentrations of halogenated species from waste water treatment plants (WWTP) are typically below 1 ppm, while landfill gas may contain halogenated species up to about 40 ppm.

The requirements for gas cleaning will vary, depending on the type of biogas, impurity concentrations in the biogas and the tolerance limits to the impurities of the specific fuel cell system. A single gas purification step is seldom sufficient to clean the biogas; rather, a combination of methods is used to ensure a fuel quality that matches the tolerance limits for the fuel cell system. Reviewing the literature that includes case studies for fuel cell systems operating both on landfill gas and digester gas [2-5], it was found that the general gas cleaning strategies involve several steps, which can be broken down to a) primary clean-up of bulk impurities (e.g., H_2S with iron oxide) and b) gas polishing (i.e. adsorption) of trace contaminants of concern before the gas is delivered to the fuel cell system.

A generic model of a stationary fuel cell-based power plant has been developed to determine the overall electrical efficiency and costs of clean-up and maintenance, as a function of the biogas impurity matrix. A schematic of the fuel cell power plant is shown in Figure 1. A base case system considers a fuel cell system operated on digester gas from a waste water treatment plant. Major sections of the system include the gas processing system, fuel processor/fuel cell stack, and thermal management system. First the bulk impurity H_2S is removed using an appropriate sorbent, such as iron oxide media or impregnated activated carbon. The gas is further cooled to condense the water as moisture can significantly reduce the adsorption capacity in subsequent clean-up steps. The gas can even be deeply cooled to below $-20^\circ C$ to condense some of the siloxanes and heavier VOCs.

The dry gas is further passed to the secondary polishing equipment that can contain a series of adsorbents and removes organic sulfur, siloxanes, and halogens. The cleaned gas enters the fuel cell system where it is converted to electricity and usable heat. The heat generated by the electrochemical reaction is removed to an external heat rejection system, where it is recovered for use by the sewage treatment plant, in particular, to meet the energy needs for

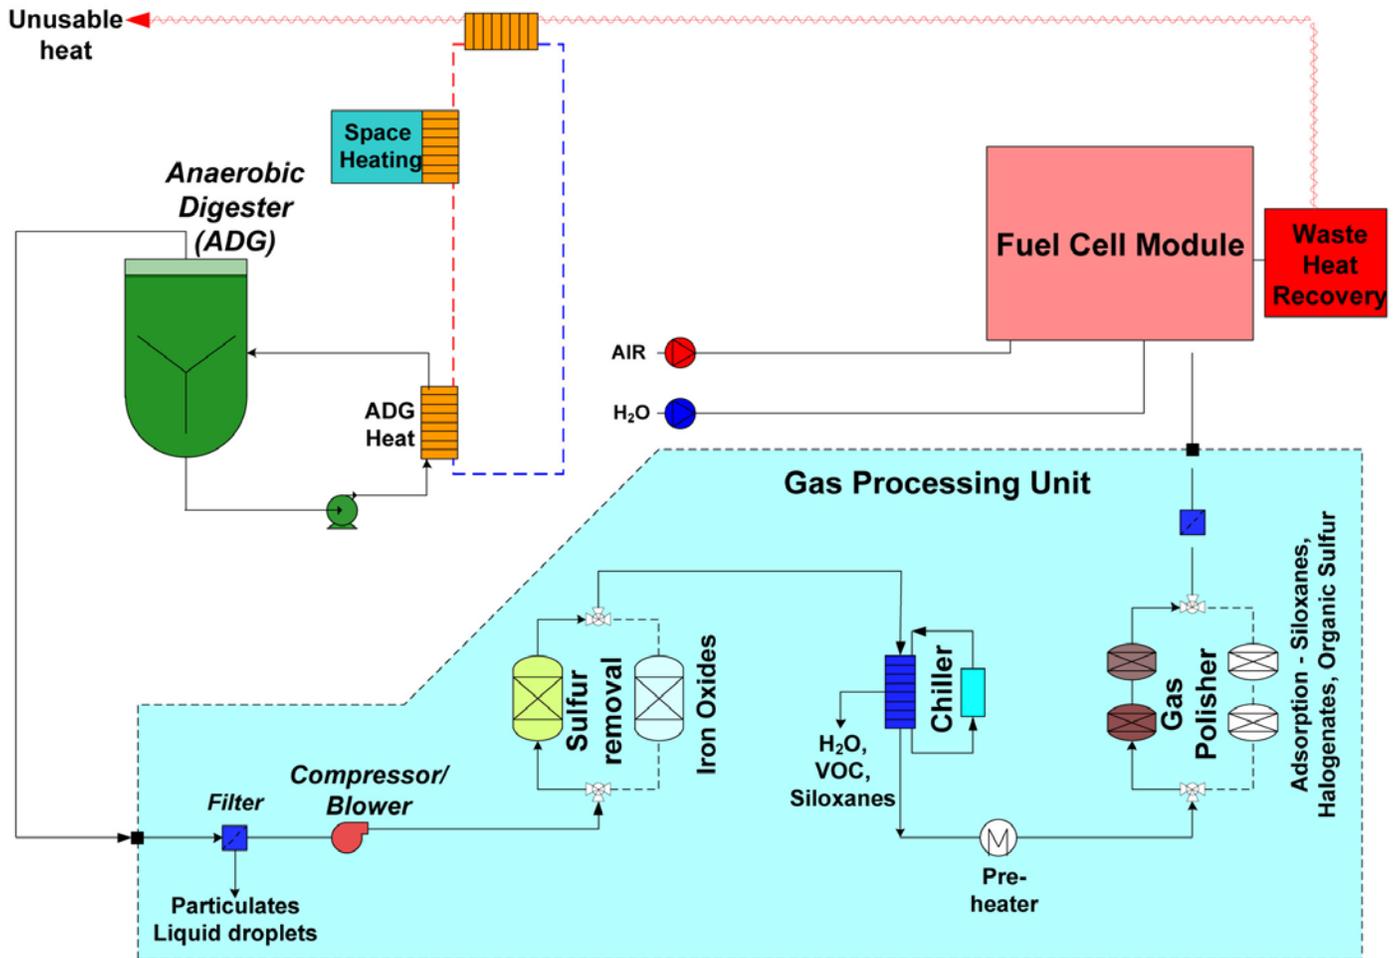

FIGURE 1. A Base Case Fuel Cell System Operating on Anaerobic Digester Gas

the anaerobic digestion process and, possibly, for other uses, e.g., space heating.

The overall process model has been set up initially for a molten carbonate fuel cell, and various component models are being developed to determine the utilization of the adsorbents (and, ultimately, the replacement costs) as function of impurity concentrations in the raw gas. For example, Figure 2 shows the adsorption capacity of activated carbon on some select trace impurities typically found in digester gas from WWTPs. The lines are modeled adsorption isotherms on pure organic components as a function of concentration (partial pressure) [6-7], and have been calibrated with available experimental data on activated carbon [8]. The shaded region in the graph is a range of concentration limits on a) the lower impurity tolerance limits for a fuel cell, and b) the typical maximum concentrations of individual trace impurities entering the gas polisher. Unsupported activated carbon has a rather low adsorption capacity for hydrogen sulfide, and so H₂S must be removed prior to the gas polisher. Some species, such as chlorobenzene and aromatics (e.g., toluene), show very high adsorption affinities for carbon, even at low

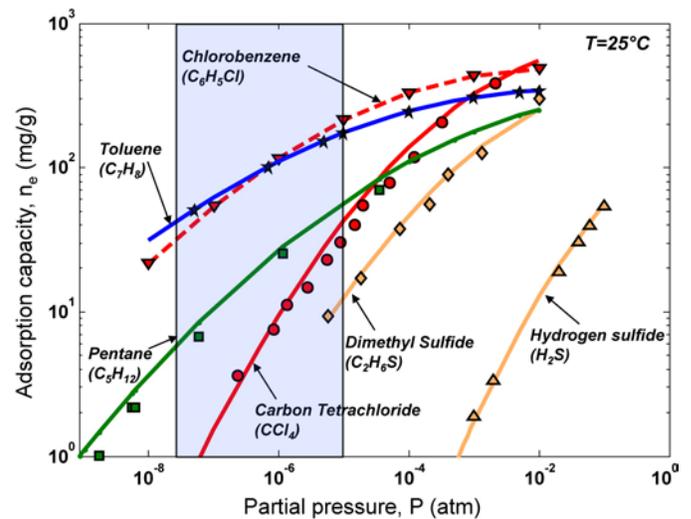

FIGURE 2. Adsorption isotherms on activated carbon (BPL) on some of the most frequent encountered trace impurities in digester gas. Solid lines are modeled pure component isotherms and symbols corresponding experimental data from the literature.

concentrations. Aromatics at ppm levels will not pose any hazard to the fuel cell system as such, but they will compete with available adsorption space and reduce the adsorption capacity for halogens and siloxanes – species of concern for the durability of the fuel cell system.

Conclusions and Future Directions

- Data available on biogas sources with respect to trace contaminant matrix and clean-up options and performance has been collected into a database. This information, along with the effects and removal of the various species that have significant deleterious effects on fuel cell performance or lifetimes, is categorized in classes of impurities, biogas source, and unit operations of the systems.
- Impurities of particular concern for the fuel cell system are sulfur, siloxanes, and halogens, which vary in concentration and speciation, depending on the biogas source of interest. Higher hydrocarbons, aromatics, and alcohols are also present in the biogas. While their concentrations may not be of direct threat to the fuel cell, they can greatly reduce the capacity of the various adsorbents to remove siloxanes and halides.
- A base case system has been set up for economic analysis and initially considers a molten carbonate fuel cell system operating on digester gas from waste water treatment plants. A generic model of a stationary fuel cell-based power plant has been developed, including component models of typical gas processing units, to determine the utilization of various adsorbents as a function of the biogas impurity type and concentration matrix.
- Cost data are being gathered for the various components in the power plant to complete the cost analysis for the base-case system. Further work will determine costs for different fuel cells, bio-gas sources, and clean-up technologies. Trade-off analyses between cost of clean-up versus degradation and power loss of fuel cell system are also important to determine life-cycle costs. Ultimately, these models and results will need to be validated with data from operating plants.

XII. AMERICAN RECOVERY AND REINVESTMENT ACT ACTIVITIES

XII.0 American Recovery and Reinvestment Act Activities

In April 2009, the Department of Energy (DOE) announced the investment of \$41.6 million in American Recovery and Reinvestment Act (ARRA or Recovery Act) funding for fuel cell technologies. These investments were made to accelerate the commercialization and deployment of fuel cells and to spur the growth of a robust fuel cell manufacturing industry in the United States, with accompanying jobs in fuel cell manufacturing, installation, maintenance, and support services. Twelve grants were awarded to develop and deploy a variety of fuel cell technologies, including polymer electrolyte membrane, solid oxide, and direct-methanol fuel cells in auxiliary power, backup power, combined heat and power, lift truck, and portable-power applications. The cost share provided by the project teams is about \$54 million, more than 56% of the total cost of the projects.

The ARRA fuel cell projects are addressing the objectives stated above as well as the overall ARRA goals of creating new jobs and saving existing ones, spurring economic activity, and investing in long-term economic growth. Significant progress toward these goals has been made, including the deployment of more than 830 fuel cells by the end of FY 2011, out of the total planned deployment of up to 1,000 fuel cells. These deployments have required project teams to address key challenges, including siting and permitting, fueling infrastructure, and fuel cell lifetime and reliability. These deployments have also attracted significant attention, with media events taking place at three of the ARRA deployment sites.

All ARRA project teams submit quarterly reports, which are available to the public through the Recovery.gov website. These reports include technology and deployment status as well as data on jobs created and funds spent. Collection and analysis of operational data from the fuel cell deployments are being performed by the National Renewable Energy Laboratory's (NREL's) Hydrogen Secure Data Center (HSDC) to assess the performance and commercial readiness of the fuel cell technologies. Data are aggregated across multiple systems, sites, and teams, and are made available on a quarterly basis through Composite Data Products (CDPs), published on NREL's website. Eleven presentations containing all CDPs have been published thus far, with the latest CDPs including performance, reliability, maintenance, and safety data for material handling equipment and backup power.

The Hydrogen Safety Panel has made four deployment site visits and has reviewed each project's safety plan. In addition, Sandia National Laboratories (funded through the Safety, Codes & Standards sub-program) has obtained two types of high-pressure hydrogen tanks for testing, from two ARRA project fuel cell partner companies and from tank manufacturers. Tank testing and analysis, which began at Sandia National Laboratories in FY 2010¹, are being done to facilitate market entry for fuel cell-powered lift trucks. This effort continues to address fatigue crack initiation and growth in steel tanks used in high-cycle applications. Testing thus far has shown the engineering predictions to be conservative relative to the performance of the pressure vessels—i.e., the number of cycles to failure has been higher than predicted. The procedures for pressure testing with gaseous hydrogen are being included in Canadian Standards Association HPIT1 and SAE International J2579 working documents for performance testing.

ARRA Project Summaries

Auxiliary Power

Delphi Automotive (Troy, Michigan and Rochester, New York): Delphi is developing a 3- to 5-kW solid oxide fuel cell (SOFC) auxiliary power unit (APU) for heavy-duty commercial Class-8 trucks at their laboratory in Rochester, New York. Delphi will test and demonstrate the diesel APU in a high visibility fleet vehicle that will provide power for vehicle hotel loads and other vehicle needs under real-world operating conditions. There will also be a series of in-house tests, including on-vehicle testing, to validate the “road worthiness” of the diesel APU prior to installation on the demonstration truck. Delphi will provide a comprehensive system specification and—with original equipment manufacturer partner PACCAR—will define commercial requirements. System development efforts will improve Delphi's current-generation SOFC technology by increasing net output power and fuel processing efficiency, decreasing heat loss and parasitic power loss, and establishing diesel fuel compatibility. The primary focus will be accelerating the development

¹“Component Testing for Industrial Trucks and Early Market Applications,” Daniel Dedrick et al., this volume.

and acceptance of the APU by the Class-8 heavy-duty truck market. Partners include Electricore Inc., PACCAR Inc., and TDA Research Inc.

Backup Power

ReliOn Inc. (Spokane, Washington): ReliOn is deploying backup-power fuel cell systems at approximately 190 telecommunications and utility network sites operated by AT&T and Pacific Gas & Electric (PG&E). These deployments span nine states, and they include the deployment of a refillable stationary hydrogen storage module and accompanying refueling logistics platform for AT&T sites. This effort will add reliability to communications networks where no backup power was previously available. ReliOn will provide DOE with data on installation, fueling logistics, and operations for fuel cells in voice and data communications networks in mountain, desert, and urban locations. Partners include Air Products & Chemicals Inc., AT&T, and PG&E.

Sprint Nextel Inc. (Reston, Virginia): Sprint Nextel is planning to demonstrate the technical and economic viability of deploying 1- to 10-kW polymer electrolyte membrane (PEM) hydrogen fuel cells with 72 hours of on-site fuel storage (using a new Medium Pressure Hydrogen Storage Solution with on-site refueling) to provide backup power for critical code division multiple access cell sites on the Sprint Wireless network. Over 200 new hydrogen fuel cell systems will be deployed at sites in California, Connecticut, New Jersey, and New York. Partners include Air Products & Chemicals Inc., Altery Systems, Black & Veatch Corporation, Burns & McDonnell Engineering Co. Inc., Ericsson Services Inc., and ReliOn Inc.

Plug Power Inc. (Latham, New York): This project will demonstrate the market viability of low-temperature, 6-kW PEM GenCore[®] fuel cells fueled by liquid petroleum gas (LPG) to provide clean and reliable primary power and emergency backup power (72 hours or more). Plug Power will install and operate 20 fuel cell systems at Fort Irwin in Barstow, California, and Warner Robins Air Force Base in Warner Robins, Georgia. These units will run continuously on LPG, providing power to the grid and will switch to emergency backup power during a grid failure. A small battery pack will be used to accommodate spikes in power demand. Partners include IdaTech, the U.S. Army Corps of Engineers' Construction Engineering Research Laboratory, Warner Robins Air Force Base, and Fort Irwin.

Combined Heat and Power (CHP)

Plug Power Inc. (Latham, New York): Plug Power is evaluating the performance of up to 12 high-temperature, natural gas-fueled, 5-kW micro-CHP fuel cell units (GenSys Blue[®]). The objective of the project is to validate the durability of the fuel cell system and verify its commercial readiness. Six units will undergo an internal Plug Power test regime to estimate failure rates, and up to six units will be installed and tested in real-world residential and light commercial end-user locations in California. Partners include Sempra Energy and the National Fuel Cell Research Center at the University of California, Irvine.

Fuel Cell-Powered Lift Trucks

FedEx Freight East (Harrison, Arkansas): FedEx is deploying 35 fuel cell systems as battery replacements for a complete fleet of electric lift trucks at FedEx's service center in Springfield, Missouri. Success at this service center may lead to further fleet conversions at some or all of FedEx's other 470 service centers. Partners include Air Products & Chemicals Inc. and Plug Power Inc.

GENCO (Pittsburgh, Pennsylvania): GENCO is deploying 357 fuel cell systems as battery replacements for fleets of electric lift trucks at five existing distribution centers (Coca-Cola in Charlotte, North Carolina; Kimberly Clark in Graniteville, South Carolina; Sysco Foods in Philadelphia, Pennsylvania; Wegmans in Pottsville, Pennsylvania; and Whole Foods in Landover, Maryland). Success at these distribution centers may lead to further fleet conversions at some or all of GENCO's other 109 distribution centers. Partners include Air Products & Chemicals Inc., Linde North America, and Plug Power Inc.

Nuvera Fuel Cells (Billerica, Massachusetts): Nuvera is deploying 14 fuel cell forklifts in H-E-B Grocery Company's distribution facility in San Antonio, Texas. Fuel will be supplied by Nuvera's natural gas reformer and its storage and dispensing system. Partners include H-E-B Grocery Co.

Sysco Houston (West Houston, Texas): Sysco is deploying 98 fuel cell systems as battery replacements for a fleet of lift trucks at Sysco's new distribution center in Houston, Texas, opened in March 2010. This

installation is the first-ever greenfield installation without prior battery infrastructure for a pallet truck fleet. Success at this distribution center may lead to further fleet conversions at some or all of Sysco's other 169 distribution centers. Partners include Air Products & Chemicals Inc. and Plug Power Inc.

Portable Power

Jadoo Power (Folsom, California): Jadoo is developing portable, propane-fueled SOFC generators and an electro-mechanical propane fuel interface as a potential replacement for traditional gas/diesel generators and lead-acid batteries. Two portable fuel cell generators will be deployed in this project. One of them will be used in a demonstration with police and fire first-responders in the City of Folsom, California, to power equipment in emergency and off-grid situations; both units will then be used to power media production equipment at automobile racing events at multiple locations throughout the United States. Partners include Delphi Inc., NASCAR Media Group, and the City of Folsom, California.

MTI MicroFuel Cells (Albany, New York): MTI is demonstrating a 1-watt consumer electronics power pack. The project is focused on improving reliability to meet the standards required by the electronics market and includes testing of individual components, subsystems, and complete direct methanol fuel cell (DMFC) systems. MTI is also developing manufacturing processes to improve product yields and reduce overall costs.

University of North Florida (Jacksonville, Florida): The University of North Florida is continuing work on a portable power system for use in mobile computing, further integrating and miniaturizing the components and analyzing failure modes to increase durability. The power system would be a DMFC that meets their initial commercial entry requirements for power density, energy density, and lifetime. The University will also conduct a design-for-manufacturability-and-assembly review to ensure that the systems meet their cost targets for commercialization. Partners include the University of Florida, Gainesville.

Data Collection & Analysis

National Renewable Energy Laboratory (Golden, Colorado): NREL is analyzing operational data (operation, maintenance, and safety) from the ARRA fuel cell deployments to better understand and highlight the business case for fuel cell technologies. Data collected by the project partners will be stored, processed, and analyzed in NREL's HSDC. Reports on the technology status will be generated on a quarterly basis, while technical CDPs will be published every six months.

FY 2011 Status and Accomplishments

As of the end of September 2011, more than 460 fuel cell lift trucks and more than 370 fuel cell backup-power systems for cellular communications towers and stationary backup-power systems had been deployed, and over 80% of the ARRA project funds had been spent by the projects. A total of 46 direct jobs have been created or retained as a result of these ARRA projects. Supply chain and other indirect jobs are not included—if it is assumed that at least three indirect jobs are created for each direct job, this would indicate that over 180 total jobs were created or retained as a result of these ARRA projects. NREL's HSDC has established data reporting protocols with each of the project teams. CDPs and detailed data products showing progress to date have been prepared. The CDPs are available on the NREL HSDC website, http://www.nrel.gov/hydrogen/proj_fc_market_demo.html. The Fuel Cell Technologies Program's ARRA projects were also included in a recent assessment of the impacts of government policy on the fuel cell industry.²

Auxiliary Power

Delphi Automotive Systems has initiated the system and subsystem vibration analysis and has completed over 20% of their planned thermal cycle testing on their A-Level SOFC APU. They have also conducted initial road testing, driving >3,000 miles with the unit mounted on a Peterbilt Class 8 truck. A new stack with improved system efficiency and new endothermic reformer with improved heat transfer and lower cost have been integrated into the B-Level, next-generation system. Over the next year Delphi will begin monitoring the SOFC APU performance in an on-road, real-world demonstration.

² *Status and Outlook for the U.S. Non-Automotive Fuel Cell Industry: Impacts of Government Policies and Assessment of Future Opportunities*, David Greene et al., May 2011, http://www.cta.ornl.gov/cta/Publications/Reports/ORNL_TM2011_101_FINAL.pdf.

Backup Power

ReliOn Inc. has completed the site qualification stage for the entire project. As of the end of June 2011, they have installed and commissioned over 270 fuel cells at 118 sites (109 for AT&T and nine for PG&E). Fourteen additional AT&T sites are undergoing construction, and nine more are pending. In 2011 ReliOn will construct and commission all remaining sites, and they will continue to obtain and report operational data to NREL's HSDC.

Sprint Nextel has completed over 580 site surveys at potential deployment sites for their fuel cell backup-power systems. They have installed and commissioned 32 new PEM backup-power fuel cells as of June 2011, with an additional 190 planned over the next year.

Plug Power has installed 10 GenCore[®] fuel cells at the Warner Robins Air Logistics Center, at Warner Robins Air Force Base. The units are providing backup power for lighting within the building. Plug Power also plans to install 10 additional fuel cells at an engineering building at Fort Irwin in Barstow, California, in FY 2012.

Combined Heat and Power

Plug Power is continuing durability tests on its six internal GenSys Blue[®] micro-CHP test systems, which were commissioned in January 2010. Since then, they have logged over 30,000 hours of stack operation, averaging over 30% electrical efficiency and over 85% thermal efficiency. In May and June 2011, three systems were installed at the National Fuel Cell Research Center at the University of California, Irvine, for real-world testing in a light commercial environment. The National Fuel Cell Research Center has also continued its dynamic modeling work of the GenSys Blue[®] system. Over the next year, Plug Power will install fuel cell systems in at least one Sempra Energy customer site in California. A customer site has already been recommended for the first installation.

Fuel Cell-Powered Lift Trucks

FedEx Freight East deployed 35 Class-1 fuel cell-powered lift trucks in June 2010, at their 53,000 square-foot distribution center in Springfield, Missouri. Due to the favorable operational results, they purchased an additional five fuel cell lift trucks, *without any additional DOE funding*. As of April 2011, the lift trucks have accumulated over 28,000 hours of operation and used 13,500 kilograms of hydrogen. FedEx has already seen 30–60% more operating hours in between repairs for fuel cell lift trucks than for propane-powered internal combustion engine lift trucks. Over the next year they will continue to monitor the performance of their fuel cell lift truck fleet, and they plan to work with Plug Power on resolving issues related to cold-weather operation.

GENCO has deployed over 270 GenDrive[®] fuel cells in lift trucks across five distribution facilities as of May 2011. The lift trucks at Wegmans in Pottsville, Pennsylvania, Whole Foods in Landover, Maryland, and Kimberly Clark in Graniteville, South Carolina, are fully deployed and operational. Some of the power units at the Wegmans site have already accumulated over 5,000 hours of operation. Coca-Cola and Sysco Philadelphia have initiated deployments of fuel cell lift trucks, and over the next year, GENCO will deploy the remaining fuel cells to Coca-Cola and Sysco Philadelphia.

Nuvera Fuel Cells installed 14 PowerEdge[™] fuel cells in lift trucks and installed their PowerTap[™] hydrogen infrastructure technology at the H-E-B Grocery Co. distribution center in San Antonio, Texas. As of May 2011, Nuvera's on-site reformer had generated 5,570 kilograms of hydrogen and had maintained 100% hydrogen availability at the pumps. Their lift trucks have accumulated nearly 22,900 hours of operation and have demonstrated a 10% productivity gain over battery-powered lift trucks. Based on the success of this deployment site, H-E-B plans to purchase 28 additional PowerEdge[™] fuel cell units, requiring two additional PowerTap[™] systems—*with no additional DOE funding*.

Sysco Houston has deployed 98 hydrogen fuel cell-powered Class-3 pallet trucks and Class-2 forklifts at their 585,000 square-foot food distribution facility in Houston, Texas. As of February 2011, the lift trucks had accumulated over 300,000 hours of operation and used 17,620 kilograms of hydrogen (from 31,000 fueling events). While Sysco Houston is currently not experiencing any difference in cost between charging batteries and fueling with hydrogen, they are saving nearly \$100,000 annually in fewer man-hours spent refueling

lift trucks compared with swapping batteries. Based in part on the success of this deployment site, Sysco Corporate is planning to replace about 1,000 batteries with 500 or more fuel cells at seven sites over the next 24 months—with no additional DOE funding.

Portable Power

Jadoo Power has completed a detailed analysis of the power needs of NASCAR’s cameras. Desulfurizer hardware from Delphi has been fully tested, and the reformer testing is near completion. Jadoo’s propane fuel interface has been developed and is ready for system integration testing. They have also created preliminary designs for the overall system packaging. Over the next year, Jadoo plans to deploy the systems for the field trial and begin to collect data on the units.

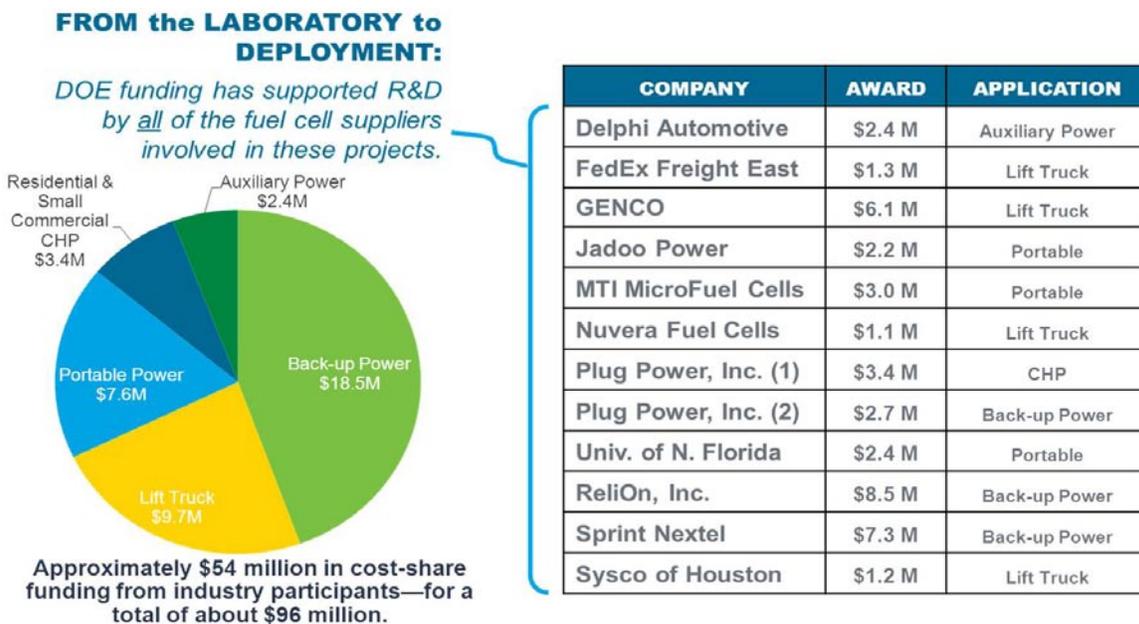

MTI MicroFuel Cells has demonstrated high performance, high fuel efficiency, and low degradation for a one-watt DMFC charger for consumer electronics. They have achieved or exceeded all their technical metrics for the project. MTI sent out 75 complete systems to be tested in real-world environments by individuals, original equipment manufacturers, and government and military personnel. Overall feedback from the field tests has been very positive, and MTI plans to use the data gathered to guide future product development.

The University of North Florida has nearly completed component and subsystem testing for the DMFC portable power system. As of June 2011, three brassboards have been tested, with over 500 hours of operation on each system at multiple locations. The design for the packaged system is complete, with the subassemblies in the manufacturing and assembly phase. The University will assemble multiple packaged systems and test them extensively to evaluate performance, robustness, and durability.

Data Collection & Analysis

NREL has published six deployment-focused CDPs and three cycles of technical CDPs—composed of 42 CDPs for material handling equipment and 10 CDPs for backup power. In addition, they have provided hundreds of detailed data results to the individual projects. NREL has created a website to host these published results and presentations. Over the next year, they plan to continue collecting and analyzing ARRA deployment data and publishing the results on their website.

Budget

FY 2012 Plans

Continued data collection on performance and productivity at the various deployment sites is a priority for FY 2012. In FY 2012, deployment of over 250 additional fuel cell systems for backup power, combined heat and power, and lift truck applications is planned. Five projects are expected to end in early FY 2012. All projects will conclude by the end of FY 2013.

Finally, in FY 2012, DOE will continue to document the lessons learned associated with the ARRA projects, including strategies developed for market entry and management of risks relating to safety, environmental, and siting requirements. Energy Efficiency and Renewable Energy will initiate an evaluation in FY 2012, focused on early-stage “market change” impacts (for the period of 2010 through the end of 2012), of the Recovery Act fuel cell deployments.

Contract Number: EE0000477

Project Start Date: January 8, 2009

Project End Date: March 31, 2011

Technical Barriers

Progress against the barriers listed below is discussed in the following sections.

- Cost and manufacturability
- Performance and degradation
- Market acceptance

Accomplishments

- Deployed 75 fuel cell systems into the field for real world evaluation.
- Reduced cost and improved manufacturability and assembly.
- Demonstrated high performance, high fuel efficiency, and low degradation.
- Demonstrated system temperature and humidity latitude (0-40°C, 0-90% relative humidity).
- Achieved or exceeded all technical metrics.

Objectives

Demonstrate and field test a commercially viable 1 Watt direct methanol fuel cell (DMFC) charger for consumer electronic devices:

- Design for low-cost, high-volume manufacturing processes and ease of assembly.
- Demonstrate performance across temperature and humidity range of consumer electronic devices.
- Deploy 75 units into the field to obtain real world usage feedback.

Relevance to the American Recovery and Reinvestment Act (ARRA) goals of saving and creating jobs:

- Project funding created/retained 11 full-time equivalent jobs in Albany, NY.
- The DOE funds enabled MTI to obtain private investment.

Relevance to the U.S. DOE Fuel Cell Technologies (FCT) ARRA goals of accelerating the commercialization and deployment of fuel cells:

- Components have been redesigned for low-cost, high-volume manufacturing.
- Seventy-five fuel cell systems have been deployed during field test.

Introduction

The objective of this project is to demonstrate and field test a commercially viable 1 Watt DMFC charger for consumer electronic devices. The fuel cell system and replaceable methanol cartridge will meet all requirements for commercialization. The system will achieve targets of cost, performance, and design reliability at a level compatible to the standards and requirements of the consumer electronics market.

Approach

The project's environmental and safety plans had been developed and submitted during 2009. The project has been organized into three phases.

The tasks in phase 1 include component cost reduction, redesign for manufacturability, performance and reliability testing, and system integration. Phase 2 tasks include tool fabrication, debugging, and tooled component prove-out in working systems. Phase 3 tasks include demonstrating the DMFC charger's functionality in the hands of real users while also providing feedback for potential design improvements. This field test is the first time a significant number of MTI units (shown in Figure 1) are put into the field to test usability and functionality. The objective of the field test is to generate user feedback on product viability as well as identify potential product improvements.

Results

A major focus of this project was to reduce the cost of MTI's DMFC-powered charger to attain a competitively priced product when in production. To achieve a low cost system many of the components had to be redesigned so that they could be produced using low-cost, high-volume, manufacturing processes. The system also had to be redesigned for ease of assembly to increase build yield and reduce the amount of labor content needed. In addition, the assembly process had to be simplified so that technicians and assemblers could perform the assembly rather than engineers and scientists.

During phase 1 of this project many parts and process steps were completely eliminated or were significantly simplified. In one instance a complete subassembly, with all associated cost and reliability issues, was eliminated. At the completion of phase 1 almost all components were redesigned for reduced cost and high volume manufacturing. The following are examples of component redesigns implemented to reduce cost and make the components capable of being manufactured using common, low-cost, high-volume manufacturing processes:

- Plastic components previously machined were designed to be injection moldable.
- Sheet metal components previously machined were redesigned to be stamped.

- Many adhesives and small bridge plates were completely eliminated by integrating their function in other interfacing components.

During phase 2 of the project, tools were fabricated and parts were produced for evaluation of the design intent product. This required several iterations of part, tool and process changes until the parts produced off of the tooling met the design requirements. Comprehensive subsystem level testing was carried out to quantify the impact the redesigned subsystems had on durability and performance. There was also a significant amount of system integration work done to bring the new lower cost subsystems together. Testing at the system level was used to verify that the system is capable of operating well during transients such as start-up and shut-down and at all specified temperatures, humidity, and orientations.

During phase 3 of the project 75 user evaluation kits were sent out which contained the contents shown in Figure 2. The kit included a mobion handheld generator, two cartridges filled with methanol, quick start guides, and a cable that had interchangeable tips enabling use with all of the common connections for handheld electronic devices. Although only two cartridges were sent with the units there were more available upon request.

The fuel cell systems were deployed to the groups specified in the statement of work including individual users,

FIGURE 1. MTI Mobion DMFC Charger

FIGURE 2. Contents of Box Field Trial Participant Received

original equipment manufacturers (OEMs), various military groups and government agencies. The allocation of the units is shown in Figure 3.

Feedback from the field test has been very positive overall. Below are some verbatim comments from the participants within the larger groups that have participated in the field trial:

- *“Just finished off my first cartridge today. I charged my (iPhone) phone approx 10x from ~25% to 100% battery before it needed replacement” – OEM*
- *“We were impressed with the form factor and with the chemical conversion technology. It repeatedly charged our iPhones in a timeframe similar to that from a standard electrical outlet.” - OEM*
- *“The device works excellently and has not provided many inconsistencies. Mostly, not being able to have the fuel cell in an enclosed space (i.e., laptop bag) while it is generating power was an inconvenience though not a major problem.” – Individual user*
- *“Alternative energy on the battlefield is evolving into one of the most salient issues of the day. We believe that despite initial concerns, Mobion should continue advancement of this unique technology to potentially meet some of the existing and future tactical energy requirements.” - Military*

An online post-test survey was used to capture user feedback. Figure 4 shows results from one of the questions on the survey that captured the attributes users liked.

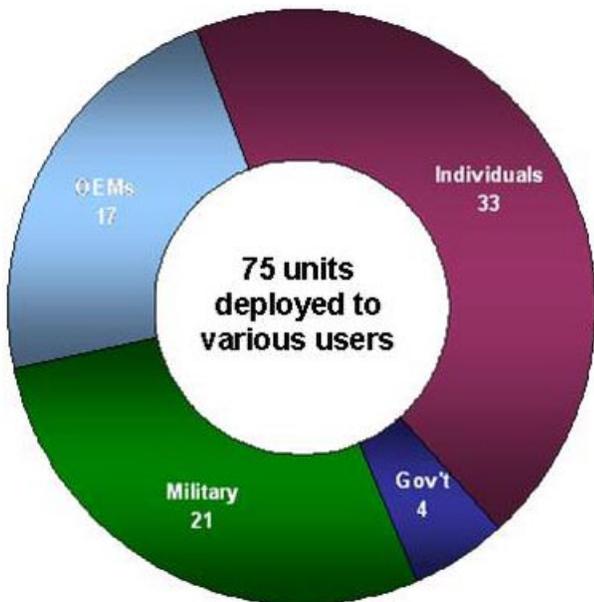

FIGURE 3. Allocation of the 75 Units Deployed for Field Trial

This field trial accomplished the objective of obtaining real world usage feedback and identifying areas of product

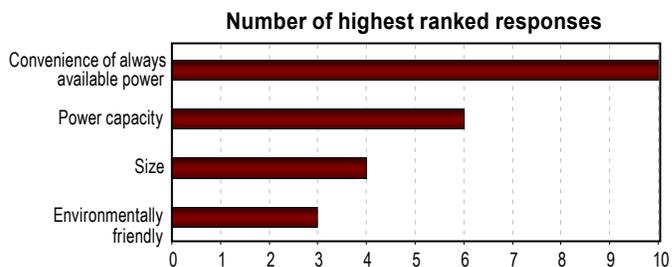

FIGURE 4. Results from Feedback Form - What Users Liked

improvement. Valuable feedback was coming in just days after the initial units were being shipped. For example, there was a compatibility issue the fuel cell had when connected to one of the newer smart phones. The issue was quickly resolved and did not reappear throughout the duration of the trial. This issue exemplifies the enormous value the field trial added to the product development process. There are some issues, such as the one described, that will not show up in the lab and that will only be uncovered when units are deployed into the field in significant numbers. The user interface was another area that benefited greatly from this user field test. The user interface functioned well but was confusing to some users because it had two buttons. The feedback on the user interface from this field trial led to the development of a new single switch user interface and other features to make the device more intuitive.

A secondary benefit of the field trial was that it enabled the participant and the organizations they represent to become aware of the commercial readiness of this product. In general, the participants that have evaluated fuel cell offerings from other companies in the past were most impressed with the Mobion charger during the field trial. Sending units for evaluation gave credibility to the product claims, specifications, and commercial readiness. Several business relationships initiated or strengthened by the field trial will further impact the commercialization of this product and technology in the coming months.

Conclusions and Future Directions

- High power density and high fuel efficiency has been achieved simultaneously.
- Low stack degradation rate exceeding product requirements has been demonstrated.
- Performance of system at temperature and humidity latitude (0-40°C, 0-90% relative humidity) has been demonstrated.
- Seventy-five unit field test has been completed:
 - Seventy-five units built, tested, and shipped
 - Product improvements identified

Although this project is complete several product improvements have been identified that will continue to guide our product development in the coming months.

E-mail: Greg.Kleen@go.doe.gov

Contract Number: DE-EE0000479

Subcontractor:

Delphi Automotive, Rochester, NY

Project Start Date: January 1, 2010

Projected End Date: September 9, 2012

Objectives

- The development of two portable electrical generators in the 1,000 watt range utilizing solid oxide fuel cells (SOFCs) as the power element and liquefied petroleum gas (LPG) as the fuel.
- The development and demonstration of a proof-of-concept electromechanical LPG fuel interface that provides a user-friendly capability for managing LPG fuel.
- The deployment and use of the fuel cell portable generators to power lighting and video production equipment over the course of several months at multiple National Association for Stock Car Auto Racing (NASCAR) automobile racing events.
- The deployment and use of the fuel cell portable generators by first responders (police, fire) of the City of Folsom, California to power equipment in emergency and/or off-grid situations.
- Capturing data with regard to the systems' ability to meet DOE technical targets and evaluating the ease of use and potential barriers to further adoption of the systems.

Relevance to the American Recovery and Reinvestment Act (ARRA) of 2009 Goals

This project will create or save existing jobs and spur economic activity in California and New York. This

project will demonstrate the efficacy of fuel cell generators in multiple applications that have near-term potential for commercialization and development of the fuel cell market.

Technical Barriers

- Reducing stack and balance of system to size allowing portability.
- Reliability of SOFC system under rough field conditions.
- User factors related to start-up times and refueling.
- Effectiveness/complexity of processing LPG to remove sulfur.
- Potential constraints on type or source of LPG.

Technical Targets and Milestones

- Develop LPG desulfurizer - reduce the level of sulfur in LPG to less than 10 ppb for eight continuous hours.
- Develop SOFC portable generator - produce 1 kW using LPG for eight continuous hours.
- Operation of generator at minimum 30% efficiency for minimum of 2,000 cumulative hours.
- Develop a user-friendly electromechanical LPG fuel interface — indicate the amount of LPG within $\pm 10\%$ of the actual amount for the entire range from full to empty.
- Test two SOFC generator units at several NASCAR racing events as replacements for gasoline powered generators.
- Test SOFC generators in first responder applications with Folsom Police and Fire Departments.
- Analyze technical performance and human factors issues to evaluate readiness of the technology to move into commercialization phase.

Accomplishments

- Detailed analysis of NASCAR camera equipment power needs completed including baseline load evaluation and logistics evaluation.
- Focus group with City of Folsom, City of Sacramento, Office of Emergency Services, CalFire and Federal Emergency Management Agency has been conducted.
- Requirements definition completed.
- Desulfurization development and testing completed.
- Reformer development near completion.
- Mechanical packaging design and system testing underway.
- LPG fuel interface ready for system integration testing.

Introduction

Deploying a commercial power system into a portable space is a challenge for fuel cell applications. Moving a fuel cell power system from the laboratory to consumers' hands requires a complete systems or solution approach. A portable application requires consideration for real world conditions; requiring a wide array of control and power electronics to handle load following, startup/shutdown, safety considerations and system security. A level of ruggedness to handle frequent shocks from deployment and shipping is necessary as well as a convenient and safe fuel system interface. Jadoo has identified several specific applications related to outdoor sporting events and emergency response that are ideally suited to the technical characteristics of fuel cells and which would gain significant benefit from a fuel cell generator that could replace existing gasoline or diesel powered generators. This project entails the development of a portable fuel cell generator utilizing LPG fuel that can address the targeted applications.

Approach

Portable generators are to be developed by leveraging parallel work by Delphi Automotive related to use of a SOFC in a trucking auxiliary power unit (APU) application. Delphi SOFC technology will be modified and packaged for portable application with alternating current power capability. Delphi is modifying a reformer from its diesel APU to allow the use of LPG. Delphi is also developing a desulfurizer to allow use of commonly available consumer grade LPG as fuel source. Jadoo Power is developing an electromechanical fuel interface by leveraging prior learning from the development of an interface between proton exchange membrane fuel cells and metal hydride canisters for use by non-technical personnel.

Results

The requirements of the NASCAR application have been characterized. The general areas addressed include electrical power requirements, runtime requirements, and portability and mechanical requirements. One key application that has been targeted for application of the fuel cell generators is providing power to television cameras. These consist of fixed camera locations (with and without special effects modules) that are operated by camera people and remote camera locations with robotic mechanisms that are operated by a remotely located camera person. The power levels of the typical locations are shown in Table 1.

The desulfurizer subsystem has been selected, qualified and tested. A continuous performance test of the LPG desulfurizer for 40 hours has been conducted using a high sulfur content LPG source. The analysis data showed all

TABLE 1. Television Camera Power Requirements Summary

CAMERA TYPE	NOMINAL POWER	PEAK POWER
Fixed camera without special effects module	150 Watts	170 Watts
Fixed camera with special effects module	200 Watts	220 Watts
Robotically assisted Remote camera	100 Watts	175 Watts

sulfur species in the desulfurized LPG was generally below detection limits. Hence with an estimated dilution factor of 5~8, total sulfur level in the corresponding reformat would be expected to be <10 ppb.

The reformer subsystem development and testing have been completed. Bench testing and characterization has demonstrated performance levels are at or near design targets.

Preliminary designs have been completed for the overall system packaging utilizing a "pit-box" form factor as shown in Figure 1. This form factor was selected as it is consistent with other equipment utilized by NASCAR and is compatible with the transportation requirements.

The LPG fuel interface prototype has been designed, fabricated and assembled (see Figure 2) and is ready for system integration testing.

Conclusions and Future Directions

The key technical risk elements of this development have been successfully addressed in bench testing and subsystem level implementations. The form factor will be larger than anticipated but will still be suitable for many application identified for the field trials.

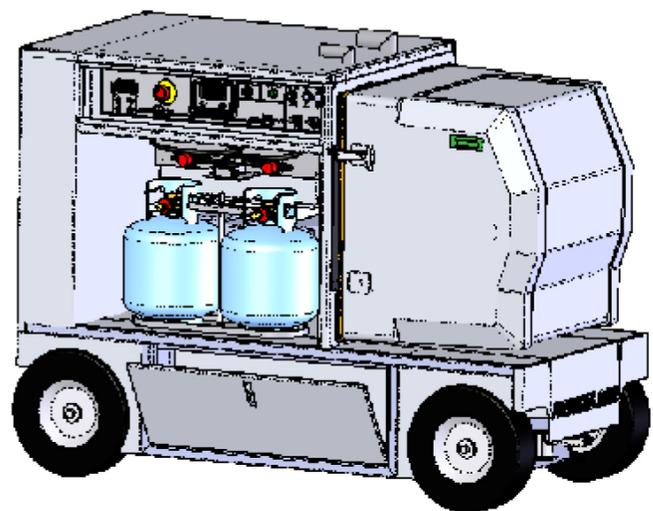

FIGURE 1. Mechanical Chassis Model

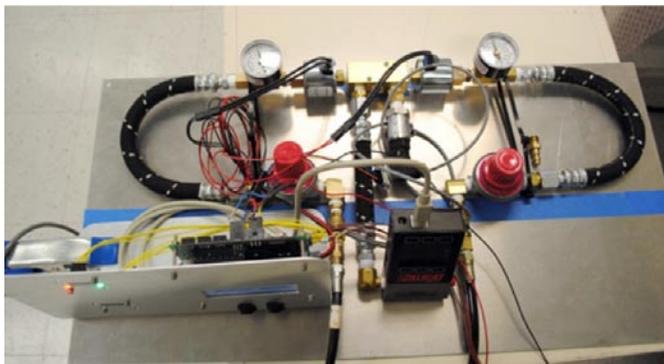

FIGURE 2. LPG Fuel Interface

The key remaining steps related to the program are as follows:

- Test the LPG interface to demonstrate measurement accuracy of +/- 10%.
- Fabricate the mechanical chassis.
- Integrate the subsystems together on the mechanical chassis.
- Perform system level testing and validation.
- Deploy the systems in the field trial with NASCAR.
- Deploy the systems in the field trial with the City of Folsom, CA.
- Gather the field trial data and prepare the final reports.

Contract Number: DE-EE0000476

Subcontractor:
 University of Florida, Gainesville, FL

Project Start Date: January 1, 2010
 Project End Date: December 31, 2011

- Reduce the necessity and use of the power grid as fuel cells power increasing numbers of portable electronic devices, thereby creating more “green” jobs.
- Create more business activity in the fuel cell supply industry.
- Expand the user base of new alternative power technologies.
- Increase the level of competition among producers of alternative energy technologies.

Technical Barriers

This project addresses the following technical barriers for advanced DMFCs outlined by the DOE.

- Specific power
- Energy density
- Operating lifetime
- Manufacturing Cost
- Balance-of-plant components

Technical Targets and Milestones

TABLE 1. UNF Progress toward Meeting Technical Targets for Advanced Direct Methanol Fuel Cell for Mobile Computing

Characteristic	Units	UNF 15 W DP3 2008 Status	DOE 2010 Target	UNF Proposed 20 W System Design
Specific Power ^a	W/kg	35	100	54
Power Density ^a	W/L	48	100	63
Energy Density	W-hr/L	250 (1 x 100 ml) ^b 396 (1 x 200 ml) ^b	1,000	198 (1 x 100 ml) 313 (1 x 200 ml) 507 (3 x 200 ml)

^b Normalized from Design Prototype 3 (DP3) data from 150 ml cartridge to either 100 ml or 200 ml for comparison purposes.

^c Lifetime measured to 80% of rated power.

Objectives

- The project objective is to develop a direct methanol fuel cell (DMFC) power supply for mobile computing using the novel passive water recycling technology acquired by UNF from PolyFuel, Inc., which enables significant simplification of DMFC systems.
- The objective of the 2011 effort is to build on the objectives completed in 2010 in order to finalize the system design, build and test the packaged 20 W power supply. To date, the system components have been selected and integrated into a brassboard (unpackaged system) for in situ testing. Based on the feedback provided by brassboard and component testing, the final design has undergone minor design revisions. The packaged system is currently in the manufacturing and assembly phase, once the system assembly has been completed, control strategies will be applied and optimized for the packaged system.

Relevance to the American Recovery and Reinvestment Act (ARRA) of 2009 Goals

This project will contribute to the relevance of DOE’s objectives for ARRA projects in general and the DMFC projects in particular.

- Create direct and supporting jobs nationwide as the UNF fuel cell technology becomes commercially available.

Accomplishments

- Submission of revised Hydrogen Safety Plan.
- Baseline testing of components and subsystems complete.

- Integration of subsystems/components into brassboard (unpackaged system).
- Completion of three separate brassboards with hundreds of hours of operation at multiple locations.
- Control strategy optimization from brassboard operation.
- Preliminary design review held for packaged Design Prototype 4 (DP4) system.
- Packaged system components currently in manufacturing and assembly phase.
- Passed Go/No-Go milestone review in January 2011.

Introduction

The project objective is to develop a DMFC power supply for mobile computing using the UNF novel passive water recycling technology which enables significant simplification of DMFC systems. The objective of the 2011 effort to date is to perform system engineering and extensive brassboard (unpackaged) testing to move towards the 2010 technical targets. The remainder of the project will focus on optimizing the performance of the packaged system.

Approach

This project is focused on balance of plant (pumps, blowers, sensors, etc.) development and overall system integration. These components will be rigorously tested individually, as subsystems, and ultimately at the system level. Initially, existing components will be evaluated for durability and failure modes, and the results will be used to further define component requirements. Once available, the design prototype components will be evaluated for durability and robustness. Subsystems will be integrated for testing, first onto a brassboard enabling detailed instrumentation of the system and verification of sub-system design, and then into an integrated package with auxiliary instrumentation. Control system development will optimize the key operational protocols for start-up, rest/rejuvenation, and shut-down to optimize operating lifetime and minimize both operational and storage degradation rates. In addition, this effort is highly integrated with the UNF-led Topic 5A: New MEA Materials for Improved DMFC Performance, Durability, and Cost project (DOE funded) which focuses on optimizing the passive water recovery membrane electrode assembly (MEA).

UNF submitted a Hydrogen Safety Plan for initial review on June 30, 2010. Based on very helpful comments received on from a DOE reviewer received on December 13, 2010, a revised plan was submitted to DOE on February 28, 2011.

Results

In order to progress towards the DOE 2010 technical targets for advanced DMFCs for mobile computing, it is

imperative that each component in the system be tested for both optimal efficiency and robustness. Therefore, an extensive test plan was executed for each component/subsystem with the DP4 system.

The cathode blower subsystem was optimized using two separate methods. First, performance of numerous fans was tested against the component requirements in order to select the optimal cathode fan for the design condition. As shown in Figure 1, the ADDA AD4505HX-K90 offers the lowest parasitic power compared to the other fans that were tested. The ADDA fan has since undergone over 2,000 hours of durability testing while still meeting the design requirements.

The second series of tests that were conducted with the cathode blower subsystem examined flow optimization. This testing revealed the optimal cathode flow channel depth/configuration as well as the sensitivity of spacing between the fan and fuel cell stack inlet.

The recirculation pump used to flow the anode solution through the stack and support components (reservoir tank, gas liquid separator, etc.) was extensively tested. Numerous pumps were selected for testing based on the design requirements. Extensive testing showed that the KNF5 is significantly more efficient than other similar pumps relative

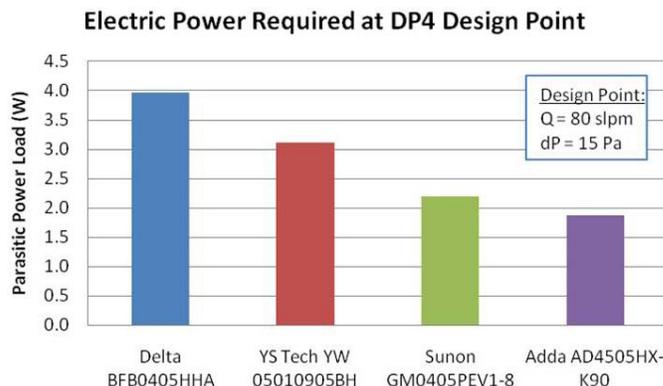

FIGURE 1. Comparison of Candidate Cathode Fan Performance

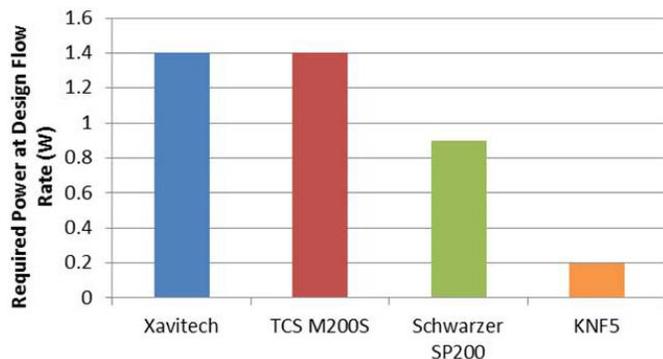

FIGURE 2. Comparison of Candidate Recirculation Pump Performance

to size, weight and hydraulic performance (Figure 2), thus resulting in the best system power and energy density.

The methanol injection pump that was selected for use in the DP4 is one of the few pumps that were able to meet the design requirements. Although the Microbase MBP2115BD has been able to provide hundreds of hours of operation during harsh environmental conditions, testing has revealed inconsistencies in the performance from pump to pump. Currently, testing is underway to determine if there is a significant variation in pump performance due to manufacturing.

The FC-10 methanol sensor was selected as the primary candidate for system integration. Extensive testing was conducted in order to determine any sensitivities to drift or thermal effects. It was determined that the FC-10 has a high sensitivity to temperature fluctuations. In addition, the sensor is not optimized for the application due to size, weight and cost. Therefore other methanol sensing technologies are under active investigation from manufacturers Spreeta and Japan Radio Corporation.

The gas liquid separator has undergone multiple revisions and tests to better understand the behavior of extruded Teflon[®] and the effect of its performance relative to temperature, pressure and ambient conditions. As a result, a significant reduction in the amount of water loss through the gas liquid separator has been achieved compared to the previous generation gas liquid separator.

The near completion of component and subsystem testing allowed for the design and assembly of the DP4 brassboard (Figure 3). To date, three brassboards have been assembled and tested with over 500 hours of operation on each system at multiple locations. The brassboards have allowed for components and subsystems to be tested in an in situ environment. Hundreds of hours of in situ testing highlighted design revisions and modifications in order to improve overall system reliability and robustness. The brassboard has also enabled accelerated evolution of software code revisions due to its accessibility and ease of use. Furthermore, the control strategies along with

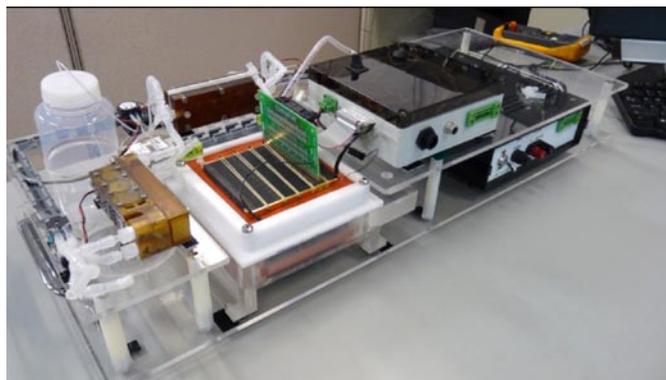

FIGURE 3. DP4 Brassboard (Unpackaged) System

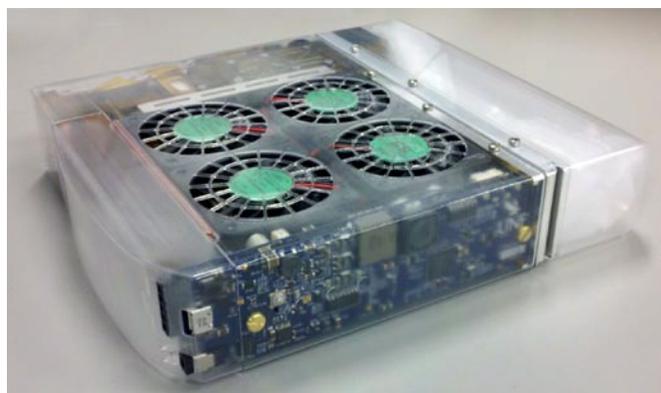

FIGURE 4. Packaged 20 W DP4 Fuel Cell Power Supply

the startup and shutdown algorithms have been greatly improved in order to better handle dynamic conditions and different system configurations.

The DP4 packaged system (Figure 4) concept design review was held at the beginning of 2011. Since then, the system has undergone minor design revisions due to the feedback provided from brassboard and component testing. The system is now in the final design stage and integrated prototypes are in the manufacturing and assembly phase. In addition to the completion of the mechanical design, the control board design has been completed and has been sent out for manufacturing. The first packaged system was presented at the Annual Merit Review meeting presentation in May of 2011 and is now in the testing phase.

Conclusions and Future Directions

- System components were tested to establish a benchmark to determine the system requirements.
- The best components were selected to meet the design requirements of the system and were subjected to durability and robustness testing.
- Each component was incorporated into its respective subsystem assembly and integrated into the brassboard system.
- In situ testing provided by brassboard operation allowed for component and control strategy optimization.
- Packaged system design is complete and subassemblies are in the manufacturing and assembly phase.
- Assemble multiple packaged systems for testing.
- Complete development of advanced control strategies with packaged system.
- Test the system extensively to evaluate performance, robustness, and durability.

Contract Number: DE-EE0000478

Subcontractors:

- Electricore, Inc., Valencia, CA
- PACCAR, Inc., Bellevue, WA
- TDA Research, Inc., Wheat Ridge, CO

Project Start Date: August 1, 2011
Project End Date: January 31, 2012

that will support hotel loads and other real world operating conditions.

Relevance to the American Recovery and Reinvestment Act (ARRA) of 2009 Goals

- During this phase of the project, a total of 21 jobs were created/maintained:
 - Delphi 18 jobs
 - Electricore 1 job
 - PACCAR 1 job
 - TDA 1 job
- As a result of this project, Delphi will be able to install its SOFC APU on a high visibility fleet truck. This will provide Delphi, and its fleet customer, with real world use experience as well as the associated fuel consumption and emission data. This demonstration should increase the overall awareness of SOFC APUs and provide positive momentum in preparing to commercialize this product.

Technical Barriers

- As a result of the successful execution of this project, Delphi will have addressed:
 - System vibration robustness
 - Overall system packaging
 - System weight
 - System cost
 - System manufacturability
 - System durability/reliability
- During a recent SOFC APU system test, we discovered an issue with the desulfurizer during repeated thermal cycles. This issue needs to be resolved before the unit could begin fleet testing.

Objectives

- Design, develop, and demonstrate a 3-5 kW solid oxide fuel cell (SOFC) auxiliary power unit (APU) for heavy-duty commercial Class 8 Trucks (Figure 1).
- Utilize Delphi's next generation SOFC system as the core power plant and prove the viability of the market opportunity for a 3-5 kW diesel SOFC APU system.
- Test and demonstrate the diesel SOFC APU system in a high visibility fleet customer vehicle application

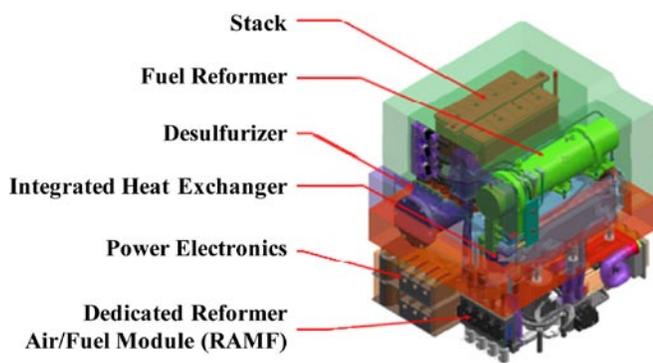

FIGURE 1. Delphi Solid Oxide Fuel Cell Auxiliary Power Unit (A-Level Prototype) Schematic

Technical Targets and Milestones

- Build next generation prototype (B-Level) SOFC APU for installation on fleet customer truck during the fourth quarter of 2011. Begin on-road, real-world application demonstration.
- Provide 3-5 kW of power during idle periods allowing for reduced fuel consumption and harmful emissions.
- Specific power ≥ 15 w/kg.
- Power density ≥ 10 w/l.
- Net system efficiency $\geq 35\%$.
- $\geq 2,000$ hours of operation.

Accomplishments

- A-Level SOFC APU mounted on Peterbilt Class 8 truck and driven >3,000 miles (Figure 2):
 - SOFC APU air inlet was modified based upon data from road-test.
- A-Level SOFC APU completed >50 thermal cycles of 250 planned.
- System and Subsystem vibration analysis initiated:
 - System tested to the equivalent of 17,000 highway miles on a vibration table.
 - Stack tested to the equivalent of 3.5-million miles on a vibration table.
- Integrated next generation stack into B-Level build. Addresses improved system efficiency and packaging barriers listed above.
- Integrated a sorbent bed for removal of hydrogen sulfide (H₂S) from the reformat. Above-mentioned issue needs to be addressed:
 - Able to remove H₂S to <0.010 ppm.
- Enhanced the heat exchanger subsystems using a common footprint for each. Provides a more robust and cost-effective design.
- Launched the next generation endothermic reformer. Provides improved heat transfer and an improved cost due to reduced manufacturing complexity.

Introduction

Delphi's SOFC power system, installed on heavy-duty commercial trucks as an APU, addresses the growing concerns about emissions, fuel consumption, and noise. In the United States today, there are more than one million long-haul heavy-duty commercial trucks with sleeper cabs on the road. When drivers stop for their mandatory rest

FIGURE 2. Delphi Solid Oxide Fuel Cell Auxiliary Power Unit (A-Level Prototype) Installed on PACCAR Truck

periods or loading/unloading, they often leave their engines idling in order to heat/cool their sleeping areas and operate other vehicle systems. This idling practice is costly to the driver, the fleet owner, and harmful to the environment. The Environmental Protection Agency's SmartWay Transport Partnership estimates that each year, long duration idling of truck engines consumes approximately 960-million gallons of diesel fuel and emits 11 million tons of carbon dioxide, 180,000 tons of nitrogen oxide, and 5,000 tons of particulate matter into the air. In addition to the consumed fuel and emissions, idling trucks create elevated noise levels. The SOFC APU has the potential to decrease idling fuel consumption by up to 85%, reduce exhaust emissions below federal regulation emission standards, and decrease radiated noise levels to less than 60 dBA when compared to the truck's main engine.

As a result of the on-road demonstration under this project, Delphi will be able to present user profile data from its fleet customer. This data will reinforce the lab-generated data showing that use of a SOFC APU as an anti-idling solution will provide drivers and fleets with reduced fuel consumption as well as reduced emissions and noise. This demonstration should increase the overall awareness of SOFC APUs and provide positive momentum in preparing to commercialize this product.

Approach

Under this project, Delphi is pursuing a 3-phased approach to conduct its research. During Phase 1, Delphi, working with its truck manufacturer partner PACCAR, will establish the applications specifications and commercial requirements for a SOFC APU. Phase 2 work will focus on design verification and system testing (bench-top and on-vehicle). Phase 3 will include the demonstration of the SOFC APU on a heavy-duty Class 8 vehicle. The data collected during this phase will be analyzed and reported will respect to fuel consumption, emissions, and noise.

All Delphi facilities involved with this project are required to meet Delphi's stringent safety requirements which are aligned with the Safety Planning Guidance documentation specified by DOE.

Results

During this report period, Delphi has completed several of the tasks necessary to provide a road-ready SOFC APU to our fleet customer.

- Completed requirements document.
- Completed SOFC APU B-Level system design release.
- Completed SOFC APU system integration.
- Completed in-house subcomponent and system testing.
- Started SOFC APU system build. Scheduled to be delivered and installed on fleet customer truck during the third quarter of 2011.

Specific subcomponent and system development achievements are described in the Accomplishment section above.

Conclusions and Future Directions

Delphi continues to make significant progress towards introducing a production-intent SOFC APU for use by heavy-duty truck manufacturers, fleets, and drivers. This leading edge technology will provide users with the ability to run their hotel electrical loads during idling without the need to run their main truck engine or a diesel generator. As a result of using a SOFC APU, they will see reduced fuel consumption, reduced harmful emissions, and reduced noise.

Under this specific project, Delphi will next complete assembly and deliver its B-Level prototype SOFC APU to its fleet customer. After vehicle installation and fleet/

driver user training, the unit will be deployed in a real-world application. During this demonstration period, Delphi will be able to monitor the SOFC APU performance real time through a dedicated telematic connection.

Contract Number: EE-0000486

Subcontractors:

- Air Products & Chemicals, Inc., Allentown, PA (Fuel Project Partner)
- Altery Systems, Folsom, CA (PEM Fuel Cell Project Partner)
- Black & Veatch Corporation, Overland Park, KS (A&E Project Partner)
- Burns & McDonnell Engineering Co., Inc., Kansas City, MO (A&E Project Partner)
- Ericsson Services, Inc., Overland Park, KS (Deployment Management Project Partner)
- ReliOn, Inc., Spokane, WA (PEM Fuel Cell/A&E Project Partner)

Project Start Date: March 18, 2010

Project End Date: December 31, 2012

Relevance to the American Recovery and Reinvestment Act (ARRA) of 2009 Goals

Sprint, through this deployment effort, seeks to:

- Support the creation of new jobs.
- Maintain existing jobs.
- Bring proton exchange membrane (PEM) technology into the market which will foster job training opportunities.
 - Installation
 - Service
 - Repair

Relevance to the DOE-Fuel Cell Technologies' ARRA Project Goals

Through the successful deployment of this technology, it is expected that the following goals shall be achieved:

- Demonstrate the operational acceptance and financial viability of using PEM technology to support critical emergency power requirements:
 - Telecommunications.
 - Health care/life support systems.
 - Critical government operations.
- Expanded user community offers many positive market opportunities:
 - Increased demand prompts greater production volume – lowers unit cost.
 - Cross industry adoption spurs “services” growth (construction, maintenance, ancillary support) as more units are deployed – lower costs due to competition.
 - Fueling infrastructure is “pulled” into the market by true demand rather than being “pushed” into the market to support speculative potential.

Objectives

- Eliminate barriers to siting and permitting 72-hours of hydrogen fuel storage
- Eliminate barriers to re-fueling sites at the required level of performance
- Collect and analyze data sample to evaluate economic and operational metrics

Technical Barriers

Major barriers being addressed under our project are summarized as follows:

- Higher costs: initial capital cost, as well as operating expenditure (increased site lease costs to support code mandated hydrogen setbacks) than incumbent technology (diesel generator).

- Siting and permitting: due to variations in the applicable code requirements and versions recognized by the authorities having jurisdiction (AHJ), each market launch requires time with the local officials (building, fire) to help them understand the referenced codes and how Sprint interprets/complies with code requirements.
- Fueling infrastructure: this project deploys a new model for stationary hydrogen fuel cells, relying upon an on-site refillable medium pressure storage solution rather than the low pressure hydrogen cylinder exchange model. Our project partner, Air Products, has invested in a small fleet of transport vehicles to deliver bulk compressed hydrogen to small, geographically diverse, remote cell sites.

Technical Targets and Milestones

The following performance targets and associated milestones have been set for this project.

- Install 260 additional PEM fuel cells for backup power by end of December, 2012.
 - California – 100 units
 - Connecticut – 30 units
 - New Jersey – 65 units
 - New York – 65 units
- Retrofit a total of 70 existing Low Pressure Hydrogen Storage Systems with the new Medium Pressure On-Site Refillable Hydrogen Storage Solution in the following states:
 - California
 - Louisiana
 - Texas

Accomplishments

- Completed the required documentation for National Environmental Policy Act (NEPA) clearance and received the requested comprehensive Categorical Exclusion on May 12, 2011.
- Thus far, our team has conducted site surveys at 583 candidate sites to support new PEM deployments at 260 locations.
- A total of 283 of the 583 candidates were removed from consideration for a variety of reasons during Phase 1 (site survey, entitlement review).
 - Space constraints within the cell site compound (real estate and setbacks).
 - Access restrictions for hydrogen fueling vehicle.
- An additional 37 candidates “fell out” during Phase 2 (site acquisition) due to:
 - Cost.
 - Zoning issues.

- Commissioned the first new unit on 05/11/2011 in Alloway, NJ. As of 06/30/2011, a total of 32 new PEM fuel cells have been commissioned into service.
- Expect to have 194 new PEM fuel cells commissioned by the end 2011.

Introduction

The relevance of this project to the goals of ARRA of 2009 is threefold. First, Sprint seeks to support the creation of new jobs, as well as maintain existing jobs, to successfully complete this deployment effort. Second, Sprint intends to spur economic activity through the positive impact to various industries and service providers at all levels of the supply chain. And finally, Sprint is confident that this investment in PEM hydrogen fuel cells, to provide emergency power to our critical wireless network facilities, will truly benefit our nation’s long-term economic growth.

Approach

After reviewing the Code Division Multiple Access (CDMA) Network Site Inventory, a master candidate site list was created based upon the restoration priority of the facility, and whether or not the site was equipped with a fixed generator. Sprint focused on specific markets to exploit the site’s proximity to the hydrogen distribution facility (within 200 miles), as well as to concentrate on market clusters to minimize site acquisition, siting/permitting, installation, commissioning, and training expenditures. In addition, this cluster approach helps to minimize costs associated with the maintenance of a PEM spare parts inventory. Finally, this concentration permits a consistent presentation to the local building officials, which in turn helps to clarify applicable code (Uniform Building Code, National Fire Protection Association, etc.) interpretations. In theory, all of these efforts should help to facilitate a rapid, safe, and successful deployment in the market.

Our Hydrogen Safety Plan (HSP) was submitted to DOE on 07/13/2010. On 01/18/2011, feedback from the Safety Panel team at DOE was received. Additional work is required on the HSP to ensure that the issues identified by DOE are satisfactorily addressed prior to resubmission. In reality, modifications to the HSP were put on the “back burner” as our efforts to demonstrate progress on new PEM deployments required our team’s full time and attention – now targeting delivery of the revised HSP to DOE by end of calendar year 2011.

A NEPA comprehensive Categorical Exclusion was secured on May 12, 2011.

Results

At long last, Sprint has successfully commissioned the first of many PEM fuel cells equipped with the Medium Pressure, Refillable On-Site, Hydrogen Storage Solution. Since the initial installation under this DOE/ARRA funded project on May 11, 2011, a total of 32 systems have been brought into service (as of 06/30/11). These installations, coupled with our original stand-alone deployment effort (243 systems in the 2005–2007 timeframe), provide a grand total of 275 PEM fuel cells providing backup power for critical cell site locations on the Sprint Network. When the planned 260 new and 70 retrofits (fuel storage converted from low pressure tanks to the medium pressure refillable solution) are completed, we will

have more than doubled the number of sites in our Network with emergency power provided by PEM fuel cells. Figure 1 provides the deployment schedule for this project.

To date, a total of 583 sites have been evaluated to determine if the cell site location is suitable for new PEM deployment or, if equipped with a PEM today, can it support the use of the new hydrogen fuel storage solution. Figure 2 provides a summary of the various reasons so many sites are dropped from consideration following the completion of Phase 1 activities.

Once the candidate site makes it through Phase 1, sites can be dropped from consideration during Phase 2. Figure 3 provides a summary of the various reasons a site

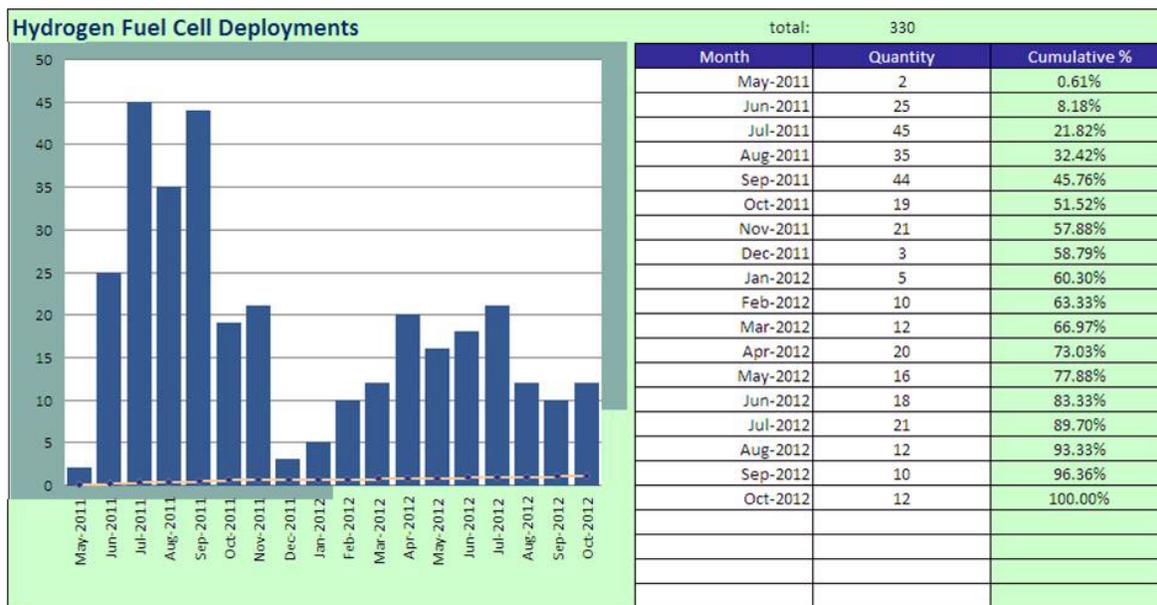

FIGURE 1. EE0000486 Deployment Schedule

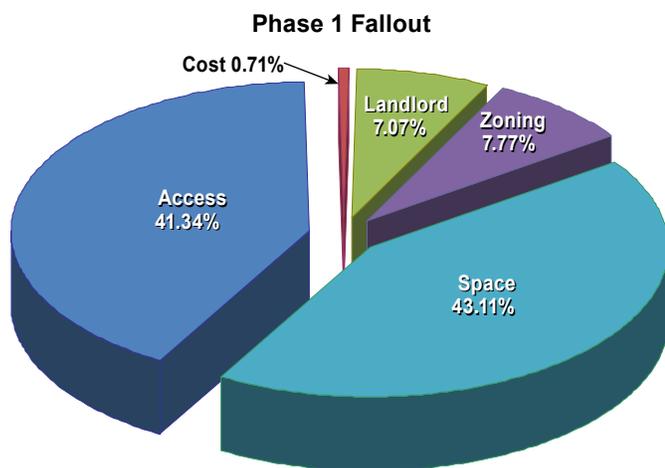

FIGURE 2. Phase 1 (Site Survey/Entitlement Review) Fallout Summary

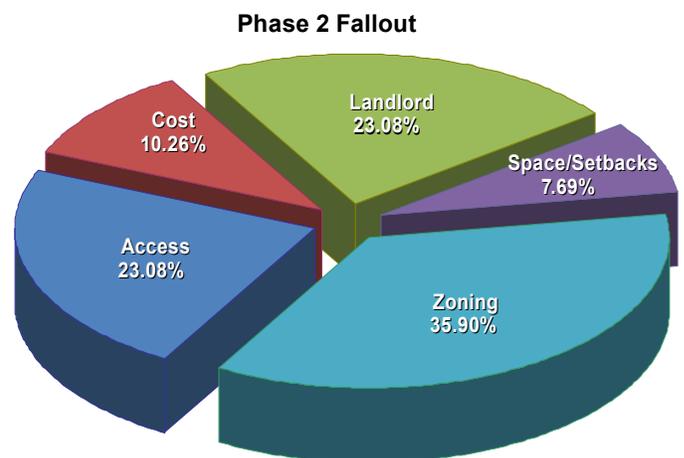

FIGURE 3. Phase 2 (Site Acquisition/Zoning) Fallout Summary

can be dropped at this stage of deployment. Interestingly, it appears that the education of property owners (landlords, tower aggregators), municipal officials, and/or the zoning board might permit more sites to remain in consideration.

Conclusions and Future Directions

We recognized going into this project that the fallout rate for candidate sites would be in the 40% range due to the limited amount of space available in the cell site compound. Limited real estate, in the case of PEM deployment, can be a double edged sword. There may be physical space to permit the placement of the equipment on-site, however, code mandated setback distances may or may not be able to be supported at the facility. Without uniform AHJ recognized hydrogen/fire codes, it appears that PEM deployment will continue to require more time/effort/money to deploy versus the incumbent diesel generator solution.

XII.6 PEM Fuel Cell Systems Providing Backup Power to Commercial Cellular Towers and an Electric Utility Communications Network

Contract Number: DE-EE0000487

Subcontractors:

- Fortune Wireless, Indianapolis, IN
- Betacom, Inc., Pompano Beach, FL
- United Commercial Real Estate Services, Inc., Lake Mary, FL
- Peek Site-Com, Inc., Auburn, CA
- Jeffrey Rome and Associates, Newport Beach, CA
- Vertical Horizons Contracting, Lincoln, NE
- Telecom, Tower and Power, LLC, Romulus, MI
- Front Range Wireless, Centennial, CO
- Air Products and Chemicals, Inc. (APCI), Allentown, PA

Project Start Date: August 1, 2009

Project End Date: December 31, 2011

Objectives

- Install 189 fuel cell cabinets (385 fuel cell systems total) with 72-hour capacity as back-up power equipment for communications sites in use by Pacific Gas & Electric (PG&E), a California utility, and as critical emergency reserve power for cell sites operated by AT&T.
- Demonstrate that fuel cells are a reliable source of clean back-up power for key communications facilities.
- Transform the market within PG&E and AT&T by moving beyond limited demonstration sites to wider deployments

Relevance to the goals of the American Recovery and Reinvestment Act (ARRA) of 2009, and to the goals of U.S. DOE Fuel Cell Technologies' (FCT) ARRA project for accelerating the commercialization and deployment of fuel cells and fuel cell manufacturing, installation, maintenance, and support services.

This project will contribute to achievement of the DOE's objectives for ARRA projects in general, and the FCT projects in particular:

- Create direct and indirect jobs in seven regions across the continental United States, throughout the supply chain.
- Train and deploy installers of fuel cell systems.
- Increase the number of commercially available fuel cell systems.
- Generate volume for fuel cell supply chain.
- Create and deploy new refillable hydrogen storage for stationary hydrogen fuel cells.
- Create and deploy new hydrogen delivery model for stationary hydrogen fuel cells.
- Expand practical user operating experiences.
- Validate performance.

Technical Barriers (Market Transformation Barriers)

This project addresses the barriers to market transformation for stationary backup fuel cell equipment:

- Site Selection: myriad considerations in site selection factor into the adoption of fuel cells for backup equipment.
- Permitting: multiple stakeholders, including authorities having jurisdiction, fire officials, building officials, and landlords, all have varying perspectives and reference a variety of non-harmonized standards for permitting.
- Fueling infrastructure: this project deploys a new model for stationary hydrogen fuel cells, relying on a refillable storage module, in place of the historically used cylinder exchange model. This requires the development of a fueling infrastructure that can deliver bulk compressed hydrogen to small, geographically diverse, remote sites.

Technical Targets and Milestones

- Survey candidate sites to identify 189 sites for installation.
- Secure all permitting, site acquisition, lease amendments, etc. to proceed with installations.
- Manufacture, ship, install, and commission 189 stationary fuel cell sites (385 systems).
- Collect data on operation, fuel service, and maintenance.

Accomplishments

- Reviewed database records of an additional 82 candidate AT&T sites for a total of 736 to down-select sites based on the feasibility of fuel cell installation and on-site refueling accessibility.

- Performed physical site surveys at an additional 60 candidate AT&T sites for a total of 520 to further down-select sites based on the feasibility of fuel cell installation and refueling accessibility.
- Generated and delivered 65 unique quotes for additional services needed to support the 180 AT&T sites to be constructed and 132 replacement quotes for site acquisition and installation services corresponding to replacement sites for 66 previously cancelled sites.
- Processed an additional 178 unique purchase orders (for a total of 487) from AT&T Procurement for site acquisition (SAC) services, fuel cell installation services, and supplemental shelter direct air cooling equipment and installation services.
- Initiated the SAC process (leasing, zoning/planning, permits, etc.) on an additional 64 AT&T sites for a total of 252 sites.
- Completed the SAC process for an additional 116 AT&T sites for a total of 132 sites.
- Fabricated, integrated, and delivered fuel cell equipment (48 cabinets = 120 systems) for an additional 48 AT&T sites for a total of 180 sites, and hydrogen storage modules (HSMs) for an additional 111 AT&T sites for a total of 180 sites.
- Constructed and commissioned an additional 101 sites (227 systems) for a total of 109 sites (244 systems) and provided hand-off to AT&T.
- Generated an additional unique scope of work for one replacement PG&E site used to replace a site that was unable to be successfully acquired by PG&E's real estate group.
- Constructed and commissioned all nine PG&E sites (9 systems) and provided hand-off to customer.

Introduction

Market transformation is best achieved by reaching a critical mass in the market that significantly raises awareness and direct experience of the value proposition. With the assistance of this project, ReliOn is installing 385 fuel cell systems (within 189 cabinets) into the telecommunications and utility networks at AT&T and PG&E for backup power, across nine states, combined with the deployment of a refillable stationary HSM unit and the accompanying refueling logistics platform for 180 AT&T sites. These are real-world, tangible changes to the market resulting in the use of hydrogen based systems to harden critical communications networks.

Approach

ReliOn's approach begins with the basic research needed to identify viable candidate sites and then narrow down the list in order to focus efforts on the most viable

and critical sites that can be installed and refueled successfully, ensuring that these assets will remain viable for decades. This work is primarily performed by ReliOn personnel. The next task is to secure rights to perform the construction through the use of SAC vendors who structure the leasing and permitting packages to prepare the sites for construction. ReliOn utilizes third parties who are skilled in this profession and will remain part of the program until all SAC activities have been completed.

As a site clears the SAC process, it is then constructed (typically within one month) and brought on-line as a fully functional back-up power system. Installation construction is performed only after the SAC vendor has secured the installation and operating rights for each site. ReliOn utilizes third parties to perform installation construction, yet retains the roles of project management and supervision. ReliOn partnered with an established hydrogen provider, APCI an industry expert in hydrogen storage and delivery for the development and production of the HSM. Once the sites are installed, fueled and operational, they are monitored remotely for data collection. ReliOn personnel collect and report fuel cell operational data to the DOE/National Renewable Energy Laboratory (NREL). The use of both ReliOn and third party resources maximizes the effectiveness of the project, creates or retains jobs across a breadth of companies and regions, and delivers the maximum amount of infrastructure for the given financial investment.

Results

To date, ReliOn has completed the site qualification stage for the entire project. This has allowed for the successful initiation of SAC activities on all target sites, plus a few reserve sites as contingencies for sites that may fail to complete the SAC process due to unforeseen circumstances. Since project inception, 66 AT&T sites and one PG&E site have been cancelled and successfully replaced. SAC has been completed on a total of 132 AT&T sites to date with 54 presently undergoing the SAC process. ReliOn has installed 253 fuel cell systems at 118 sites to date (244 systems at 109 sites for AT&T and nine systems at nine sites for PG&E) with 14 more AT&T sites (34 systems) presently in the construction phase and nine more sites (21 systems) pending construction. This ongoing process of SAC approval and site construction has resulted in the continuous need for labor and has secured multiple jobs. PG&E performed the SAC of their nine sites using their internal real estate and legal department resources, and all PG&E construction is now complete.

Figure 1 shows an AT&T site located in Michigan which has just completed the initial fill of the HSM during the commissioning process. The fill was performed using the newly developed single-axle 'straight truck.' This vehicle makes the fueling of certain remote sites feasible and more efficient due to its reduced size, improved mobility, and higher service pressure in comparison to legacy tube trailers pulled by semi-tractors.

FIGURE 1. Completed AT&T Site in MI Showing ‘Straight Truck’

Figure 2 shows a close up of an AT&T site located in Colorado undergoing the initial fill of the HSM during the commissioning process. The leftmost cabinet is the fuel cell equipment enclosure with an adjacent six-cylinder hydrogen storage cabinet. The larger cabinet to the right with the doors open and red cylinders in view is the HSM. The HSM is connected to the system in parallel with the six-cylinder hydrogen storage cabinet, and contains the majority of the fuel capacity.

This project deploys fuel cell systems within eight states as shown in Figure 3, though it promotes jobs and supports business in other states which are the home bases of various subcontractors. AT&T presently has systems operating in all eight states. As a California utility, all of PG&E’s systems are located within California and they are all presently operational.

FIGURE 2. Fueling of HSM at Completed AT&T Site in CO

As discussed earlier, the SAC activity is a primary task that must be completed before fuel cell system installation construction can commence. Each site’s respective SAC activity concludes with an official “notice to proceed” package which is the trigger for the call out of fuel cell equipment from the warehouse for delivery to the site and delivery of the work release package for the installation contractor(s). ReliOn discovered during the past year that the original schedule for the completion of SAC was too optimistic and that the SAC process in general takes twice as long as originally expected. These SAC delays have resulted in the inability to start and complete the construction of sites per the original deployment schedule milestones. Figure 4 shows the project schedule for the completion of AT&T site construction. Note the adjustment made to the schedule goals at the end of the first quarter of 2011. This course correction was put in place to readjust the schedule to conform to the reality of the situation created by the delays in the SAC process. A no-cost contract extension was requested by ReliOn and received from the DOE, extending the contract to December 31, 2011.

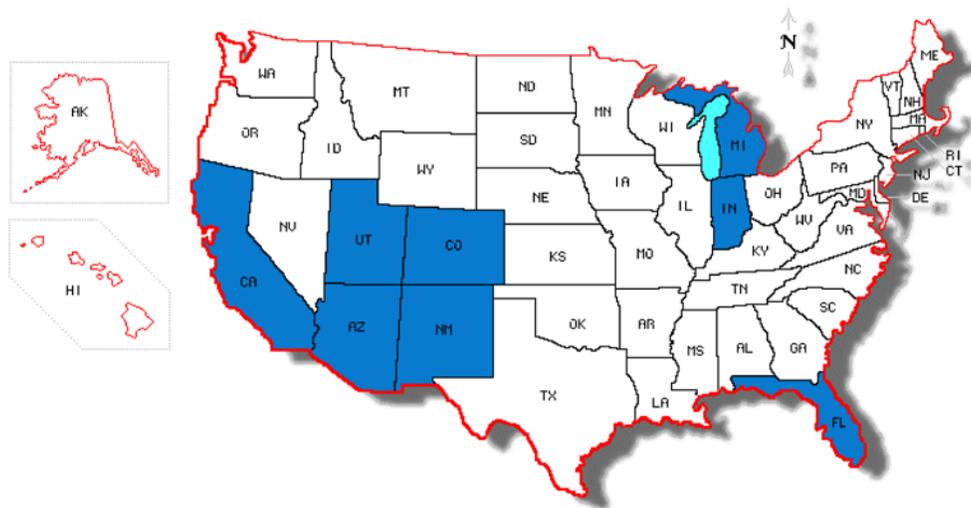

FIGURE 3. States Benefiting from the AT&T/PG&E Regional Fuel Cells

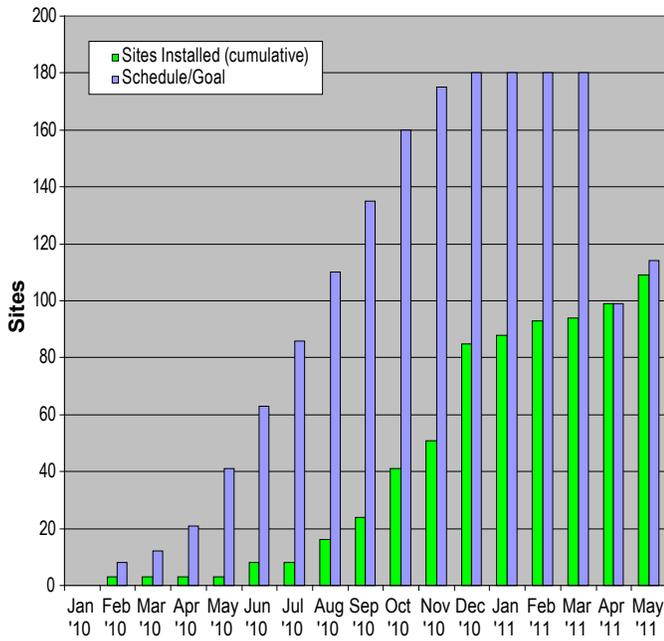

FIGURE 4. SAC Initiation Progress Through 6/1/2011 for 180 AT&T Sites

Conclusions and Future Directions

During the past year of effort, ReliOn learned that the drop out rate of sites undergoing SAC was higher than expected. One in three sites has been cancelled due to circumstances beyond ReliOn’s control, resulting in a cycle of additional replacement site reviews, physical site

surveys, quote and purchase order modifications, and re-submittal of sites into the SAC process. This additional activity has added cost and stretched ReliOn resources dedicated to the project. It was also discovered that the SAC process takes longer on average than originally estimated by subcontractors. Where two months was originally considered an adequate gestation period for the process, it was discovered that six months is a more typical average time to acquire the site.

Tasks planned for the remainder of the project through the end of 2011 include:

- Complete the SAC process for all remaining sites within the project:
 - This activity includes working with the local authorities having jurisdiction to educate them on hydrogen safety, fuel cells, and codes & standards to resolve any questions/issues that arise during SAC.
- Construct all remaining sites and commission the equipment for hand-off to the customer/end-user.
- Obtain and report operational data to fulfill the DOE/NREL data reporting requirement.
- Continue to generate and provide all DOE reports per the required schedule.

E-mail: Sara.Dillich@ee.doe.gov

Subcontractor

Pacific Northwest National Laboratory, Richland, WA

Project Start Date: August, 2009

Project End Date: Project continuation and direction determined annually by DOE

Accomplishments

- Expanded the NREL Fleet Analysis Toolkit (NRELFAT) to include MHE, backup power, and stationary power data processing, analysis, and reporting.
- Published three deployment focused Composite Data Products (CDPs), updated on a quarterly basis.
- Published two cycles of technical focused CDPs (42 CDPs for MHE and 10 CDPs for backup power data) and hundreds of detailed data results were shared with individual data providers, updated bi-annually. Key performance results include operation time, fill time, maintenance, reliability, safety, usage patterns, and durability.
- Created a website and maintained it for all published results and presentations.

Introduction

The DOE has designated more than \$40 million in American Recovery and Reinvestment Act (ARRA) funds for the deployment of up to 1,000 fuel cell systems. This investment is enabling fuel cell market transformation through development of fuel cell technology, manufacturing, and operation in strategic markets where fuel cells can compete with conventional technologies. The strategic markets include MHE, backup power, stationary power, and portable power, where the majority of the deployed systems are in the MHE and backup power markets. NREL is analyzing operational data from these key deployments to better understand and highlight the business case for fuel cell technologies and report on the technology status.

Approach

Data (operation, maintenance, and safety) are collected on site by the project partners for the fuel cell system(s) and infrastructure. NREL receives the data quarterly and stores, processes, and analyzes the data in NREL's Hydrogen Secure Data Center (HSDC). The HSDC is an off-network room with access for a small set of approved users. An internal analysis of all available data is completed quarterly and a set of technical CDPs are published every six months. The CDPs are aggregated data across multiple systems, sites, and teams in order to protect proprietary data and summarize the performance of hundreds of fuel cell systems and thousands of data records. A review cycle is completed before the publication of CDPs. The review cycle includes Detailed Data Products (DDPs) of individual system and site performance results provided to the individual data provider. DDPs also identify the individual contribution

Objectives

- Independent technology assessment in real-world operation conditions focusing on fuel cell system and hydrogen infrastructure.
- Leverage data processing and analysis capabilities developed under the Fuel Cell Vehicle Learning Demonstration.
- Support market growth through reporting on technology status to key stakeholders and analyses relevant to the markets' value proposition.
- Study fuel cell systems operating in material handling equipment (MHE), backup power, portable power, and stationary power applications; includes up to 1,000 deployed fuel cell systems.

Technical Barriers

This project addresses the technical barrier of commercialization of fuel cells in key early markets and the associated performance capabilities and benefits.

Technical Targets

- Deployment of up to 1,000 fuel cell systems: By December 2010, 557 systems were delivered and 483 of those systems were in operation.

to CDPs. NRELFAT is an internally created tool for data processing and analysis structured for flexibility, growth, and applications. Analyses are created for general performance studies as well as application or technology specific studies.

Results

NREL created NRELFAT to efficiently process and analyze large amounts of data for the study of performance at the system, fleet, application, and across applications levels. Because the analysis results are created with multiple purposes and expected audiences, the set of results is varied and comprehensive of many aspects of the hydrogen and fuel cell deployments.

One result topic is where the systems are deployed and what some of the site specifications are. Each marker on the map in Figure 1 identifies the application, system(s) location, and deployment size at that site. There are 96 backup power sites (with more sites to be determined in the next few months), but most have only one to three systems installed at the site. There are eight MHE sites, but some of these sites have around 100 systems operating. Fuel cell systems are deployed in many regions of the United States, expanding the user base familiar with hydrogen and fuel cell technologies.

In the set of results published in the spring of 2011, 308 MHE systems were analyzed and had accumulated 307,433 operation hours in less than one year. Each site has a different system and operational conditions for the fuel cell MHEs. Figure 2 highlights the variation in average daily fuel cell system operation hours by fleet. (A fleet is a collection of same class MHEs and a site may have multiple fleets.) The range of average daily operation hours is between two and eight hours.

Refuel time is a critical performance metric for the operation of fuel cell MHEs and benefit over competing technologies. Figure 3 depicts the fueling rate for 38,795 hydrogen fills with an average of 0.33 kg/min. The inset graph highlights that all of the sites averaged very similar fill rates. The average fill time was just under two minutes per fill.

The backup power deployments have a very different operating metric than the fuel cell MHE sites. In certain locations a backup system may not operate because of a grid outage for many months. Figure 4 depicts the number of attempted and successful starts by calendar month as well as conditioning starts. A conditioning start is an automated operation for regular system checks and hydration after long periods of no operation (typically a month). Conditioning starts account for 59% of the start attempts and 408 out of 409 starts were successful.

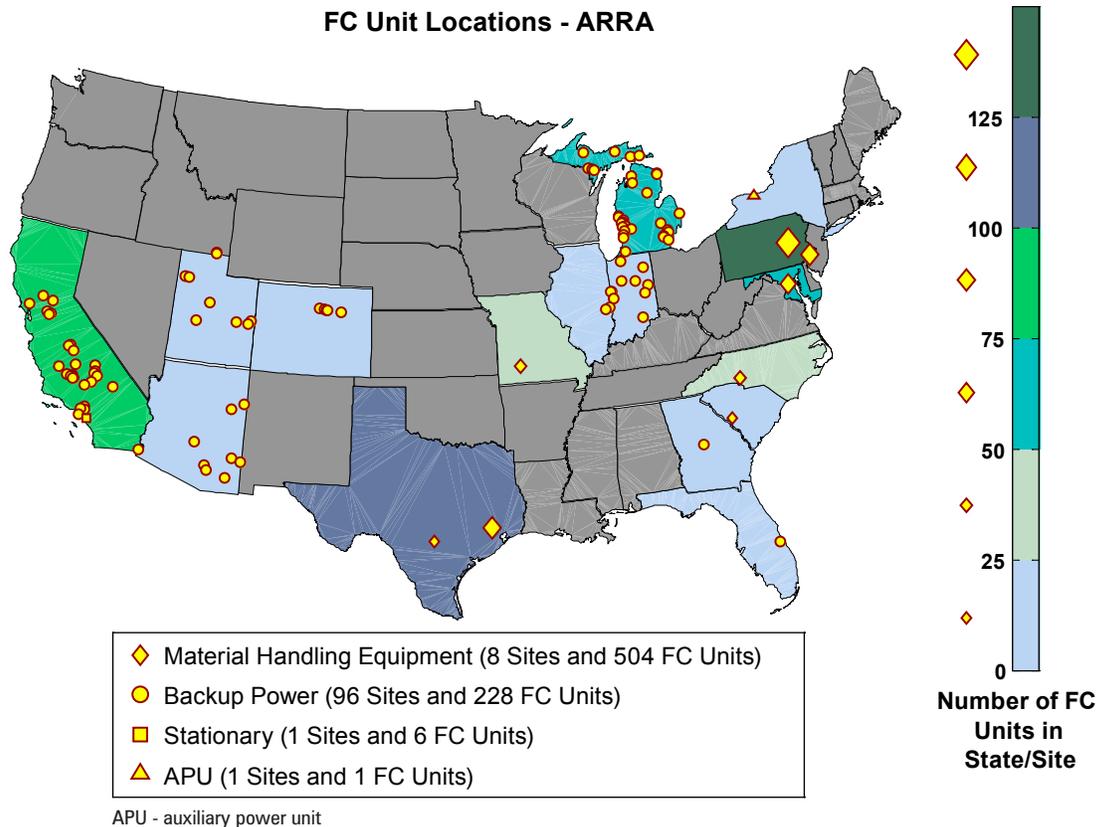

FIGURE 1. Fuel Cell (FC) System Locations by Application and Deployment Size

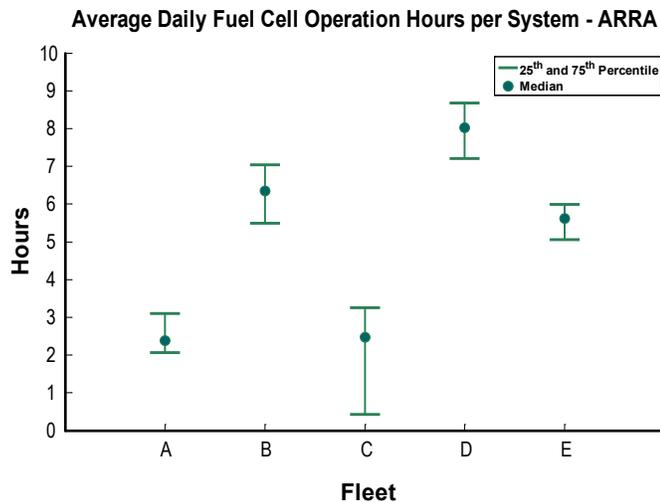

FIGURE 2. Average Daily Fuel Cell System Operation Hours by Fleet

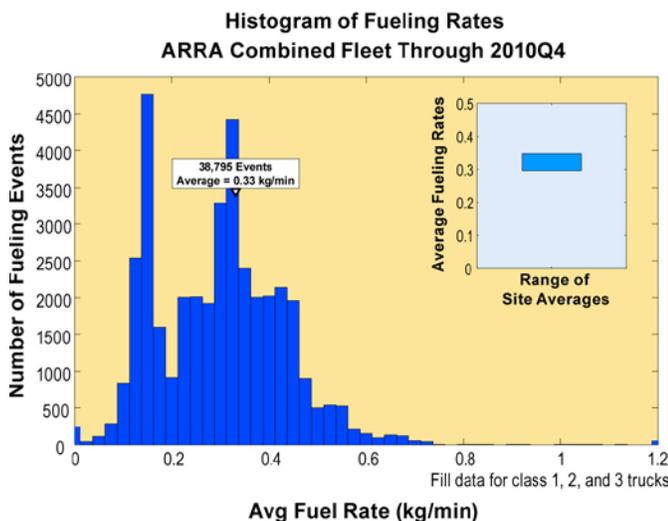

FIGURE 3. MHE Histogram of Fueling Rates and Range of Site Average Fueling Rates

Conclusions and Future Direction

This project has seen rapid deployment of hundreds of fuel cell systems in markets where the technology is ready to compete with incumbent technologies. Many aspects of the deployment and operation are analyzed and reported on via the CDPs. The CDPs have highlighted the magnitude of operation in operation hours (over 307,600 hours combined) and hydrogen fills (over 38,800 combined). These systems are demonstrated the capability to meet end user demands while learning lessons to integrate into future products and the operations are proving to be safe.

Planned future work includes:

- Quarterly publication of deployment focused CDPs.

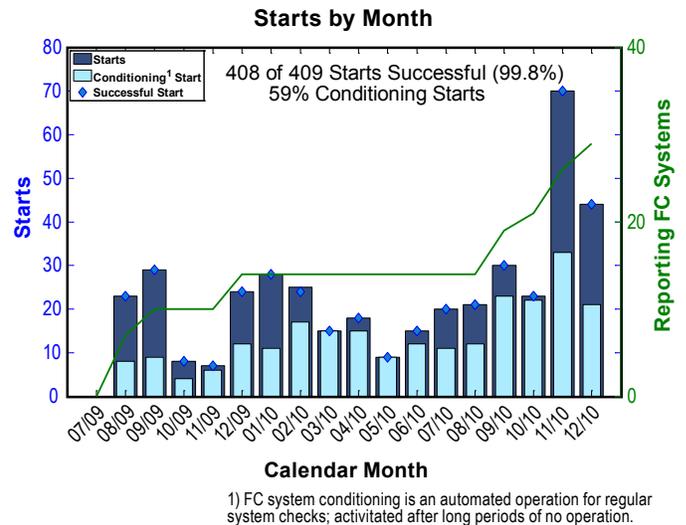

FIGURE 4. Count of Backup Power Attempted and Successful Starts by Month

- Bi-annual publication of technical focused CDPs and DDPs.
- Technical monitoring and coordination of hydrogen safety panel reviews and site visits.
- Quarterly analysis of operation, maintenance, and safety data for fuel cell systems and hydrogen infrastructure.
- Collaboration with key stakeholders to identify valuable analyses for technology status updates and metrics important to the value proposition.

Contract Number: DE-EE0000489

Subcontractors:

- Airgas Southwest, San Antonio, TX
- Airgas Merchant Gases, Bozrah, CT
- Parkway Systems, San Antonio, TX

Project Start Date: September 1, 2009

Project End Date: August 30, 2011

Technical Barriers Addressed

- Reliability of technology (fuel cell systems and hydrogen generation, storage, and compression equipment) used in a highly demanding materials handling application and environment.
- Durability of fuel cell systems and hydrogen generation, storage, and compression equipment.
- Quantification of costs associated with operation and maintenance of all equipment.
- Proper safety planning and safe operation of all equipment.
- Safe hydrogen use indoors, in high-throughput, high-density distribution center.
- Obtaining necessary permitting for motive fuel cell power units and hydrogen generation and refueling equipment, requiring collaboration of authorities having jurisdiction (AHJs), the industrial truck fleet manager, the environmental health and safety (EHS) coordinator, and the industrial truck equipment provider.
- Obtaining insurance coverage for the use of all equipment.
- Availability of hydrogen generated on-site from a steam methane reformer.

Objectives

Validate DOE market transformation activities by demonstrating:

- Fuel cell-powered forklifts operating in a high-usage, highly transient mobility application.
- An on-site natural gas-based hydrogen generation and refueling station as a precursor to future distributed automotive fuel cell refilling stations.

Relevance to the American Recovery and Reinvestment Act (ARRA) of 2009 Goals:

- Stimulate use of emerging technologies – additional investment by H-E-B is anticipated, without ARRA funding.
- Develop jobs and job skills (manufacturing, product development, repair and maintenance) in clean energy growth industries.
- Develop product and performance improvements to make fuel cells and hydrogen refueling equipment commercially viable.

Technical Targets and Milestones

- Install 14 proton exchange membrane (PEM) fuel cells in Class II forklift trucks and operate for two years in produce and dry goods grocery distribution centers.
- Generate hydrogen on-site from natural gas to support forklift truck fleet and maintain 100% availability of hydrogen at the pump through combination of hydrogen generator and hydrogen tube trailer backup.

Accomplishments

- Built a permanent PowerTap hydrogen refueling station and introduced 14 PowerEdge systems into 24/7 service at a grocery distribution center owned and operated by a nationally recognized industry leader.
- Generated 11,002 kg of hydrogen on site through July 2011.
- Maintained >99% hydrogen availability at the pump for forklift refueling.
- Logged 21,899 operating hours on 14 PowerEdge fuel cell power units through July 2011.
- Demonstrated 10% productivity gain associated with fuel cells vs. lead acid batteries.

- Redesigned the next generation PowerEdge system for greater performance and reliability.
- Obtained field data that has been fundamental in next-generation PowerEdge fuel cell system and PowerTap hydrogen refueling equipment designs.
- Provided extensive data on PowerTap and PowerEdge performance to the National Renewable Energy Laboratory.

Introduction

H. E. Butt Grocery Company, Inc. (H-E-B) is a privately-held supermarket chain with 310 stores throughout Texas and northern Mexico. The company agreed to convert a portion of its lift truck fleet to fuel cell power to verify the value proposition and environmental benefits associated with the technology. H-E-B management believes that fuel cell forklifts can help alleviate several issues in its distribution centers, including truck operator downtime associated with battery changing, truck and battery maintenance costs, and reduction of grid electricity usage. It is also interested in other uses of hydrogen produced on site in the future, such as for auxiliary power units used in tractor-trailers in its fleet.

Currently, the H-E-B distribution center operates a total of approximately 300 Class II reach trucks and 700 Class III pallet jacks over two work shifts, for a total of 20 hours per day. There are three temperature zones in the facility, ranging from dry goods at ambient temperature, to refrigerated goods at 34°F (1°C), to freezer goods at -13°F (-25°C). The PowerEdge units provided are powering Class II fork lift trucks that were designed for use with 1,000 Ah lead acid batteries, and are capable of operation in both the ambient and refrigerated goods temperature zones of the San Antonio facility. Data collected from this initial installation will enable H-E-B to make economic decisions on expanding the fleet of PowerEdge and PowerTap units in the company.

Approach

In order to verify compatibility of the PowerEdge fuel cell power units with H-E-B's forklift fleet, information was gathered regarding truck make and model and usage profile within H-E-B's grocery and produce distribution centers. Power monitoring of the trucks was undertaken in order to confirm that the duty cycle was achievable with the PowerEdge product, and to determine the number of units that could be supported by a PowerTap system producing 50 kg/day of hydrogen. We determined that 14 PowerEdge systems could be supported by the PowerTap production capacity, which is how that number of forklifts was chosen for repowering.

A site-specific installation plan was prepared that detailed where all hydrogen generation, compression, storage, and dispensing equipment would be placed. As the site plan was being developed, the PowerTap and PowerEdge equipment was manufactured and delivered to the H-E-B facility, where it was installed in accordance with required codes and standards. Upon final sign-off from both the local AHJ and the insurance carrier, the forklift fleet was deployed for operation in the grocery and perishable sections of the distribution center alongside forklifts operating with standard lead-acid batteries. Side-by-side operation allows H-E-B to assess the value associated with the PowerEdge and PowerTap products compared with conventional battery technology.

Results

As presented in Table 1 below, the build of all 14 PowerEdge systems and the PowerTap hydrogen refueling equipment was complete as of October 30, 2009. In parallel, Nuvera application engineers, working with H-E-B facility engineers, created site-specific service and installation plans. Nuvera and H-E-B's EHS coordinator also developed a comprehensive safety plan, which was reviewed by a DOE-appointed safety panel over the last 6 months.

TABLE 1. Work Breakdown Schedule

Task #	Project Milestones	Milestone Completion Date			
		Original Planned	Revised Planned	Actual	Percent Complete
1	Build	10/30/09		10/30/09	100%
2	Site Plan	10/30/09		10/30/09	100%
3	Deployment	11/30/09	2/28/10	2/28/10	100%
	Go/No-Go: 2 PowerEdges Productivity Trial; certify passing of FAT; permitting and approvals	11/30/09	12/30/09	12/30/09	100%
4	Confirm Value Proposition	5/31/11	5/31/11		100%
5	Final Testing	8/31/11	8/31/11		0%
6	Project Management & Reporting	8/31/11	8/31/11		96%

FAT – factory acceptance test

A total of 60 H-E-B forklift operators received hydrogen and fuel cell training. Based on the agreed site plan, Nuvera identified and provided basic training to two local fuel cell service personnel, who work for an H-E-B wholly-owned subsidiary, Parkway Systems. The role of the Parkway service provider is to keep the PowerEdge systems operational by providing a fast response to diagnosing system faults and repairing the units. This type

of service includes scheduled preventive maintenance, basic troubleshooting, and the repair or replacement of non-safety critical items. Nuvera's Customer Care group provides spare parts, training, data analysis, and more complex field support, including troubleshooting and repairs of safety-critical items (high pressure, high voltage). Nuvera also trained and qualified three Airgas personnel (two from Airgas Southwest, the local service provider, and one from Airgas Bozrah, responsible for 24-hour hydrogen system monitoring) for Tier 1 service of the PowerTap hydrogen generator and the PowerTap hydrogen station (compression, storage, dispensing).

During this process, all relevant codes and standards were identified, and working with the AHJ and the H-E-B insurance carrier, all permits were obtained for site construction, installation, and operation.

The deployment process began upon establishing the final site plan and was completed on February 28, 2010.

H-E-B Grocery Total Power Solution for Fuel Cell-Powered Material Handling Equipment

In May 2010, H-E-B conducted an analysis to determine whether any productivity benefits were realized in association with the fuel cell forklift conversion. H-E-B concluded that the fleet was 10% more productive than it was running on lead acid batteries, a combination of the elimination of the battery changing task and the improved performance of the trucks. The equipment maintenance supervisor also noted a marked decrease in motor controller failures on lift trucks running on fuel cells, a consequence of the elimination of voltage sag associated with batteries. As part of the project conclusion, H-E-B is quantifying the value proposition benefits.

PowerEdge Fuel Cell Systems

Over the first three months of operation, H-E-B reported an increase in productivity of 10% for the PowerEdge systems compared to forklifts running on batteries.

As part of the ongoing program, Nuvera provides data to the National Renewable Energy Laboratory using jointly-agreed data templates. Information collected during the course of daily operations includes the following:

- Power pack fault code indication
- Service notifications
- Operating status
- Fuel cell run time
- Fuel cell power
- Total kWh energy produced
- Total kWh energy consumed

The full fleet of 14 fuel cell-powered trucks was operational until July 2010, when hot weather combined with several other factors caused reliability of the systems

to suffer and to negatively impact operations. Since these issues were disruptive to H-E-B's operations, Nuvera scaled back the number of units in service. We identified the root causes of the problems and determined the required corrective actions. The solutions were implemented on four operational PowerEdge fuel cell units in early October, 2010. The solutions were validated, and Nuvera implemented them on the remaining 10 PowerEdge units and introduced them back into service in December 2010.

PowerTap Hydrogen Generation and Refueling Systems

Figure 1 shows the amount of hydrogen provided at the site from the PowerTap system and from the back-up tube trailer. The percent of hydrogen supplied by PowerTap is also indicated. Note that reduced usage from July through November reflects reduced fuel cell fleet size.

Conclusions and Future Directions

- Our next generation PowerEdge system design will address performance and reliability issues that have surfaced in this demanding application. Specifically, our new product for the reach truck application will:
 - Replace the 'ultrabattery' with a lithium ion battery, which our analysis indicates will improve battery life to be on par with the remainder of the system (>20,000 hours).
 - Incorporate an 'auto-on' feature to turn the PowerEdge unit on in the event that the truck is being used but the operator has neglected to also start the fuel cell system.
 - Incorporate a fuel cell stack with approximately twice the power rating at end of life (10 kW) as the current system.
 - Incorporate more robust power circuits.
 - Improve controls to extend stack life.
- Similarly, the next generation PowerTap design will incorporate improvements required for satisfactory operation in a demanding materials handling application, including the following:
 - A solution to avoid water pump damage associated with superheated steam.
 - A controls upgrade to avoid reformate compressor wear.
 - A higher capacity desulfurizing system to avoid sulfur breakthrough.
- H-E-B has determined that fuel cells are their preferred motive power source for reach trucks. They have already set aside the budget required for expanding the fleet by purchasing 28 additional PowerEdge units, pending a demonstration of acceptable performance of our next generation higher power system. The increased fleet size will require the addition of two PowerTap systems.

Contract Number: DE-EE0000482

Subcontractors:

- Plug Power Inc., Latham, NY
- Air Products and Chemicals, Inc., Allentown, PA

Project Start Date: October 1, 2009

Project End Date: September 30, 2013

- Creating jobs at Air Products to design, install and commission hydrogen storage and fueling equipment.
- Creating jobs at Air Products to deliver hydrogen to the FedEx Freight Springfield, MO facility.
- Training FedEx Freight lift truck operators in hydrogen safety, fueling procedures and fuel cell operation.
- Training FedEx Freight lift truck maintenance personnel to service fuel cells.
- Improving the overall economic efficiency of material handling operations.

This project advances the DOE Fuel Cell Technologies' ARRA project goals of accelerating the commercialization and deployment of fuel cells and fuel cell manufacturing, installation, maintenance, and support services by demonstrating:

- Safe and reliable operation of hydrogen storage and fueling equipment and fuel delivery.
- Reliable and efficient operation of hydrogen fuel cells.
- Economic and environmental advantages of fuel cells over batteries.
- Practical operation and maintenance of fuel cells.

Objectives

The objectives of this project are to:

- Convert an entire fleet of 35 class-1 electric lift trucks to hydrogen fuel cells at the FedEx Freight facility in Springfield, MO.
- Demonstrate the safe and reliable operation of hydrogen-fueled material handling equipment (MHE).
- Demonstrate the economic benefits of conversion to hydrogen fuel cell-powered MHE.
- Demonstrate operator acceptance of hydrogen fuel cell-powered MHE.
- Provide a cost-effective and reliable hydrogen fuel supply.
- Spur further lift truck fleet conversions to hydrogen fuel cells.
- Establish a proving ground for hydrogen fuel cell-powered MHE.

Relevance to the American Recovery and Reinvestment Act (ARRA) of 2009 Goals

This project advances the goals of the ARRA of 2009 to create new jobs, save existing jobs, and spur economic activity and investment in long-term economic growth by:

- Creating jobs at Plug Power to design, build and commission the fuel cell power units.

Technical Barriers

This project addresses the following technical barriers to the use of fuel cell powered lift trucks:

- Repair frequency of hydrogen fuel cells.
- Cold weather operation of hydrogen fuel cells.
- Cold weather operation of hydrogen storage and fueling equipment.

Technical Targets and Milestones

The technical targets and milestones of this project include:

- Installing hydrogen storage and fueling equipment by May 2010.
- Developing a hydrogen safety plan by May 2010.
- Commissioning 35 class-1 power units by December 2009.
- Completing startup and training by June 2010.
- Starting operation and evaluation by July 2010.

Accomplishments

The accomplishments of this project include:

- Commissioning 35 GenDrive class-1 power units by December 2009.

- Commissioning hydrogen storage and fueling equipment by June 2010.
- Completing all fueling, operation and maintenance training by June 2010.
- Purchasing and commissioning an additional five GenDrive class-1 power units in December 2010 (without DOE funding).
- Determining that problems with air-actuated valves during cold-weather operation of the hydrogen storage and fueling system were caused by excessive moisture in the air supply.
- Modifying lift trucks to prevent drive-offs that damaged the hydrogen fueling hose.
- Logging over 48,000 hours of fuel cell operation by the end of July.
- Purchasing 18,300 kilograms of hydrogen by the end of July.
- Monitoring operating costs and reliability of 40 GenDrive power units (ongoing).
- Demonstrating 30-60% more operating hours per repair for fuel cells compared to propane lift trucks between July 2010 and February 2011.

Introduction

The purpose of this project is to demonstrate that hydrogen fuel cells are a safe and economical alternative to batteries for powering electric lift trucks. The primary barriers to widespread use of hydrogen fuel cells for material handling equipment are concerns about the safety of hydrogen storage and fueling equipment, operating costs for fuel and maintenance, and the long-term reliability of fuel cells.

Approach

This project evaluates the safety and economics of using hydrogen fuel cells to power a fleet of 35 class-1 electric lift trucks at the FedEx Freight facility in Springfield, MO. FedEx Freight supplies the lift trucks, Plug Power supplies the GenDrive fuel cell power units and Air Products supplies the hydrogen fuel and the hydrogen storage and fueling equipment. The fuel cell equipment is maintained by FedEx Freight personnel with assistance from Plug Power and Air Products personnel when necessary. Plug Power and Air Products also assisted FedEx Freight in developing a comprehensive hydrogen safety plan.

Previous FedEx Freight field trials with a limited number of GenDrive power units demonstrated productivity gains and improved performance compared to battery-powered lift trucks. The lift truck fleet conversion in Springfield is

expected to demonstrate improved operational efficiencies and help the environment by reducing greenhouse gas emissions and the use of toxic battery materials. A successful demonstration of these advantages at the Springfield facility could lead to additional fleet conversions at other FedEx Freight facilities.

The Hydrogen Safety plan has been completed and reviewed. The changes to the safety plan are in the process of being made.

The National Environmental Policy Act forms were submitted to the DOE. There are no outstanding National Environmental Policy Act requirements. The project was granted a categorical exclusion determination prior to the project commencing.

Results

To date, this project has successfully demonstrated the safe and economical operation of 40 GenDrive class-1 power units and associated hydrogen storage and fueling equipment. The power units have accumulated over 48,000 hours of operation and consumed 18,300 kilograms of hydrogen.

A few problems occurred during cold-weather operation. Problems with air-actuated valves in the hydrogen storage and fueling system were caused by excessive moisture in the air supply. Problems with the power units were resolved by adding thermal insulation to sensitive components.

Fueling hoses were damaged on two occasions when lift trucks were driven away from the fueling station while the fueling hoses were still attached to the lift truck. The lift trucks were subsequently modified to prevent them being driven while the fueling hoses were attached.

FedEx Freight found that the fuel cell-powered lift trucks at the Springfield facility had 63% more hours of operation per repair (115.2 hours/repair) compared to similar propane-powered lift trucks at the South Dallas facility (70.5 hours/repair) and 30% more hours of operation per repair compared to propane lift trucks at all FedEx Freight facilities (88.3 hour/repair).

Figure 1 shows a breakdown of the types of fuel cell repairs. Instrumentation and control (35%), cooling (16%), hydrogen (13%), and humidification (11%) systems accounted for 75% of all repairs. Figure 2 shows that 74% of all repairs required less than two hours of labor. Figure 3 shows that 35% of all fuel cell repairs to date have occurred during the first 100 hours of operation.

Based on the favorable operational results with the initial 35 power units, FedEx Freight purchased an additional five power units in December 2010 without DOE funding.

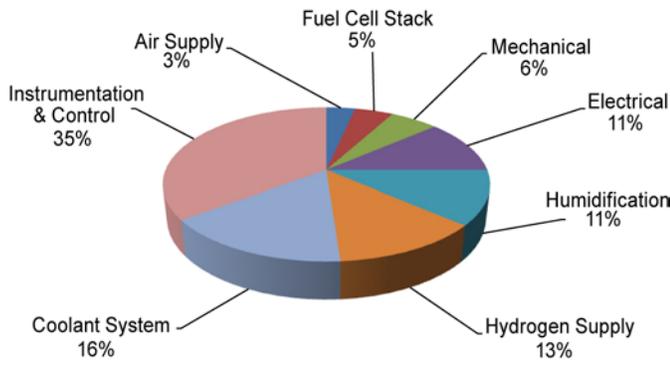

FIGURE 1. Types of Fuel Cell Repairs

FIGURE 2. Labor Hours for Fuel Cell Repairs

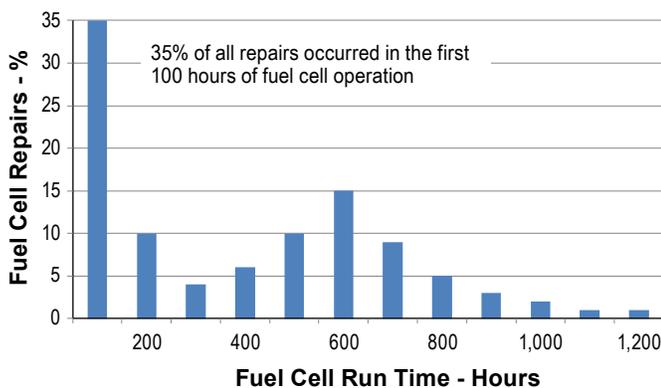

FIGURE 3. Fuel Cell Repair Frequency vs. Run Time

Conclusions and Future Directions

Based on our operational experience to date, hydrogen fuel cells appear to be a safe and economical alternative to batteries for electric lift trucks. We will continue to monitor the long-term costs and reliability of hydrogen fuel cells by:

- Providing ongoing operational and maintenance support for the GenDrive power units and the hydrogen storage and fueling equipment.
- Collecting data from the power units to evaluate performance, operability and safety.
- Collecting data from the hydrogen storage and fueling equipment to evaluate performance, operability and safety.
- Resolving cold-weather operation problems with air-actuated valves in the hydrogen storage and fueling equipment.
- Working with Plug Power to resolve cold-weather operation problems with fuel cells.

FY 2011 Publications/Presentations

1. Held an official ribbon-cutting ceremony in October 2010 to inaugurate the hydrogen fuel cell project at the FedEx Freight service center in Springfield, MO.
2. Delivered an American Recovery and Reinvestment Act merit review presentation in Washington, DC in May 2011.
3. Contributed a synopsis of project progress to the DOE's *Energy Empowers* blog.

Contract Number: DE-EE0000485

Subcontractors:

- Plug Power Inc., Latham, NY
- Air Products and Chemicals, Inc., Allentown, PA
- Big-D Construction, Salt Lake City, UT

Project Start Date: October 1, 2009

Project End Date: September 30, 2013

Relevance to the American Recovery and Reinvestment Act (ARRA) of 2009 Goals

This project advances the goals of the American Recovery and Reinvestment Act (ARRA) of 2009 to create new jobs, save existing jobs, and spur economic activity and investment in long-term economic growth by:

- Creating jobs at Plug Power to design, build and commission the fuel cell power units.
- Creating jobs at Air Products and Big-D Construction to design, install and commission hydrogen storage and fueling equipment.
- Creating jobs at Air Products to deliver hydrogen to the Sysco Houston facility.
- Training Sysco Houston lift truck operators in hydrogen safety, fueling procedures and fuel cell operation.
- Training Sysco Houston lift truck maintenance personnel to service fuel cells.
- Improving the overall economic efficiency of material handling operations.

This project advances the DOE-Fuel Cell Technologies' ARRA project goals of accelerating the commercialization and deployment of fuel cells and fuel cell manufacturing, installation, maintenance, and support services by demonstrating:

- Safe and reliable operation of hydrogen storage and fueling equipment and fuel delivery.
- Reliable and efficient operation of hydrogen fuel cells.
- Economic and environmental advantages of fuel cells over batteries.
- Practical operation and maintenance of fuel cells.

Technical Barriers

This project addresses the following technical barriers to the use of fuel cell-powered lift trucks:

- Safe and reliable hydrogen use in a high-throughput distribution center.
- Fuel cell use in sub-zero temperatures.
- Fuel cell lifetime and reliability.

Technical Targets and Milestones

The technical targets and milestones of this project include:

- Installing hydrogen storage and fueling equipment by December 2009.
- Developing a hydrogen safety plan by May 2010.

Objectives

The objectives of this project are to:

- Convert a fleet of 79 class-3 electric lift trucks to hydrogen fuel cells at the Sysco Houston facility (including seven temporary rental units and 25 sub-zero temperature units).
- Demonstrate the safe and reliable operation of hydrogen-fueled material handling equipment (MHE).
- Demonstrate the economic benefits of conversion to hydrogen fuel cell-powered MHE.
- Demonstrate operator acceptance of hydrogen fuel cell-powered MHE.
- Demonstrate the operation of hydrogen fuel cells in sub-zero temperatures.
- Provide a cost-effective and reliable hydrogen fuel supply.
- Spur further lift truck fleet conversions to hydrogen fuel cells.
- Establish a proving ground for hydrogen fuel cell-powered MHE.

- Commissioning 79 class-3 power units by February 2010.
- Completing startup and training by February 2010.
- Starting operation and evaluation by March 2010.

Accomplishments

The accomplishments of this project include:

- Commissioning hydrogen storage and fueling equipment by December 2009.
- Commissioning 79 GenDrive class-3 power units by February 2010.
- Completing all fueling, operation and maintenance training by February 2010.
- Training over 100 Sysco personnel in the safe use and fueling of hydrogen fuel cells.
- Commissioning 26 GenDrive class-2 power units by April 2010 (these power units are not included in the scope of this project).
- Logging 12 months and over 300,000 hours of fuel cell operation by February 2011.
- Completing 31,000 fueling operations, consuming 38,760 pounds (17,618 kilograms) of hydrogen by February 2011.
- Demonstrating the successful operation of 25 class-3 power units in sub-zero temperatures.
- Monitoring operating costs and reliability of all GenDrive power units (ongoing).

Introduction

The purpose of this project is to demonstrate that hydrogen fuel cells are a safe and economical alternative to batteries for powering electric pallet jacks and lift trucks. The primary barriers to widespread use of hydrogen fuel cells for MHE are concerns about the safety of hydrogen storage and fueling equipment, operating costs for fuel and maintenance, and the long-term reliability of fuel cells.

Approach

This project will evaluate the safety and economics of using hydrogen fuel cells to power a fleet of 26 class-2 and 79 class-3 electric lift trucks at the Sysco Houston facility. Sysco Houston will supply the lift trucks, Plug Power will supply the GenDrive fuel cell power units, Air Products and Big-D Construction will supply the hydrogen storage and fueling equipment, and Air Products will supply the hydrogen fuel. The equipment will be maintained by Sysco Houston personnel with assistance from Plug Power and Air Products personnel when necessary. Plug Power and

Air Products will also assist Sysco Houston in developing a comprehensive hydrogen safety plan.

Sysco Houston and Plug Power will monitor the operation and maintenance of the power units and the hydrogen storage and fueling equipment over the duration of the project. This information will be reported to the DOE and National Renewable Energy Laboratory quarterly and summarized annually.

Results

This project has successfully demonstrated the safe and economical operation of 26 class-2 and 72 class-3 power units and associated hydrogen storage and fueling equipment. The class-2 power units were not included in the funding for this project. Seven of the original 79 power units were rentals and have been returned to Plug Power. Twenty-five of the class-3 power units were modified to operate in sub-zero temperatures.

The fuel cell power units accumulated over 300,000 hours of operation and consumed 13,500 kilograms of hydrogen by February 2011. The current cost of hydrogen fuel is approximately the same as the cost of electricity to charge lead-acid batteries but Sysco is saving nearly \$100,000 per year in fewer man-hours spent refueling fuel cells compared to swapping batteries. The lift truck operators also appreciate the improved performance of fuel cells compared to lead-acid batteries.

Sysco and Plug Power have been monitoring the type and frequency of fuel cell repairs. Figure 1 shows the distribution of repairs by class and Figure 2 shows the mean time between repairs (MTBR) distribution by class. To date, no conclusions have been drawn to explain the differences in repair statistics between the class-2 and class-3 power units. However, Sysco has changed the way they maintain pallet jack and lift truck power sources from reactive maintenance with lead-acid batteries to preventative maintenance with the hydrogen fuel cells.

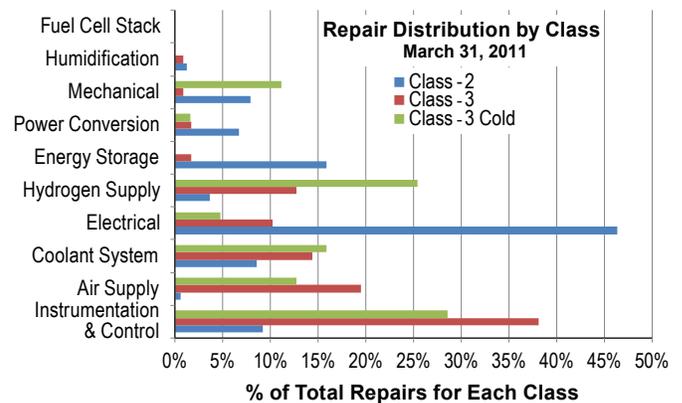

FIGURE 1. Repair Distribution by Class

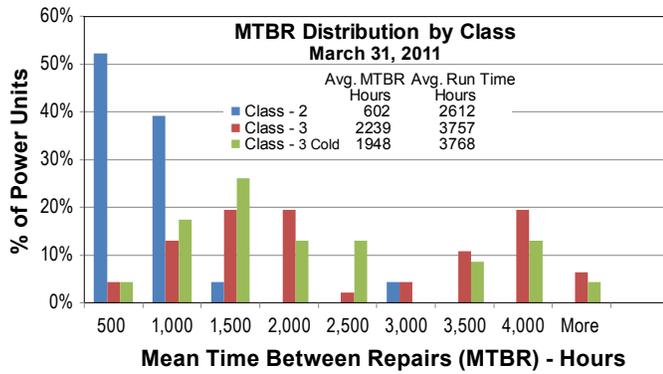

FIGURE 2. MTBR Distribution by Class

Conclusions and Future Directions

Based on the proven reliability and safety of current hydrogen fuel cell operations at Sysco Houston, Sysco’s future directions include:

- Ongoing operational and maintenance support for power units and hydrogen storage and fueling equipment.
- Ongoing data collection from power units and hydrogen storage and fueling equipment.
- Planning to replace approximately 1,000 lead-acid batteries with 500+ fuel cells at seven additional sites over the next 24 months.
- Committed to fuel cell fleet conversions at Philadelphia, San Antonio, Long Island and Northeast Redistribution Center facilities.

- Considering additional fuel cell fleet conversions for Los Angeles, San Francisco, and Boston facilities.
- Supporting the conversion to fuel cells to help reduce the overall costs of fuel cell power units and hydrogen fuel.
- Helping other Sysco facilities develop hydrogen safety plans.

FY 2011 Publications/Presentations

1. Sysco hosted several open houses to showcase the fuel-cell-powered lift truck fleet, which subsequently became the subject of various local news articles and television news stories.
2. Scott Kliever delivered a presentation at the 2010 Fuel Cell Seminar and Exposition in San Antonio, TX, October 18–20, 2010.
3. Sysco and Plug Power prepared a case study of the Sysco Houston distribution center.
4. Scott Kliever was interviewed for the April 2011 cover story in *Materials Handling & Logistics* magazine titled *Making Sense of Power Sources*.
5. Scott Kliever delivered an American Recovery and Reinvestment Act merit review presentation in Washington, D.C. in May 2011.
6. Scott Kliever delivered a presentation at the Hydrogen + Fuel Cells 2011: International Conference and Exhibition, May 15–18, 2011, in Vancouver, BC, Canada.

- Plug Power Inc., Latham, NY
- Air Products, Allentown, PA
- Linde North America, Murray Hill, NJ

Project Start Date: October 1, 2009

Project End Date: September 30, 2013

- Creating jobs at Plug Power to design, build and commission the fuel cell power units.
- Creating jobs at Air Products and Linde to design, install and commission hydrogen storage and fueling equipment.
- Creating jobs at Air Products and Linde to deliver hydrogen to GENCO facilities.
- Training lift truck operators in hydrogen safety, fueling procedures and fuel cell operation.
- Training lift truck maintenance personnel to service fuel cells.
- Improving the overall economic efficiency of material handling operations.

This project advances the DOE Fuel Cell Technologies' ARRA project goals of accelerating the commercialization and deployment of fuel cells and fuel cell manufacturing, installation, maintenance, and support services by demonstrating:

- Safe and reliable operation of hydrogen storage and fueling equipment and fuel delivery.
- Reliable and efficient operation of hydrogen fuel cells.
- Economic and environmental advantages of fuel cells over batteries.
- Practical operation and maintenance of fuel cells.

Objectives

The objectives of this project are to:

- Convert 357 electric-drive fork lift trucks from batteries to fuel cell power units in five large distribution centers and manufacturing facilities.
- Demonstrate the safe and reliable operation of hydrogen-fueled material handling equipment (MHE).
- Demonstrate the economic benefits of conversion to hydrogen fuel cell-powered MHE.
- Demonstrate operator acceptance of hydrogen fuel cell-powered MHE.
- Provide a cost-effective and reliable hydrogen fuel supply.
- Spur further lift truck fleet conversions to hydrogen fuel cells.
- Establish a proving ground for hydrogen fuel cell-powered MHE.

Relevance to the American Recovery and Reinvestment Act (ARRA) of 2009 Goals

This project advances the goals of the American Recovery and Reinvestment Act (ARRA) of 2009 to create new jobs, save existing jobs, and spur economic activity and investment in long-term economic growth by:

Technical Barriers

This project addresses the following technical barriers to the use of fuel cell-powered lift trucks:

- Represents a change in technology, which is often met with reluctance.
- Uncertain power unit reliability due to lack of widespread performance data.
- Safety and expense of hydrogen and fueling equipment.
- Difficulty in obtaining permits and approvals for hydrogen fueling stations.

Technical Targets and Milestones

The class and number of power units and the hydrogen supplier for each GENCO location are shown in Table 1.

The status of project milestones for deploying fuel cell power units and hydrogen storage and fueling equipment are shown in Table 2.

TABLE 1. Power Unit Distribution and Hydrogen Suppliers

Power Unit	Wegmans Pottsville PA	Whole Foods Landover MD	Coca-Cola Charlotte NC	Sysco Philadelphia PA	Kimberly-Clark Graniteville SC	Total

Accomplishments

The accomplishments of this project include:

- Commissioning hydrogen storage and fueling equipment at all sites (see Table 2 for completion dates).
- Commissioning power units at all sites (see Table 2 for completion dates).
- Completing fueling, operation and maintenance training at all sites.
- Operating power units at all sites (see Table 2 for starting dates).
- Some power units at Wegmans have accumulated over 5,000 hours of operation.

Introduction

The purpose of this project is to demonstrate that hydrogen fuel cells are a safe and economical alternative to lead-acid batteries for powering electric-drive lift trucks. The primary barriers to widespread use of hydrogen fuel cells for material handling equipment are concerns about the safety of hydrogen storage and fueling equipment, operating costs for fuel and maintenance, and the long-term reliability of fuel cells.

Approach

This project will evaluate the safety and economics of using hydrogen fuel cells to power over 350 lift trucks at five GENCO facilities. GENCO will supply the lift trucks, Plug Power will supply the GenDrive fuel cell power units, Air Products and Linde will supply the hydrogen storage and fueling equipment and the hydrogen fuel. The equipment will be maintained by GENCO personnel with assistance from Plug Power, Air Products and Linde personnel when necessary.

GENCO and the subcontractors will monitor the operation and maintenance of the power units and the hydrogen storage and fueling equipment over the duration of the project. This information will be reported to the DOE and National Renewable Energy Laboratory quarterly and summarized annually.

Results

This project has successfully demonstrated the safe and economical operation of 300 class 1, 2 and 3 fuel cell power units and associated hydrogen storage and fueling equipment at five GENCO facilities. An additional 57 power units will be added at the Sysco Philadelphia facility by April 2012.

Some of the fuel cell power units at the Wegmans facility have accumulated over 5,000 hours of operation. GENCO and Plug Power have been monitoring the type and

frequency of repairs on these power units. Figure 1 shows the repair frequency of these power units and Figure 2 shows the types of power unit repairs.

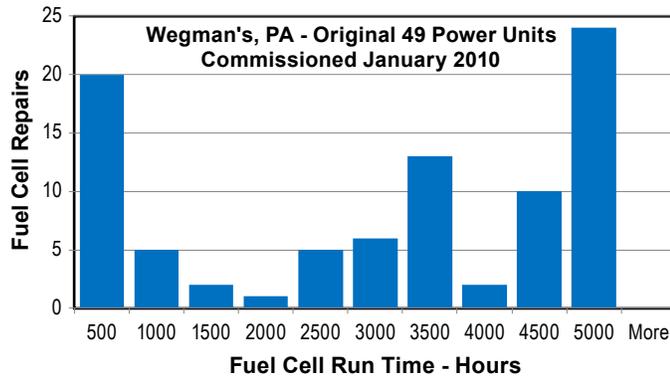

FIGURE 1. Fuel Cell Repair Frequency

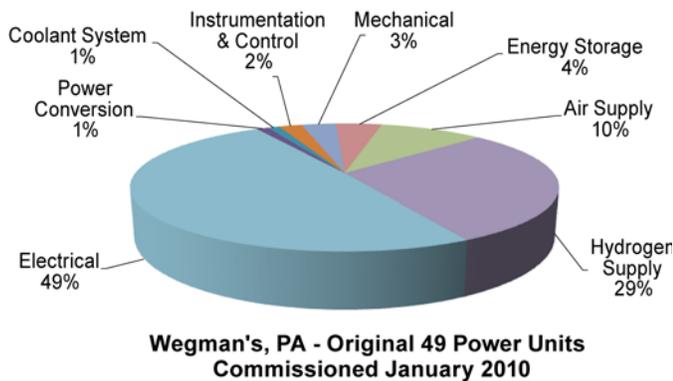

FIGURE 2. Types of Fuel Cell Repairs

Conclusions and Future Directions

Based on the proven reliability and safety of current hydrogen fuel cell operations at GENCO facilities to date, future directions include:

- Ongoing operational and maintenance support for power units and hydrogen storage and fueling equipment.
- Ongoing data collection from power units and hydrogen storage and fueling equipment.
- Helping to reduce the overall costs of fuel cell power units and hydrogen fuel by supporting the conversion to fuel cells at other locations.

Fiscal Year 2011 Publications/Presentations

1. Key federal and state government officials, leaders in sustainable energy solutions and executives from Kimberly-Clark, GENCO ATC, Plug Power and Air Products attended a ribbon-cutting ceremony and technology demonstration at the Kimberly-Clark site on February 11, 2011.
2. GENCO delivered an American Recovery and Reinvestment Act merit review presentation in Washington, DC in May 2011.

Contract Number: DE-EE0000480

Subcontractor:
University of California, Irvine (UCI), Irvine, CA

Project Start Date: October 1, 2009
Project End Date: September 30, 2012

- **Performance:** Improve system performance and efficiency so the device's value is observed by the customer.

FY 2011 Accomplishments

- Home site assessments were performed in California.
- Three systems shipped to UCI and infrastructure installed at UCI for site preparation.
- Stack life in Latham systems went from an average of 1,500 hours to 3,800 hours.

Introduction

The high-temperature proton exchange membrane (PEM) fuel cell system is the culmination of a nine-year technology development effort that has produced numerous technical innovations. Plug Power began exploring the application and feasibility of high-temperature PEM technology in 1999 with the creation of an “Alpha” system to demonstrate technical feasibility. It was quickly evident that the high-quality heat produced and the resulting system simplification would make this a preferred technology for μ CHP applications—one that held the promise of a commercial, grid-connected, stationary fuel cell product that provided a cost benefit to the end user. Indeed, high-temperature PEM technology offers a unique value proposition over low-temperature PEM systems in applications where heat utilization is required. In a low-temperature system, the quality of the heat supplied may be insufficient to meet consumer needs and comfort requirements, so peak heaters or supplemental boilers may be required. The higher operating temperature of the polybenzimidazole (PBI) membrane technology allows the fuel cell to produce heat for applications that demand higher temperatures required to obtain desirable heat transfer rates without additional equipment.

GenSys Blue is a pre-commercial, 5 kW, natural gas-fueled product that is technically ready to be demonstrated in real-world residential and light commercial installations. The key risks for this technology lie in supply chain readiness and stack material supply. Further refinements in the areas of PBI technology, stacks, advanced controls, and fuel reforming will be made as Plug Power continues to understand technology development needs and product development requirements for this fuel cell system.

Fiscal Year (FY) 2011 Objectives

- Demonstrate the durability and economic value of GenSys Blue.
- Verify its technology and commercial readiness for the marketplace.

Relevance to American Recovery and Reinvestment Act of 2009 and DOE Fuel Cell Technologies Goals

- The project deploys GenSys Blue, natural-gas fueled, micro-combined heat and power (μ CHP) fuel cell units that provide economic savings and environmental benefits for residential and light commercial users.
- The project maintains five U.S., high-tech jobs in New York State and provides work for U.S. suppliers and field service contractors.

Technical Barriers

- **Durability:** Push system durability to commercially viable levels. Critical subsystems and components include stack, burner, reformer, pumps, air delivery module, and controls/software.
- **Cost:** Drive cost down through design simplification, low-cost manufacturing and supply chain.

Approach

Plug Power is executing a demonstration project that will test multiple units of its high-temperature PEM fuel cell system in residential and light commercial μ CHP applications in New York and California. The specific objective of the proposed demonstration project is to understand the durability of GenSys Blue, and thereby verify its path to technology and commercial readiness for the marketplace. In the proposed demonstration project, Plug Power, in partnership with the National Fuel Cell Research Center (NFCRC) at UCI, and Sempra, will execute two major tasks:

- **Task 1:** Internal durability/reliability fleet testing. Six GenSys Blue units will be built and will undergo an internal test regimen consisting of typical residential load profiles to estimate failure rates.
- **Task 2:** External customer testing. Four GenSys Blue units will be installed and tested in real-world residential and light commercial end-user locations in California. (Note: this task was to originally install six systems, but after discussions with DOE was reduced to four)

Results

Plug Power's employees are supporting this effort maintaining an internal and external reliability fleet of GenSys Blue natural gas power systems. Researchers at the NFCRC at UCI are also providing resources to test and understand this system. Commercial suppliers are delivering stack, reformer and balance-of-plant components.

The NFCRC at UCI continued its dynamic modeling efforts of the GenSys Blue system this year. The team has had very good success in modeling the individual subsystems and reactors. Modeling the complete system, however, has proven to be a very difficult task due to the numerical stiffness of the problem. These numerical difficulties arise because this system contains many thermal, energy, and

material interconnections. Those interconnections cause the numerical problem to become large and its solution to become slow and unwieldy. The team is exploring methods to help speed up a solution.

Sempra Energy and members of the Plug Power team have begun to finalize the list of sites for the California fleet and have begun preliminary planning and design. The sites are evaluated based on ease of installation, match between customer load profile and system capability, ability to service a given customer site, flexibility of customer in the case of system outage, and anticipated value to the customer.

The team continued long-term reliability testing on the internal fleet installed in Plug Power labs (Figure 1). Table 1 shows that since commissioning in January 2010 the fleet has logged over 30,000 hours of stack operation producing over 50 MWhrs of electricity and 417 MWhrs of heat; averaging over 30% electrical efficiency and over 85% thermal efficiency. During this time the overall, uncorrected, CHP product availability of the fleet was 73%. This compares to 85% from last quarter and is the result of non-operating systems due to the discontinuity in stack material supply. The corrected CHP availability remains at approximately 91%.

In addition, three systems were installed in the NFCRC at UCI. A significant amount of infrastructure work was required to prepare the installation. The installation of heat rejection systems, wiring, piping, and exhaust ducts was completed recently. Plug Power completed two stacks in May 2011 and installed them in the systems in June 2011. The three units at UCI are now running; two systems are in CHP mode and one system is in heat-only operation until a stack is available for installation.

In the past year, the team has seen improvements in stack life. Plug Power has implemented some key advances in stack materials and assembly to more than double stack life. Stack life went from an average of 1,500 hours to 3,800 hours. One stack sample ran in system operation

Totals	-	29530	23203	35729	50511	417389	-	-
Average	-	4922	3867	5955	8419	69565	0.70	0.73

for an excess of 6,000 hours. These improvements have been attributed to plate and membrane electrode assembly advances.

Figure 2 shows the breakdown in failure types within the Latham, NY fleet. Although stack life receives a lot of attention because of the cost, we have seen a higher

frequency of nuisance failures in the thermal management module (TMM), air delivery module (ADM), and controls module (CM). These reliability issues are correctable and less costly than stack replacement but still need to be addressed in order to move toward commercial readiness.

Conclusions and Future Directions

The internal reliability fleet has continued to generate data during this past year. The California systems are just coming online and will help us understand the California requirements better. Availability of stack materials remains to be a pacing item and we continue to try to improve the external supply chain and internal manufacturing methods.

Continued progress will help us achieve the following milestones:

- Completion of the full system model by NFCRC.
- Ship and install remaining systems in California.
- Maintain the reliability fleet, capturing requirements from the California market.
- 2nd Go/No-Go decision.
- Perform economic analysis.

Reliability Fleet Failure-Module Allocation (18479 cumulative system hours) as of 9/21/2010

E-mail: Reginald.Tyler@go.doe.gov

Contract Number: DE-EE0000488

Project Start Date: June 1, 2009
Project End Date: December 31, 2012

Introduction

Since 2001, Plug Power has installed more than 800 fuel cell systems worldwide. Plug Power's prime power systems have produced approximately 6.5 million kilowatt hours of electricity and have accumulated more than 2.5 million operating hours. Intermittent or backup power products have been deployed with telecommunications carriers, government and utility customers in North and South America, Europe, the United Kingdom, Japan and South Africa. The low-temperature GenSys fuel cell system provides remote, off-grid and primary power where grid power is unreliable or nonexistent. Built reliable and designed rugged, low-temperature GenSys delivers continuous or backup power through even the most extreme conditions (-5°C to 40°C, altitudes up to 1,000 m, and remote locations). Coupled with high-efficiency ratings (25%-30% depending on the operating point), low-temperature GenSys reduces operating costs making it an economical solution for prime power requirements. Field trials at telecommunication and industrial sites in India, U.S., Asia, and Europe have demonstrated the advantages of fuel cells—lower maintenance, fuel costs and emissions, as well as longer life—compared with traditional internal combustion engines.

Objectives

- Increase distributed power generation.
- Improve reliability and efficiency of mission critical backup power.
- Decrease fossil fuel dependencies for power generation.

Relevance to American Recovery and Reinvestment Act of 2009 and DOE Fuel Cell Technology Goals

- Demonstrate market viability and increase pull of hydrogen and fuel cell systems within our government customers/partners.
- Deploy 20 GenSys hybrid, hydrogen start/liquefied petroleum gas (LPG) or natural gas units that provide economically viable backup power in excess of 72 hours.
- Maintain seven United States (U.S.), high-tech jobs in New York State and provide work for U.S. suppliers and field service contractors.

Accomplishments

- The Robins Air Force Base, Georgia has been developed through detailed engineering and is currently under construction.
- As of June 2011 several engineering and environmental buildings were assessed and considered to be in need of backup power at Ft. Irwin, California.

Approach

This project will leverage technology from Plug Power's Gensys product line to create a reliable power source that starts fast and runs as long as fuel is available. The project tasks and status are shown below.

Cost Analysis and Commercialization Study	100% complete
Site Planning and Applications Engineering	50% complete
Site Specific Engineering Development	30% complete
System Builds and Factory Testing	90% complete
Field Deployment Go/No-Go	Post-installation
Fleet Operation and Managed Services	Not started
Project Closeout	Not started
Program Management	45% complete

For the past year Plug Power has collaborated with partners Army Construction Engineering Research Laboratory and Warner Robins Air Force Base to demonstrate technical viability and increase market pull of hydrogen fuel cell systems. To date, 45 percent of the project has been completed and barriers are actively being addressed, including: cost, system reliability and market volume.

Results

Approximately four of Plug Power’s employees are supporting this effort to deploy 20 GenSys LPG-run units. Commercial suppliers are delivering stack, reformer and balance-of-plant components. In addition, Plug Power licensed this technology to IdaTech and Plug Power has proposed the use of IdaTech as a subcontractor for this project. Plans have been developed with IdaTech to provide resources for service, data analysis, and reliability assessment.

As of March 2011 Plug Power developed a detailed site plan for Robins Air Force Base in Warner Robins,

Georgia. The Warner Robins Air Logistic Center is the proposed building site and the units will be backing up key lighting circuits in the building. The site plan includes power interconnect strategy, operational layout, and site construction plans. A contractor was identified in the second quarter of 2011 and was hired to install infrastructure for the 10 systems. Work has progressed quickly and the site will be ready for systems in July 2011. In parallel, Plug Power has been performing pre-commissioning tests on 10 systems to ensure acceptable quality and performance standards are met. Eight of the systems have completed pre-commissioning tests and the remaining two should be ready in time for installation in July.

FIGURE 1. Progress at Robbins Air Force Base: (Left) Final Cement Poured for Systems Pad, (Right) Conduit and Interconnection Wiring

FIGURE 2. Backup Power for Engineering Building and Telecom Center will be Proposed: (Left) Engineering Building, (Right) Telecommunication Room.

**XIII. SMALL BUSINESS INNOVATION RESEARCH
(SBIR) HYDROGEN PROGRAM NEW PROJECTS
AWARDED IN FY 2011**

XIII.0 Small Business Innovation Research (SBIR) Hydrogen Program New Projects Awarded in FY 2011

The Small Business Innovation Research (SBIR) program provides small businesses with opportunities to participate in DOE research activities by exploring new and innovative approaches to achieve research and development (R&D) objectives. The funds set aside for SBIR projects are used to support an annual competition for Phase I awards of up to \$100,000 each for about nine months to explore the feasibility of innovative concepts. Phase II is the principal research or R&D effort, and these awards are up to \$750,000 over a two-year period. Small Business Technology Transfer (STTR) projects include substantial (at least 30%) cooperative research collaboration between the small business and a non-profit research institution.

Table 1 lists the SBIR projects awarded in FY 2011 related to the Hydrogen and Fuel Cells Program. On this and the following page are brief descriptions of each.

TABLE 1. FY 2011 SBIR Projects Related to the Hydrogen and Fuel Cells Program

	Title	Company	City, State
XIII.1	Ultra-Lightweight High Pressure Hydrogen Fuel Tanks Reinforced with Carbon Nanotubes (Phase I Project)	Applied Nanotech, Inc.	Austin, TX
XIII.2	Alternative Fiber Evaluation and Optimization of Filament Winding Processing (Phase I Project)	Quantum Fuel Systems Technologies Worldwide, Inc.	Irvine, CA
XIII.3	New High Performance Water Vapor Membranes to Improve Fuel Cell Balance of Plant Efficiency and Lower Costs (Phase I Project)	Tetramer Technologies, LLC	Pendleton, SC
XIII.4	Fuel Cell Range Extender for Battery-Powered Airport Ground Support Equipment (Phase I Project)	Innovatek, Inc.	Richland, WA

PHASE I PROJECTS

XIII.1 Ultra-Lightweight High Pressure Hydrogen Fuel Tanks Reinforced with Carbon Nanotubes

Applied Nanotech, Inc.
3006 Longhorn Blvd.
Austin, TX 78758

One effective way to lower the weight, thus decreasing the carbon fiber usage and lowering the cost, of a carbon fiber reinforced plastic (CFRP) tank is to improve the mechanical properties of the CFRP composite resin matrix using nano-reinforcement. This project will reduce the cost of the carbon fiber by 30-40% by reducing the weight of the CFRP composite by 30-40% reinforced with carbon nanotubes used in the structure of the high-pressure hydrogen fuel tank, while maintaining or improving the performance of the tank at the regular weight while the fuel efficiency is significantly improved.

XIII.2 Alternative Fiber Evaluation and Optimization of Filament Winding Processing

Quantum Fuel Systems Technologies Worldwide, Inc.
17872 Cartwright Road
Irvine, CA 92614-6217

In an effort to improve emissions, reduce the carbon footprint and decrease the dependency on oil, this project will investigate alternative methods to lower the cost of hydrogen storage vessels.

XIII.3 New High Performance Water Vapor Membranes to Improve Fuel Cell Balance of Plant Efficiency and Lower Costs

Tetramer Technologies, LLC
657 South Mechanic Street
Pendleton, SC 29670-1808

This project will reduce the U.S. dependence on foreign oil and reduce hydrocarbon emissions, by lowering the cost of fuel cell technology for both stationary and transportation applications.

XIII.4 Fuel Cell Range Extender for Battery-Powered Airport Ground Support Equipment

Innovatek, Inc.
3100 George Washington Way, Suite 108
Richland, WA 99354-1663

InnovaTek will develop a fuel cell power system that operates on bio-jet fuel to facilitate the replacement of fossil fuels with renewable fuels for airport ground service equipment thereby improving environmental conditions at airports and their locals as well as improving energy security and sustainability for airport operations.

XIV. Acronyms, Abbreviations and Definitions

α -AlH ₃	Alpha polymorph of aluminum hydride	AC	Activated carbon
~	Approximately	AC	Alternating current
@	At	ACF	Activated carbon fibers
°C	Degrees Celsius	A/cm ²	Amps per square centimeter
°F	Degrees Fahrenheit	ACN	Acetonitrile
Δ	Change, delta	ACNT	Aligned carbon nanotube
ΔG	Gibbs free energy of reaction	AD	Anaerobic digestion
ΔH	Enthalpy of reaction, Enthalpy of hydrogenation	ADG	Anaerobic digester gas
ΔH°_f	standard heat of formation	ADM	Air delivery module
ΔK	Stress intensity factor	ADOPT	Automotive Deployment Option Projection Tool
ΔP	Pressure drop, pressure change	A&E	Architecture and engineering
≈	Equals approximately	AEO	Annual Energy Outlook
>	Greater than	AER	Absorption-enhanced reforming, all-electric range
≥	Greater than or equal to	AFM	Atomic force microscopy; anti-ferromagnetic
<	Less than	AFP	Automated fiber placement
≤	Less than or equal to	AFV	Alternative fuel vehicle
μ CHX	Microscale combustor/heat exchanger	Ag	Silver
μ c-Si	Microcrystalline silicon	AGC	Activated graphitic carbon
μ m	Micrometer(s), micron(s)	AgCl	Silver chloride
η	Viscosity	AGM	Absorbed glass mat
#	Number	A-h	Amp-hour
Ω	Ohm(s)	AHJ	Authorities having jurisdiction
Ω/cm^2	Ohm(s) per square centimeter	AIBN	Azobisisobutyl nitrile
$\Omega\text{-cm}^2$	Ohm-square centimeter	AISI	American Iron & Steel Institute
%	Percent	Al	Aluminum
®	Registered trademark	Al*	Aluminum particles catalyzed with titanium
\$	United States dollars	Al ₂ O ₃	Aluminum oxide
¹¹ B-NMR	Boron 11 Nuclear Magnetic Resonance	Al-AB	Aluminum-ammonia-borane
¹⁹ FNMR	¹⁹ Fluorine nuclear magnetic resonance	AlCl ₃	Aluminum chloride
1-D, 1D	One-dimensional	ALD	Atomic layer deposition
1Q	First quarter of the fiscal year	AlH ₃	Aluminum hydride; alane
2-D, 2D	Two-dimensional	ALS	Advanced Light Source at Lawrence Berkeley National Laboratory
2Q	Second quarter of the fiscal year	ALT	Accelerated life test
3-D, 3D	Three-dimensional	AM 1.5	Air Mass 1.5 solar illumination
3Q	Third quarter of the fiscal year	AMBH	Ammine metal borohydride
4Q	Fourth quarter of the fiscal year	AMFC	Anion exchange membrane fuel cell
6FPAEB-BPS100	Hexafluoro bisphenol A benzonitrile-biphenyl sulfone	AMR	Annual Merit Review
A	Ampere, amps	AMRL	Active magnetic regenerative liquefier
Å	Angstrom	AMRR	Active magnetic regenerative refrigerator
AAO	Anodic aluminum oxide	ANL	Argonne National Laboratory
AB	Ammonia-borane, NH ₃ BH ₃	APC	Adaptive process control

XIV. Acronyms, Abbreviations and Definitions

APR	Aqueous-phase reforming	BCM	Battery-charging mode
APU	Auxiliary power unit	BCN	Boron carbon nitride
Ar	Argon	Be	Beryllium
ARB	Air Resources Board	BE	Basic event
ARET	Alternative and renewable energy technologies	BET	Brunauer-Emmett-Teller surface area analysis method
ARRA	American Recovery and Reinvestment Act	BEV	Battery electric vehicle
As	Arsenic	BFZ1	BaFe _{0.90} Zr _{0.10} O ₃
ASAXS	Anomalous small-angle X-ray scattering	B-G	Boron doped graphitic material
a-Si	Amorphous silicon	B-H	Boron/hydrogen bond
a-SiC	Amorphous silicon carbide	B-H, BH	Borohydride
a-SiGe	Amorphous silicon germanium	BH ₄	Borohydride
a-SiN	Amorphous silicon nitride	Bi	Bismuth
ASME	American Society of Mechanical Engineers	BM	Ball-milled, ball mill
ASPEN	Modeling software, computer code for process analysis	bmimCl	1-butyl-3-methyl-imidazolium chloride
ASR	Area-specific resistance	BN	Boron-nitrogen
AST	Accelerated stress test	BNH	Boron-nitrogen-hydrogen
ASTM	ASTM International, originally known as the American Society for Testing and Materials	BNHx	Dehydrogenated ammonia-borane
AT	Ammonia triborane	BNL	Brookhaven National Laboratory
at%	Atomic percent	BOL	Beginning of life
ATG	Adenine,Thymine,Guanine, the 3 base combinations that indicate the first translatable amino acid on the DNA molecule	BOM	Bill of materials
atm	Atmosphere	BOP, BoP	Balance of plant
A-T-P	Aerosol through plasma	BOT	Beginning of test
ATP	Adenosine triphosphate; Advanced Technology Program	BPDC	Biphenyl-4,4'-dicarboxylate
ATPase	Adenosine triphosphatase	BPS	Bi Phenyl Sulfone
ATR	Autothermal reformer; autothermal reforming, attenuated total reflection	BPSH	Block polysulfone ether polymers
ATR-FTIR	Attenuated total reflectance Fourier transform infrared	BPV	Boiler and Pressure Vessel
ATRP	Atom transfer radical polymerization	Br	Bromine
a.u.	Arbitrary units	Br ₂	Diatomic bromine
Au	Gold	BSC	Bi-electrode supported cell
Avg	Average	BTE	4,4',4''-(benzene-1,3,5-triyltris(ethyne-2,1-diyl))tribenzoate
AZO	Aluminum zinc oxide	BTCD	Octa-carboxylate ligand
¹¹ B-NMR	Boron 11 Nuclear Magnetic Resonance	BTU, Btu	British thermal unit(s)
B	Boron	C	Carbon
B ₂ O ₃	Boron oxide; diboron trioxide	C	Coulomb
Ba	Barium	C ₂ H ₄	Ethylene
barg	Bar gauge	C ₂ H ₆	Ethane
BBC	4,4',4''-(benzene-1,3,5-triyl-tris(benzene-4,1-diyl))tribenzoate	C ₃ H ₈	Propane
BCC	Body-centered cubic	Ca	Calcium
		CA	Carbon aerogel
		CAD	Computer-aided design
		CAE	Computer-assisted engineering
		CAES	Compressed air energy storage
		CaFCP	California Fuel Cell Partnership
		CAFE	Corporate Average Fuel Economy

CaI	<i>Clostridium acetobutylicum</i> hydrogenase	CGO	Cerium gadolinium oxide, Gd-doped CeO ₂
CaO	Calcium oxide	CGS	Copper gallium diselenide, CuGaSe ₂
CARB	California Air Resources Board	CGSe	Copper gallium diselenide
CaS	Calcium sulfide	CGSe ₂	Copper gallium diselenide
CB	Conduction band	CH	Hydrogenated graphene
CBM	Conduction band minimum	cH ₂	Compressed hydrogen gas
CBN	Carbon-boron-nitrogen	CH ₄	Methane
CBS	Casa Bonita strain, complete basis set	CHARM	Cost-effective High-efficiency Advanced Reforming Module
cc	Cubic centimeter(s)	CHHP	Combined heat, hydrogen, and power
CC	Crossover current	Chl	Chlorophyll
CCC	Carbon composite catalyst	CHMC	Compressed Hydrogen Materials Compatibility
CCD	Charge-coupled device	CHP	Combined heat and power
CCD	Catalytic cracking deposition	CHPFC	Combined heat and power fuel cell
cc/g cat/hr	Cubic centimeter(s) per gram catalyst per hour	CHS	Chemical hydrogen storage
CcH2	Cryo-compressed hydrogen	CHSCoE	Chemical Hydrogen Storage Center of Excellence
CCM	Catalyst-coated membrane; coordinate measuring machine	CIGSe	Copper indium gallium diselenide
Cc/min, ccm	Cubic centimeters per minute	CIGSe ₂	Copper indium gallium diselenide
ccp	Cubic close-packing	CIS	CuInSe (alloy of copper, indium, and selenium)
CCP	Combined cooling and power	Cl	Chlorine
CCS	Carbon capture and storage	CL	Catalyst layer
CCVJ	9-([E]-2-carboxy-2-cyanovinyl)julolidine	cm	Centimeter
Cd	Cadmium	CM	Controls module
CD	Compact disk, charge depleting, cathode dewpoint	cm ²	Square centimeter
CDC	Carbide-derived carbon	CMM	Coordinate measuring machine
cDNA	Complementary DNA	CMO	Conductive metal oxides
CDO	Code development organization	CMR	Composite membrane reactor
CDP	Composite data product	CMWNT	Carbon multi-walled nanotube
CdS	Cadmium sulfide	CN	Carbon-nitrogen
Ce	Cerium	CNF	Carbon nano-fiber
CE	Cluster Expansion	CNG	Compressed natural gas
CEA	Commissariat à l'Énergie Atomique	CNO	Cesium niobate
CEC	California Energy Commission	CNP	Combinatorial nanoparticle
CEM	Compressor/expander motor	CNT	Carbon nanotube
CEMG	Compressor expander motor-generator module	Co	Cobalt
CEMM	Compressor-expander motor module	CO	Carbon monoxide
CeO ₂	Ceric oxide	CO ₂	Carbon dioxide
CEPCI	Chemical Engineering's Plant Cost Index	CoE	Center of Excellence
CF	Carbon fiber, carbon foam	COE	Cost of electricity
CFD	Computational fluid dynamics	COF	Covalent-organic framework
cfm	Cubic feet per minute	COF ₂	Carbonyl fluoride
CFP	Carbon fiber paper	COPV	Composite overwrapped pressure vessel
CFRP	Carbon fiber reinforced plastic	COS	Carbon oxysulfide; carbonyl sulfide
CGH2	Compressed gaseous hydrogen	c _p	Specific heat

XIV. Acronyms, Abbreviations and Definitions

CpI	<i>Clostridium pasteurianum</i> [FeFe]- hydrogenase	DEDP	Distance Education Degree Program
CPO, CPOX	Catalytic partial oxidation	Deg	Degree
CPV	Composite pressure vessel	DEGDBE	Diethylene glycol dibutyl ether
Cr	Chromium	ΔB_a	The difference in magnetic induction at high and low applied magnetic fields
CR	Compression ratio	ΔG	Gibbs free energy of reaction
CRADA	Cooperative Research and Development Agreement	ΔH	Enthalpy of reaction, Enthalpy of hydrogenation
Cs	Cesium	ΔH_f°	standard heat of formation
CS	Ceramic support	ΔK	Stress intensity factor
C&S	Codes and standards	ΔP	Pressure drop, pressure change
CSA	Canadian Standards Association	DFC	Direct fuel cell
CSA	Cell stack assembly	DFM	Design for manufacturing
CSTT	Codes and Standards Tech Team	DFMA [®]	Design for Manufacturing and Assembly
CSU	California State University	DFT	Density functional theory
CTAB	Cetyl trimethyl ammonium bromide	DI	Deionized, de-ionized water
CTE	Coefficient of thermal expansion	DLA	Defense Logistics Agency
CTTRANSIT	Connecticut Transit	DLC	Diamondlike carbon
Cu	Copper	dL/g	Deciliters per gram
CU	University of Colorado	DLS	Dynamic light scattering
Cu ₂ O	Cuprous oxide	DM	Diffusion media
cu in.	Cubic inch	DMC	Diffusion Monte Carlo, direct manufactured cost
CuO	Cupric oxide, copper(II) oxide	DME	Dimethyl ether, dimethoxyethane
cu.yd.	Cubic yard(s)	DMEA	Dimethylethylamine
CV	Cyclic voltammetry; cyclic voltammogram	DMEAA	Dimethylethylamine alane
CVD	Chemical vapor deposition	DMF	n, n-di-methyl formamide
CVM	Cell voltage monitor	DMFC	Direct methanol fuel cell
CWRU	Case Western Reserve University	DNA	Deoxyribonucleic acid
CY	Calendar year	DNG	Desulfurized natural gas
CZO	Ceria-zirconia	DOD	Depth of discharge
d	Day(s)	DOD	U.S. Department of Defense
D ₂	Deuterium	DOE	U.S. Department of Energy
D-A	Dubinini-Astakhov	DOT	Department of Transportation
DB	Diborane (B ₂ H ₆)	DOT/NHTSA	Department of Transportation/National Highway Traffic Safety Administration
dB(A)	Decibel(s) A scale	DP	Dew point
DBBPDSA	4, 4'-dibromobiphenyl 3, 3'-disulfonic acid, monomer	DP4	Design Prototype 4
DBPDSA	1, 4-dibromo phenylene 2, 5-disulfonic acid	DRIFTS	Diffuse reflectance infrared Fourier transform spectroscopy
DC	Direct current	DSC	Differential scanning calorimetry; dynamic scanning calorimetry
DCHX	Direct contact heat exchanger	DSM [™]	Dimensionally stable membrane
DCTDD	1,8-diazacyclotetradecane-2,7-dione	DTA	Differential thermal analysis
DDGS	Distiller's dried grains	DVD	Digital video disk
DDMEFC	Direct dimethyl ether fuel cell	e ⁻	Electron
DDP	Detailed Data Products	E	Activation energy, kJ/mol
d_{DR}	Dubini-Radushkevich average micropore diameter	E85	85%-15% blend of ethanol with gasoline
DDR	A zeolite structure code		

Ea	Activation energy	ES	Energy storage
E_{ad}	Hydrogen adsorption heat	ESA	Electrochemically active surface area
EC	Electrochemical capacitance	et al.	<i>Et Alii</i> : and others
ECA	Electro-catalytic additive	etc.	<i>Et cetera</i> : and so on
ECA	Electrochemical area	E-TEK	Division of De Nora North America, Inc.
ECA	Estimated surface area	ETFE	Ethylene-tetrafluoroethylene
ECSA	Electrochemically active surface area, Electrochemical surface area	ETFECS	Extended thin film electrocatalyst structures
ECST	College of Engineering, Computer Science and Technology	EtOH	Ethanol
EDA	Ethylene diamine	eV	Electron volt
EDAX	Manufacturer of energy dispersive X-ray hardware and software	EVOH	Ethylene vinyl alcohol
EDS	Energy dispersive X-ray spectroscopy, energy dispersive spectrum	EW	Enthalpy wheel
EDTA	Ethylenediamine tetraacetic acid	EW	Equivalent weight
EDX	Energy dispersive X-ray	EWH	Enthalpy wheel humidifier
EECBG	Energy Efficiency and Conservation Block Grant	EXAFS	Extended X-ray absorption fine structure analysis
EELS	Electron energy loss spectroscopy	F	Fluorine
EER	Miles per unit energy of hydrogen used in a FCV/miles per unit energy of gasoline used in an ICEV	F	Faraday constant, the amount of electric charge in one mole of electrons (96,485.3383 coulomb/mole)
EERE	U.S. DOE Office of Energy Efficiency and Renewable Energy	F ⁻	Fluorine ion
EFC	Energy flow chart	FA	Furfyl alcohol
EFP	External fuel processor	FAT	Fleet Analysis Toolkit; factory acceptance test
EFTE	Ethylene-tetrafluoroethylene	FC	Fuel cell
EHC	Electrochemical hydrogen compressor	FCB	Fuel cell bus
EHS	Environmental Health and Safety	FCC	Face-centered cubic; Fuel Cell Catalyst
EIA	Energy Information Administration of the U.S. Department of Energy	FCE	FuelCell Energy
EIS	Electrochemical impedance spectroscopy	F-Cell	Daimler Fuel Cell vehicle
EISA	Evaporation induced self assembly	FCEV	Fuel cell electric vehicle
e.g.	<i>Exempli gratia</i> : for example	FCFP	FreedomCAR and Fuel Partnership
ELAT [®]	Registered Trademark of De Nora North America, Inc., covers GDLs and GDEs	FCHEA	Fuel Cell Hydrogen Energy Association
EMF	Electromagnetic field	FCPP	Fuel cell power plant
EMPA	Electron microprobe	FCS	Fuel cell system
EMTEC	Edison Materials Technology Center	FCT	Fuel Cell Technologies
ENG	Expanded natural graphite	FC ^{TESQA}	Fuel Cell Testing, Safety and Quality Assurance (an international effort to harmonize fuel cell testing procedures)
eNMR	Electrochemical nuclear magnetic resonance	FCTESTNET	Fuel Cell Testing and Standardization Network
EOL	End of life	FCTT	Fuel Cell Technical Team
EOT	End of test	FCV	Fuel cell vehicle
EPA	U.S. Environmental Protection Agency	Fd	Ferredoxin
EPRI	Electric Power Research Institute	Fe	Iron
ePTFE	Expanded polytetrafluoroethylene	Fe ₂ O ₃	Ferric oxide
ERW	Electric resistance weld	FEA	Finite element analysis
		FEM	Finite element model
		FEP	Fluorinated ethylene propylene; Teflon [®]
		FESEM	Field emission scanning electron microscope

XIV. Acronyms, Abbreviations and Definitions

FF	Flammability factor	GC-MS	Gas chromatograph-mass spectroscopy
FFT	Fast fourier transform	GCNT	Graphitized carbon nanotubes
FHI	Florida Hydrogen Initiative	GCTool	Software package developed at ANL for analysis of fuel cells and other power systems
FHWA	Federal Highway Administration	Gd	Gadolinium
FIB	Focused ion beam	GDC	Gadolinium-doped ceria
FIT	Florida Institute of Technology	GDE	Gas diffusion electrode
FLUENT	Computer code for computational fluid dynamics	GDL	Gas diffusion layer
FMEA	Failure modes and effects analysis	GDM	Gas diffusion media
FOM	Federated object model	Ge	Germanium
FOM	Figure of merit	Gen I	First generation
fpi	Fins per inch	GES	Giner Electrochemical Systems, LLC
fpm	Feet per minute	GF	Glass fiber
FPS	Bis(4-fluorophenyl)sulfone, Fuel processing system	GFC	Gas flow channel
FRP	Fiber-reinforced composite piping; fiber-reinforced polymer	GGA	Generalized gradient approximation
FRR	Fluoride release rate	GGE, gge	Gasoline gallon equivalent
FSEC	Florida Solar Energy Center	GH ₂	Gaseous hydrogen
F-SPEEK	Fluorosulfonic acid of polyetheretherketone	GHG	Greenhouse gas
FSW	Friction stir welding	GHSV	Gas hourly space velocity
ft	Feet	GIS	Geographic information system
FT	Fault tree	GJ	Gigajoule(s)
ft ²	Square feet	g/kW	Gram(s) per kilowatt
ft ³	Cubic feet	GLACD	Glancing angle co-deposition
FTA	Federal Transit Administration	GLAD	Glancing angle deposition
FT-IR, FTIR	Fourier transform infrared	GLY	Glycerol
FTIR-ATR	Fourier transform infrared attenuated total reflection	Glyme	Dimethoxyethane
FTO	Fluorine-doped tin oxide	gm	Gram(s)
FTP, FTP-75	Federal Test Procedure	GM	General Motors
FW	Formula weight	gm/day	Gram(s) per day
FW	Filament winding	g/min	Gram(s) per minute
FY	Fiscal year	GNF	Graphite nanofiber
g	Gram; acceleration of gravity	GPa	Gigapascal(s)
G	Graphite	GREET	Greenhouse gases, Regulated Emissions and Energy use in Transportation model
Ga	Gallium	g/s	Grams per second
GaAs	Gallium arsenic	GSE	Ground support equipment
gal	Gallon	GTI	Gas Technology Institute
GaP	Gallium phosphide	GTR	Global Technical Regulations
GB	Gigabyte	GUI	Graphical user interface
GC	Gas chromatograph; general computational	GWe	Gigawatt(s) electric
GC	Glassy, or vitreous carbon; a pure carbon that is amorphous (non- crystalline)	h	Hour(s)
g/cc	Grams per cubic centimeter	H	Hydrogen
GCLP	Grand-canonical linear programming	H+	Proton
GCMC	Grand Canonical Monte Carlo	H ⁻	Hydride
		H ₂	Diatomic hydrogen
		H2A	Hydrogen Analysis project sponsored by DOE

H ₂ -ICE, H ₂ ICE	Hydrogen internal combustion engine	HHV	Higher heating value
H ₂ O	Water	HI	Hydrogen iodide, hydriodic acid
H ₂ O ₂	Hydrogen peroxide	HIA	Hydrogen-induced amorphization, Hydrogen Implementing Agreement
H2QWG	DOE Hydrogen Quality Working Group	HICE	Hydrogen internal combustion engine
H ₂ S	Hydrogen sulfide	HIx	Blend of hydrogen iodide, iodine, and water
H ₂ SO ₄	Sulfuric acid	HLA	High level architecture
H ₃ PO ₄	Phosphoric acid	HMC	Hyundai Motor Company
HAADF	High-angle annular dark-field	HMM	Hydrogen Market Model
HAADF-STEM	High angle annular dark field scanning transmission electron microscopy	HNEI	Hawaii Natural Energy Institute
HAMMER	Hazardous Materials Management and Emergency Response	HNO ₃	Nitric acid
HAVO	Hawaii Volcanoes National Park	HOPG	Highly-ordered pyrolytic graphite
HAZ	Heat affected zone	HOR	Hydrogen oxidation reaction
HAZID	Hazard Identification Analysis	hp	Horsepower
HAZOP	Hazards and Operational Safety Analysis, hazards and operability analysis	HP	High-pressure
HBP	Hyperbranched polymer	HPA	Heteropoly acid
HBr	Hydrogen bromide	HPIT	Hydrogen Powered Industrial Truck
HCC	Hybrid cathode catalyst	HPLC	High performance liquid chromatography
HCl, HCL	Hydrochloric acid, Hydrogen chloride	HPPH	1,6-di(4-hydroxyl)phenylperfluorohexane
HClO ₄	Perchloric acid	HPPS	<i>N,N</i> -diisopropylethylammonium 2,2-bis(<i>p</i> -hydroxyphenyl) pentafluoropropanesulfonate
H ₂ CO	Hydrogen coordination number	HPR	Hydrogen production rate
hcp	Hexagonal close-packing	HPRD	Hydrogen pressure relief device
HDPE	High-density polyethylene	hr	Hour(s)
HDSAM	Hydrogen Delivery Scenario Analysis Model	HRA	Home refueling appliance
He	Helium	HRT	Hydraulic retention times
HE	Hydrogen embrittlement	HRTEM	High-resolution transmission electron microscopy
H-E-B	H-E-B Grocery Company, Inc.	HSC	Database name derived from the letters for enthalpy, entropy and heat capacity
HEPA	High efficiency particulate air filter	HSCoE	Hydrogen Sorption Center of Excellence
HER	Hydrogen evolution reaction	HSDC	Hydrogen Secure Data Center
HEV	Hybrid electric vehicle	HSE	High surface area electrode
HEX	Heat exchanger	HSECoE	Hydrogen Storage Engineering Center of Excellence
Hf	Hafnium	HSM	Hydrogen storage module
HF	Hydrogen Fueler	HSMCoE	Hydrogen Storage Material Center of Excellence
HF	Hydrofluorhydric acid, hydrogen fluoride, Hartree Fock	HSO ₄	Bisulfate anion
HFB	Hexafluorobenzene	HSP	Hydrogen safety plan
HFC	Hydrogen fuel cell	HSS	Hierarchically structured silica
HFCIT	Hydrogen, Fuel Cells and Infrastructure Technologies Program	HSSIM	Hydrogen Storage SIMulator
HFCT	Hydrogen and fuel cell technology	HSU	Humboldt State University
HFCV	Hydrogen fuel cell vehicle	HTAC	Hydrogen and Fuel Cell Technical Advisory Committee
HFI	Hydrogen Fuel Initiative	HTC	High temperature coolant
HFP	Hexafluoropropylene	HTE	High-temperature electrolysis
HFR	High-frequency resistance		
HFV	Hydrogen-fueled vehicle		

XIV. Acronyms, Abbreviations and Definitions

HTF	Heat transfer fluid, Hydrogen test fixture	IGCC-CMR	Integrated gasification combined cycle-catalytic membrane reactor
HTFSA	Trifluomethylsulfonic acid	IGCC-MR	Integrated gasification combined cycle-membrane reactor
HTM	High-temperature membrane	IGCC-PBR	Integrated gasification combined cycle-paladium-based reactor
HTM	Hydrogen transport membrane	IGT	Institute of Gas Technology
HTMWG	High Temperature Membrane Working Group	IHPV	Internally heated high-pressure vessel
HTWGS	High-temperature water-gas shift	IL	Illinois
HVAC	Heating, ventilation and cooling	IL	Ionic liquid
HWD	Hot wire deposition	ILS	Integrated laboratory scale, Instrument landing systems
HWFET	Highway Fuel Economy Test	IML	Inner mold line
HX	Heat exchanger	In	Indium
HyDRA	Hydrogen Demand and Resource Analysis	In., in	Inch
HYPHER	HYdrogen PERmitting	in ²	Square inch
HyPro, HYPRO	Analysis tool	INER	Institute of Nuclear Energy Research
HyS	Hybrid sulfur	InP	Indium phosphorus
HYSYS®	Process simulation software by AspenTech, computer code for flowsheet analysis	INS	Inelastic neutron scattering
HyTEC	Hydrogen Technology and Energy Curriculum	IOS	Intelligent Optical Systems, Inc.
HyTEch	Hydrogen Technical Experimental (database)	IP	Induction period
HyTRANS	DOE's market simulation model for the transition to hydrogen vehicles	IP	Intellectual property
Hz	Hertz	IPA	Isophthalate
HZM	Hot zone module	IPA	Isopropyl alcohol
i	Current density (mA/cm ²)	IPCC	Intergovernmental Panel on Climate Change
I	Current	IPES	Inverse photoemission spectroscopy
I ₂	Diatomic iodine	IPHE	International Partnership for the Hydrogen Economy
IC	Internal combustion	IR	Infrared
ICC	International Code Council	iR	Internal resistance; voltage loss due to resistance
ICE	Internal combustion engine	Ir	Iridium
ICEV	Internal combustion engine vehicle	IR/DC	Infrared diagnostic system with direct current excitation
ICP	Inductively coupled plasma	IRMOF	Isorecticular metal organic framework
ICPME	Institut de Chimie et des Matériaux	IrO _x	Iridium oxide
ICP-MS	Inductively coupled plasma mass spectrometry	ISO	International Organization for Standardization
ICR	Interfacial contact resistance	ISS	Ion scattering spectroscopy
ID	Inside diameter	ITM	Ion transport membrane
i.e.	<i>id est</i> : that is	ITO	Indium tin oxide
IEA	International Energy Agency	ITP	Indium tin phosphate
IEA-HIA	International Energy Agency Hydrogen Implementing Agreement	IV	Current-voltage
IEC	Ion exchange capacity; milliequivalents of acid groups per gram of material	J	Current
IFC	International Fire Code	J	Hydrogen flux through the membrane, ml/[cm ² -min]
IFE	In-flight entertainment	J	Joule(s)
IGCC	Integrated gasification combined cycle	JFK	John F. Kennedy (airport)

JM	Johnson Matthey	LANL	Los Alamos National Laboratory
JMFC	Johnson-Matthey Fuel Cells, Inc.	LAO	Lanthanum-modified alumina
JPL	Jet Propulsion Laboratory	LAX	Los Angeles International Airport
JRC	Joint Research Centre	lb	Pound(s)
J-V	Current density-voltage	LBM	Lattice Boltzmann method
K	Sievert's constant, ml/[cm ² -min-atm ^{1/2}]	lbmol	Pound-mole(s)
K	Kelvin, absolute temperature	LBL	Lawrence Berkeley National Laboratory
K	Potassium	LC	Liquid carrier
kÅ	1000 angstroms	LCA	Life cycle assessment; life-cycle analysis
kA/m ²	Kilo-ampere(s) per square meter	LCC	Life cycle cost
kb	Kilo-base pair, a unit of measurement used in genetics equal to 1,000 nucleotides	LCC	La _{0.7} Ca _{0.3} CrO _{3-δ}
KBr	Potassium bromide	LCH ₂	Hydrogenated liquid carrier; compressed hydrogen produced from liquid hydrogen
kcal	Kilocalorie(s)	LCH ₂	Liquid to compressed hydrogen
kcal/mol	Kilocalorie(s) per mole	LC-MS	Liquid chromatography-mass spectroscopy
KeV	Kilo electron volt(s)	L/D	Length to diameter ratio
kg	Kilogram(s)	LDPE	Low density poly-ethylene
kg/d	Kilogram(s) per day	LDV	Light-duty vehicle
kg/hr	Kilogram(s) per hour	LED	Light emitting diode
kg/m ³	Kilogram(s) per cubic meter	LEF	linear electron transfer
KH	Potassium hydride	LEL	Lower explosion limit
kHz	Kilohertz	LFG	Landfill gas
K _{IH}	Fracture toughness measured in hydrogen gas	LFL	Lower flammability limit
kJ	Kilojoule(s)	L/h, l/h	Liter(s) per hour
K _{JIC}	Fracture toughness	LH ₂ , LH ₂	Liquid hydrogen
kJ/mol	Kilojoule(s) per mole	LHC	Light-harvesting chlorophyll
km	Kilometer(s)	LHS	Lawrence Hall of Science
KMC	Kinetic Monte Carlo, Kilauea Military Camp, Kia Motors Corporation	LHSV	Liquid hourly space velocity, h ⁻¹
KOH	Potassium hydroxide	LHV	Lower heating value
kPa	Kilopascal(s)	Li	Lithium
kph	Kilometer(s) per hour	Li ₃ N	Lithium nitride
K _{th} , K _{th}	Fracture toughness threshold	Li-AB	Lithium amidoborane, Li-NH ₂ -BH ₃
K _{TH}	Hydrogen-assisted crack growth threshold	LiBH ₄	Lithium borohydride
kW	Kilowatt(s)	LIBS	Laser-induced breakdown spectroscopy
kW _e	Kilowatt(s) electric	LiH	Lithium hydride
kWh	Kilowatt-hour(s)	LIM	Liquid injection molding, liquid injection moldable
kWh/kg	Kilowatt-hour(s) per kilogram	LLC	Limited Liability Company
kWh/L	Kilowatt-hour(s) per liter	LLC	Lessons Learned Corner
kW/kg	Kilowatt(s) per kilogram	LLNL	Lawrence Livermore National Laboratory
kWt	Kilowatt(s) thermal	LMWO	Lanthanum molybdenum tungsten oxide (e.g., La ₂ Mo _{1.8} W _{0.2} O _{9-x})
L, l	Liter(s)	L/min, l/min	Liter(s) per minute
La	Lanthanum	LN ₂	Liquid nitrogen
LAGP	Lithium aluminum germanium phosphate	LNG	Liquefied natural gas
λ	Lambda, hydration number	LOD	Limit of detection
LAMH	Lithium amide and magnesium hydride	LP	Lattice parameter

XIV. Acronyms, Abbreviations and Definitions

LPG	Liquefied petroleum gas	MASC	Multi-acid side-chain
LPM	Liters per minute	MB	Megabyte
LPR	Liquid-phase reforming	MBE	Molecular beam epitaxy
LQ*	Dehydrogenated liquid carrier	MBL	Modified boundary layer
LQ*H2	Hydrogenated liquid carrier	MBMS	Molecular beam mass spectrometry
LRS	Laser raman spectroscopy	MBRC	Miles between roadcall
LSAC	Low surface area carbon	MC	Monte Carlo
LSC	Lanthanum strontium cobalt oxide, (La, Sr) CoO ₃ , strontium-doped lanthanum cobaltite, La _{0.8} Sr _{0.2} CoO _{3+δ}	MC	Microchannel
LSCF	Lanthanum strontium cobalt iron oxide, (La, Sr)(Co, Fe)O ₃	MC	Methyl cellulose
LSCM	Lanthanum strontium chromium manganese oxide, (La, Sr)(Cr, Mn)O ₃	mC ²	Multi-component composite (membrane)
LSCr	Lanthanum strontium chromium oxide, (La, Sr)CrO ₃	MCB	Marine Corps Base
LSL	Lower specification limit	mC-cm ⁻²	MilliCoulomb(s) per square centimeter
LSM	Lanthanum strontium manganese	MCFC	Molten carbonate fuel cell
LSMO	Lanthanum strontium manganese oxide, (La, Sr)MnO ₃ , strontium-doped lanthanum manganite, La _{0.8} Sr _{0.2} MnO _{3+δ}	mCHP	Micro-combined heat and power
LST	Lanthanum strontium titanium oxide, (La, Sr)TiO ₃	μc-Si	Microcrystalline silicon
LSV	Lanthanum strontium vanadate, Linear sweep voltammetry	MDE	Mid-duty electric
LT	Low-temperature	MDES	Methyl-diethoxy silane
LTC	Low temperature coolant	MEA	Membrane electrode assembly
m	Meter(s)	MeAB	Methylamine borane
M	Mole, molar	MEC	Microbial electrolysis cell, Minimum explosive concentration
M	Million	MeCN	Acetonitrile
m ²	Square meter(s)	MeOH	Methanol
m ² /g	Square meter(s) per gram	MEP	Minimum energy pathway
m ² /s	Square meter(s) per second	meq	Milliequivalents
m ³	Cubic meter(s)	meq/g	Milliequivalents/gram
MA	Mass activity; methyl acrylate	MeV	Mega electron volt
MAAT	Many-at-a-time	MFI	A zeolite structure code
μA	Micro ampere(s)	Mg	Megagram(s)
mA	MilliAmps (s)	μg	Microgram(s)
MA	Mass activity	mg	Milligram(s)
M-AB	Metal ammonia-borane	MG	Miscanthus giganteus
MAB, M-AB	Metal amidoboranes	MgCl ₂	Magnesium chloride
μA/cm ²	Micro ampere(s) per square centimeter	mg/cm ²	Milligram(s) per square centimeter
mA/cm ²	Milliamp(s) per square centimeter	MgH ₂	Magnesium hydride
MAS	Magic angle spinning	MgO	Magnesium oxide
MAS ¹¹ B-NMR	Magic angle spinning boron-11 nuclear magnetic resonance spectroscopy	Mg(OH) ₂	Magnesium hydroxide
MAS-NMR	Magic angle spinning nuclear magnetic resonance	MH, M-H	Metal hydride
		MHC	Metal hydride-based compressor
		MHCoE	Metal Hydride Center of Excellence
		MHE	Material handling equipment
		MHz	Megahertz
		mi	Mile(s)
		μCHP	Micro-combined heat and power
		μCHX	Microscale combustor/heat exchanger
		MIE	Minimum ignition energy
		MIEC	Mixed ionic and electronic conduction

mi/kg	Mile(s) per kilogram	MSR	Metal-steam reforming
mil	Millimeter(s)	MSR	Membrane steam reformer
min	Minute(s)	MTBF	Mean time between failure
MIT	Massachusetts Institute of Technology	MTBR	Mean time between repairs
MiTi®	Mohawk Innovative Technologies Inc.	mtorr	Millitorr
MJ	Megajoule(s)	μV	Micro volt(s)
mL, ml	Milliliter(s)	mV	Millivolt(s)
ML	Monolayer	MV	Methyl viologen
MLCT	Metal-to-ligand charge-transfer	mW	Milliwatt(s)
MLI	Multi-layer vacuum insulation	MW	Megawatt(s)
μm	Micrometer(s); micron(s)	MW	Molecular weight
μM	Micromolar	mW/cm ²	Milliwatt(s) per square centimeter
mM	Millimolar	MWCNT	Multiple-wall carbon nanotube
mm	Millimeter(s)	MWe	Megawatt(s) electric
MMBtu	Million British thermal units	MWh	Megawatt-hour(s)
MMOF	Microporous metal-organic framework	MWNT	Multi-wall carbon nanotube
mmol	Millimole(s)	MWOE	Midwest Optoelectronics, LLC
μmol	Micromole(s)	MWth	Megawatt(s) thermal
MMT	Million metric tonnes	MYPP	Multi-Year Program Plan (the HFCIT Program's Multi-Year Research, Development and Demonstration Plan), Multi-year product plan
Mn	Manganese	MYRDD, MYRD&DP	Multi-Year Research, Development and Demonstration Plan
Mn ₂ O ₃	Manganese oxide	N	Normal (e.g., 1N H ₃ PO ₄ is 1 normal solution of phosphoric acid)
M-N-H	Amide/imide	N	Nitrogen atom
MnO	Manganese oxide	N	Newton (unit of force)
mΩ	Milli-ohm(s)	N112	Nafion® 1100 equivalent weight, 2 millimeter thick membrane
MΩ	Mega-ohm(s)	N ₂	Diatomic nitrogen
mΩ/cm ²	Milli-ohm(s) per square centimeter	N ₂ O	Nitrous oxide
μΩ-cm ²	Micro-ohm(s) - square centimeter	Na	Sodium
Mo	Molybdenum	NA	North American
MOF	Metal-organic framework	Na ₂ S	Sodium sulfide
mol	Mole(s)	Na ₃ AlH ₆	Trisodium hexahydroaluminate
mol%	Mole percent	NaAlH ₄	Sodium aluminum hydride; sodium tetrahydroaluminate; sodium alanate
mol/min	Mole(s) per minute	NaBH ₄	Sodium borohydride
MOR	Methanol oxidation reaction	NaBO ₂	Sodium metaborate
MPa	Megapascal (s)	NaCl	Sodium chloride
MPG, mpg	Mile(s) per gallon	Nafion®	Registered Trademark of E.I. DuPont de Nemours
MPGGE	Miles per gasoline gallon equivalent	NaH	Sodium hydride
mph	Mile(s) per hour	NA NG	North American natural gas
MPL	Microporous layer	NaOH	Sodium hydroxide
mpy	Mils per year	NAS	National Academy of Sciences
MR	Membrane reactor		
MRI	Magnetic resonance imaging		
MRL	Manufacturing readiness level		
ms	Millisecond(s)		
MS	Mass spectroscopy, mass spectrometry		
MSAC	Mid-range carbon support		
mS/cm	Milli-Siemen(s) per centimeter		

XIV. Acronyms, Abbreviations and Definitions

NASA	National Aeronautics and Space Administration	NNA NG	Non-North American natural gas
NASCAR	National Association for Stock Car Auto Racing	NNIF	NIST neutron imaging facility
Nb	Niobium	NMOC	Non-methane organic carbons
N/cm ²	Newton(s) per square centimeter	NO ₂	Nitric oxide
NCCC	National Carbon Capture Center	NO _x , NO _x	Oxides of nitrogen
NCSL	National Conference of State Legislators	NP	Nanoparticle
ND	Not determined at this time	NPC	Nanoporous carbon; normalized photocurrent
NDA	Non-disclosure agreement	NPD	Neutron powder diffraction
NDC	New delivery concept, Naphthalene-2,6-dicarboxylate	NPGM	Non-precious metal group
NDE	Non-destructive examination	NPMC	Non-precious metal catalyst
NDP	Neutron depth profiling	NFPA	National Fire Protection Association
NDTE	Non-destructive testing and evaluation	NPM	Non-precious metal
NEB	Nudged elastic band	NPS	National Park Service
NEED	National Energy Education Development Project	NPT	Normal pressure and temperature
NE ISO	New England Independent System Operator	NPV	Net present value
NEMS	National Energy Modeling System	NR	Nanorod
NEPA	National Environmental Policy Act	NREL	National Renewable Energy Laboratory
NETL	National Energy Technology Laboratory	NRELFAT	NREL Fleet Analysis Toolkit
NFC	Near-frictionless coating	NSF	National Science Foundation
NFCRC	National Fuel Cell Research Center	NST	New stress test
NFM	Nanoporous framework material	NSTF	Nano-structured thin-film
NFPA	National Fire Protection Association	NT	Nanotube
ng	Nanogram	NTCNA	Nissan Technical Center, North America
NG	Natural gas	NVS	Neutron vibrational spectroscopy
NGV	Natural gas vehicle	NY ISO	New York Independent System Operator
NH ₃	Ammonia	Ω	Ohm(s)
NHE	Normal hydrogen electrode	Ωcm ²	Ohm(s) - square centimeter
NHI	Nuclear Hydrogen Initiative	O	Oxygen
Ni	Nickel	O ₂	Diatomic oxygen
NiMH	Nickel metal hydride	O/C	Oxygen-to-carbon ratio
NIR	Near infra-red	OCP	Open circuit potential
NIST	National Institute of Standards and Technology	OCV	Open-circuit voltage
NL	Normal liter(s)	o.d.,OD	Outer diameter
nm	Nanometer(s)	OEM	Original equipment manufacturer
NM	Noble metal	OER	Oxygen evolution reaction
Nm ³	Normal cubic meter(s)	OGMC	Ordered graphitic mesoporous carbon
NMHC	Non-methane hydrocarbons	OH	Hydroxyl radical
nmol	Nanomole(s)	O&M	Operation and maintenance
NMR	Nuclear magnetic resonance	OMC	Ordered mesoporous carbon
NMSU	New Mexico State University	OML	Outer mold line
NMT	New Mexico Tech	ORNL	Oak Ridge National Laboratory
NNA	Non-North American	ORNL-HTML	Oak Ridge National Laboratory High Temperature Materials Laboratory
		ORR	Oxygen reduction reaction
		OSC	Oxygen storage capability

OSM	Oregon Steel Mills, Optical scatterfield microscopy	PEM	Proton exchange membrane, Polymer electrolyte membrane
OSU	Ohio State University	PEMFC	Polymer electrolyte membrane fuel cell
OTM	Oxygen transport membrane	PEMFC	Proton exchange membrane fuel cell
P	Phosphorus	PEO	Poly(ethylene oxide)
P	Pressure	PES	Polyethersulfone
Pa	Pascal(s)	PET	Polyethylene terephthalate
PA	Phenylacetylene, Polyamide	PFA	Polyfurfuryl alcohol
PAA	Poly(acrylic acid)	PFD	Process flow diagram
PAD	Polymer assisted deposition	PFIA	Perfluoro imide acid
PAES	Poly(arylene-ether-sulfone)	PFPO	Perfluorinated propylene oxide
PAF	Porous aromatic framework	PFSA	Perfluorinated sulfonic acid, perfluorosulfonic acid, poly(fluorosulfonic acid)
PAFC	Phosphoric acid fuel cell		
PAN	Peroxyacetyl nitrate, polyacrylonitrile		
PANI	Polyaniline	PFSHQ	2-(5-fluorosulfonyl-3-oxaocetafluoropentyl)-1,4-dihydroxy-benzene
PAS	Photoactive semiconductor		
Pb	Lead	PGE	Platinum group element
PB	Polyborazylene	PG&E	Pacific Gas and Electric Company
PbA	Lead acid	PGM	Precious group metal, Platinum group metal
PBI	Polybenzimidazole	PGV	Puna Geothermal Ventures
PbO	Lead oxide	pH	Power of the hydronium ion
PC	Polycarbonate	<i>p</i> -H ₂	Para-hydrogen
PC	Personal computer	PHEV	Plug-in hybrid vehicle
PCA	Pyrenecarboxylic acid	PHS	Pumped hydro storage
PCE	Perchloroethylene	PI	Principal investigator
PCI	Pressure-composition isotherm	PI	Polyimide
PCL	Polycaprolactone	P&ID	Piping and instrumentation diagram, process and instrumentation diagram
PCM	Power control module		
PCR	Polymerase chain reaction	PIL, pIL	Protic ionic liquid
PCT, P-C-T	Pressure-concentration-temperature	PIM, pIM	Protic ionic membrane
PCTFE	Polychlorotrifluoroethylene	pK _a	Acid dissociation constant
Pd	Palladium	PLC	Programmable logic controller
PD	Pressure decay	PLRS	Planar laser Raleigh scatter
PdAg	Palladium-silver alloy	PM	Particulate matter
Pd-CR	Palladium-based chemical resistor	PNNL	Pacific Northwest National Laboratory
PdCu, Pd-Cu	Palladium-copper alloy	pO ₂	Oxygen partial pressure
PdCuTM	Palladium copper transition metal	POC	Proof of concept
PDF	Probability density function	POF	Polymeric-organic frameworks; Porous organic framework
PDMS	Polydimethylsiloxane		
PDU	Process development unit	POP	Porous organic polymers
PEEK	Polyether ether ether ketone	POSS	Polyhedral oligomeric silsesquioxane
PEFC	Polymer electrolyte fuel cell	POX	Partial oxidation
PEFC	Proton exchange fuel cell	PP	Polyphosphazene, polypropylene, poly(phenylene)
PEG	Polyethylene glycol		
PEGS	Prototype electrostatic ground state	PPA	polyphosphoric acid; polyphthalamide
PEI	Polyetherimide, polyethylene imine	ppb	Part(s) per billion
PEKK	Poly (ether ketone ketone)	ppbv	Part(s) per billion by volume

XIV. Acronyms, Abbreviations and Definitions

PPDSA	Poly (p-phenylene disulfonic acid)	PTW	Pump-to-wheels
PPI	Pore(s) per inch	PV	Photovoltaic; present value
ppm, PPM	Part(s) per million	PVA	Polyvinyl alcohol
ppmv	Part(s) per million by volume	PVC	Polyvinyl chloride
ppmw	Part(s) per million by weight	PVD	Physical vapor deposition
PPN	Porous polymer network	PVDC	Poly-vinylidene chloride
PPOR	Metalloporphyrin porous organic polymer	PVDF	Polyvinylidene fluoride
P-POSS	Phosphonic acid polyhedral oligomeric silsesquioxane	PVL	Print verification line
PPS	Polyphenylene sulfide	PVP	Polyvinylpyrrolidone
PPSA	Poly (p-phenylene sulfonic acid)	PVPP	Polyvinyl pyridinium phosphate
PPSA	Partial pressure swing adsorption	PVT, P-V-T	Pressure-Volume-Temperature
PPSU	Polyphenylsulfone	PXRD	Powder X-ray diffraction
PRD	Pressure relief device	Q	Neutron momentum transfer
PRO	Pressure retarded osmosis	Q1, Q2, Q3, Q4	Quarters of the fiscal year
PSA	Pressure swing adsorption, adsorber	QC	Quality control
PSAT	Powertrain Systems Analysis Toolkit, a vehicle simulation software package developed at Argonne National Laboratory	QCM	Quartz crystal microbalance
PSD	Particle size distribution, pore size distribution	QE	Quantum efficiency
PSEPVE	Perfluoro (4-methyl-3,6-dioxaoct-7-ene) sulfonyl fluoride	QENS	Quasielastic neutron scattering
PSf	Poly(arylene ether sulfone)	QFD	Quality function deployment
psi, PSI	Pound(s) per square inch	QLRA	Qualitative risk analysis
PSI	Photosystem I	QMC	Quantum Monte Carlo
psia	Pound(s) per square inch absolute	QNS	Quasielastic neutron scattering
psid	Pound(s) per square inch differential	QRA	Quantitative risk assessment
psig, PSIG	Pound(s) per square inch gauge	R	Universal or ideal gas constant, $8.314472 \text{ J} \cdot \text{K}^{-1} \cdot \text{mol}^{-1}$
PSII	Photosystem II	RAMAN	A spectroscopic technique
PSM	Protic salt membrane	R&D	Research and development
PSOFC	Planar solid oxide fuel cell	RD&D, R,D&D	Research, development & demonstration
PSS	Porous stainless steel, potentiostatic scan	RDE	Rotating disk electrode
PSU	Polysulfone	Re	Rhenium
PSU	Pennsylvania State University	Rf	Generic fluoroalkyl group
Pt	Platinum	RF, rf	Radio frequency
P-T	Pressure-temperature	RF	Roughness factor
Pt ₃ Co	Platinum-cobalt alloy	RFP	Request for proposals
Pt ₃ Fe	Platinum-iron alloy	RGA	Residual gas analyzer (analysis)
Pt ₃ Ni	Platinum-nickel alloy	Rh	Rhodium
PTA	Phosphotungstic acid	RH	Relative humidity
Pt/C	Platinum/carbon	RHE	Reference hydrogen electrode; reversible hydrogen electrode
PTFE	Teflon [®] – poly-tetrafluoroethylene	RNA	Ribo nucleic acid
Pt-FePO	Platinum iron phosphate	RNG	Renewable natural gas
PtO	Platinum oxide	RO	Reverse osmosis
PtO ₂	Platinum dioxide	ROM	Rough order of magnitude
PtRu	Platinum ruthenium	RPC	Ruthenium-polyridyl complex
		RPI	Rensselaer Polytechnic Institute

rpm	Revolution(s) per minute	SECA	Solid State Energy Conversion Alliance
RPS	Renewable portfolio standard	SEDS	State Energy Data System
RRC	Regional resource center	SEM	Scanning electron microscopy, scanning electron microscope
RRDE	Rotating ring disc electrode	SEM	Secondary electron microscopy
RRW	Risk reduction worth	SEPUP	Science Education for Public Understanding Program
RSA	Random sequential adsorption	SERA	Scenario Evaluation, Regionalization and Analysis
RSOFC	Reversible solid oxide fuel cell	SET	Surface Energy Treatment
RT	Room temperature	SF	Polystyrene-b-PFPO
RTD	Resistive thermal device	SF ₆	Sulfur hexafluoride
Ru	Ruthenium	SFA	Sulfonic acid
s	Second(s)	SFO	San Francisco International Airport
S	Siemen(s)	SGD	Spontaneous galvanic displacement, system gravimetric density
S	Sulfur	SHE	Standard hydrogen electrode
SA	Specific amperage	Si	Silicon
SA	Sulfur-ammonia thermochemical water-splitting cycle	S-I	Sulfur-iodine
SAC	Site acquisition	SI	Sulfur-iodine cycle; spectrum image
SAE	SAE International, originally known as the Society of Automotive Engineers	Si ³ N ⁴	Silicon nitride
SAFC	Solid acid fuel cell	SiC	Silicon carbide
SAH	Sodium aluminum hydride	SiCN	Silicon carbonitride
SAM	Scanning Auger microscopy	SIMS	Secondary ion emission spectroscopy
SANS	Small angle neutron scattering	SiO ₂	Silicon dioxide
SAXS	Small angle X-ray scattering	SIU	Southern Illinois University
S _{BET}	BET specific surface area	sL	Standard liter (0°C, 1 atm)
SBIR	Small Business Innovation Research	SLD	Simplified local density
SBTS	Stack Block Test System	slpm, slm, sL/min	Standard liter(s) per minute
SBU	Secondary building unit	SMR	Steam methane reformer; steam methane reforming
Sc	Scandium	Sn	Tin
S/C	Steam to carbon ratio	SNL	Sandia National Laboratories
sccm, SCCM	Standard cubic centimeter(s) per minute	SNR	Signal-to-noise ratio
SCE	Saturated calomel electrode	SNTT	Spiral notch torsion test
SCF, scf	Standard cubic feet, supercritical fluid	SLAC	Stanford Linear Accelerator Center
scfd	Standard cubic feet per day	SLPH	Standard liter(s) per hour
SCFH, scfh	Standard cubic feet per hour	SLPM	Standars liter(s) per minute
SCFM	Standard cubic feet per minute	SLT	Strontium-doped lanthanum titanate
S/cm	Siemen(s) per centimeter	SnO	Tin oxide
SCOF	Single cell with open flowfield	SnO ₂	Tin oxide
SC-PC	Supercritical pulverized coal	SO ₂	Sulfur dioxide
SCR	Selective catalytic reduction	SO ₃	Sulfur trioxide
SCS	Solution combustion synthesis	SOC	State-of-charge
SCT-MAT	Short Circuit MicroActivity Testing	SOEC	Solid oxide electrolysis cell; solid oxide electrolyzer cell
SD	Standard deviation, System dynamics	SOFC	Solid oxide fuel cell
SDO	Standards development organization		
Se	Selenium		
sec	Second(s)		
SEC	Size exclusion chromatography		

XIV. Acronyms, Abbreviations and Definitions

SO FEC	Solid oxide fuel-assisted electrolysis cell	t	Time
SO _x	Oxides of sulfur	T _{1bar}	Temperature at which equilibrium pressure of hydrogen is 1 bar for a hydrogen exchange reaction
sPAES	Sulfonated poly(arylene ether sulfone)	Ta	Tantalum
SPEEK	Sulfonated poly(ether ether ketone)	TAG	Technical Advisory Group
SPEK	Sulfonated poly-etherketone-ketone	TBAB	Tetra- <i>n</i> -butylammonium bromide
SPEKK	Sulfonated polyether(ether ketone ketone)	TBA ₂ B ₁₂ H ₁₂	Tetra- <i>n</i> -butylammonium dodecahydrododecaborate
SPEX	Type of milling machine	TBABh	Tetra- <i>n</i> -butylammonium borohydride
SPM	Scanning probe microscope	TBA-PF ₆	Tetra- <i>n</i> -butylammonium hexafluorophosphate
sPOSS	sulfonated octaphenyl polyhedral oligomeric silsesquioxanes	TBD	To be determined
sq. in.	Square inch(es)	TC	Thermocouple
Sr	Strontium	TC	Transparent conducting
SR	Steam reformer; steam reforming	TCCR	Transparent, conducting and corrosion resistant
SR-M	Steam reformer membrane	TCD	Thermal conductivity detector
SRNL	Savannah River National Laboratory	TCO	Transparent conductive oxide
SrO	Strontium oxide	Te	Tellurium
SrTiO ₃	Strontium titanate, the proton conducting material	te	Metric ton or tonne (1,000 kg)
SS	Stainless steel	TEA	Triethylamine
SSA	Specific surface area	TEAA	Triethylamine alane adduct
SSAWG	Storage System Analysis Working Group	TEDA	Triethylenediamine
SSR	Solid-state reaction	TEM	Transmission electron microscopy
SSWAG	Storage System Working Analysis Group	TEOA	Triethanolamine
STCH	Solar Thermochemical Hydrogen	TEOM	Tapered element oscillating microbalance
STEM	Scanning transmission electron microscopy	tf	Thin film
STEM	Science, technology, engineering, and mathematics	TFE	Tetrafluoroethylene
STH	Solar-to-hydrogen	TF-RDE:	Thin film rotating disk electrode
STM	Scanning tunneling microscopy	tf-Si	Thin-film silicon
STMBMS	Simultaneous thermogravimetric modulated beam mass spectrometer	TFVE	Trifluorovinyl ether
STP	Standard temperature and pressure	TGA	Thermal gravimetric analysis; thermogravimetric analysis; thermogravimetric analyzer
STS	Scanning tunneling spectroscopy	TGA-DSC	Thermo-gravimetric analysis-differential scanning calorimetry
STTP	Shared Technology Transfer Project	TGA-MS	Thermogravimetric analysis-mass spectrometer
STTR	Small Business Technology Transfer	THF	Tetrahydrofuran
SU/SD	Start-up and shut-down	Ti	Titanium
SV	Space velocity	TiCl ₃	Titanium trichloride
SVD	System volumetric density	TiF ₃	Titanium trifluoride
SWCNT	Single-walled carbon nanotube	TiH ₂	Titanium hydride
SWNH	Single-walled nanohorn	Ti-IRMOF-16	Titanium (Ti) intercalated IRMOF-16
SWNT	Single-wall nanotube	TIO	Technology improvement opportunities
SwRI®	Southwest Research Institute	TiO ₂	Titanium dioxide (anatase)
S _y	Yield strength	TKK	Tanaka Kikinzoku Kogyo K. K.
SYT	Yttrium-doped strontium titanate		
T	Temperature		
T, t	Ton, tonne		
T	Tesla (unit of magnetic induction)		

<i>Tla</i>	Truncated light-harvesting chlorophyll antenna	UHV	Ultra-high vacuum
<i>tla1</i>	Mutant of the Tla1 gene (GenBank Assession No. AF534570)	UIUC	University of Illinois, Urbana-Champaign
<i>tlaR</i>	Mutant of unknown gene with a truncated light-harvesting chlorophyll antenna	UL	Underwriters Laboratory
<i>tlaX</i>	Mutant of unknown gene with a truncated light-harvesting chlorophyll antenna	ULSD	Ultra-low sulfur diesel
TM	Transition metal	um	Micrometer(s)
TMA	Thermal mechanical analyzer	UMC	Unsaturated metal centers
TMB	Trimethylborate	UNCC	University of North Carolina at Charlotte
TMEDA	Tetramethylethane-1,2-diamine; N^1, N^1, N^2, N^2 -tetramethylethane-1,2-diamine	UNLV	University of Nevada, Las Vegas
TMF	The Molecular Foundry	UNLVRF	UNLV Research Foundation
TMG	Tetramethyl guanidine	UNM	University of New Mexico
TMM	Thermal management module	UNR	University of Nevada, Reno
TMPyP	Tetramethylpyridylporphine	UPD	Underpotentially deposited
TNT	Trinitrotoluene	UPE	Ultra-high molecular weight polyethylene
TOC	Total organic content	UPL	Upper potential limit
TOF	Turnover frequency	UPS	Ultraviolet photoelectron spectroscopy
TON	Turnover number	U.S.	United States
TPA	Tripropylamine, Temperature-programmed adsorption	US06	Environmental Protection Agency vehicle driving cycle
TPB	Triple phase boundary	USA	United States of America
TPD	Tonne(s) per day	USANS	Ultra small angle neutron scattering
TPD	Thermally programmed desorption; Temperature-programmed desorption	USB	Universal serial bus
TPO	Temperature-programmed oxidation	USC	University of South Carolina
TPR	Temperature-programmed reduction	USC	University of Southern California
TPV	Through plate voltage	USCAR	United States Council for Automotive Research, U.S. Cooperative Automotive Research
TR	Traditional reactor	USFCC	United States Fuel Cell Council
TRAIN	TrainingFinder Realtime Affiliate Network	USGS	United States Geological Survey
TRL	Technology readiness level	USM	University of Southern Mississippi
tr. oz.	Troy ounce	UT	University of Tennessee
TSA	Temperature swing adsorption	UTC	University of Tennessee, Chattanooga
TV	Test vehicle	UTCP	UTC Power
UC	University of California	UTRC	United Technologies Research Center
UCB	University of California, Berkeley	UV	Ultraviolet
UCF	University of Central Florida	UV-vis	Ultraviolet-visual
UCI	University of California, Irvine	V	Vanadium
UCLA	University of California, Los Angeles	V	Volt
UCONN	University of Connecticut	VA	Vinyl acetate
UCSB	University of California, Santa Barbara	VAC	Volts alternating current
UDDS	Urban Dynamometer Driving Schedule	VACNTs	Vertically aligned carbon nanotubes
UEL	Upper explosive limit	VANTA	Vertically aligned nanotube arrays
UFL	Upper flammability limit	VASP	Vienna ab initio simulation package
UH	University of Hawaii	VB	Valence band
UHP	Ultra-high purity	VBM	Valence band minimum
		VBM	Valence band maximum
		VC	Vanadium carbide
		VC	Vulcan carbon

XIV. Acronyms, Abbreviations and Definitions

VDC	Volts direct current	WO ₃	Tungsten trioxide
VDF	Vinylidene fluoride	Wppm	Weight part(s) per million
VDOS	Vibrational density of states	wt	Weight
vdW	van der Waals	Wt	Watt(s) thermal
VI	Venter Institute	wt%, wt. %	Weight percent (percent by weight)
V-I	Voltage – current	WTP	Well-to-pump
VIR	Voltage-current-resistance	WTP	Water transport plate
V _{mp}	Micropore volume	WTT	Well-to-tank
VMT	Vehicle miles travelled	WTW	Well-to-wheels
VNT	Variable nozzle turbine	w/v	Weight by volume
VOC	Volatile organic compound	WWTP	Waste water treatment plants
VOC	Voltage open circuit	XAFS	X-ray absorption fine structure
vol	Volume	XANES	X-ray absorption near-edge spectroscopy
vol%	Volume percent	XAS	X-ray absorption spectroscopy
V _{pore}	Total pore volume	XC72	High-surface-area carbon support made by Cabot
VRB	Vanadium-redox battery	XES	X-ray emission spectroscopy
W	Tungsten	XPS	X-ray photoelectron spectroscopy, X-ray photon spectroscopy, X-ray photoemission spectroscopy, X-ray photoluminescence spectroscopy
W	Watt(s)	XRD	X-ray diffraction
WAXD	Wide-angle x-ray diffraction	XRF	X-ray fluorescence
WAXS	Wide angle X-ray scattering	Y	Yttrium
WC	Tungsten carbon, tungsten carbide	yr, YR	Year
W/cm ²	Watt(s) per square centimeter	YSZ	Yttria-stabilized zirconia
W _e	Watt(s) electric	ZEV	Zero emission vehicle
WECC	Western Electric Coordinating Council	ZHS	Zinc hydroxystannate
WGS	Water-gas shift	ZIF	Zeolitic imidazolate framework
WGSR	Water-gas shift reactor	Zn	Zinc
WGSMR	Water-gas shift membrane reactor	ZnO	Zinc oxide
Wh	Watt-hour(s)	Zr	Zirconium
W(H ₂)	Gravimetric hydrogen storage capacity	ZrO ₂	Zirconium dioxide
W-h/kg	Watt-hour(s) per kilogram	ZrSPP	Zirconium phosphate sulfophenylphosphonate
W-h/L, Wh/liter, Wh/L	Watt-hour(s) per liter	ZVI	Zerovalent iron
WHSV	Weight hourly space velocity		
Wind2H2	Wind to hydrogen demonstration project		
W/kg	Watt(s) per kilogram		
W/L, W/l	Watt(s) per liter		
W/m-K, W/m.K, W/mK	Watt(s) per meter-Kelvin (unit of thermal conductivity)

XVI. Hydrogen and Fuel Cells Program Contacts

Sunita Satyapal, Program Manager

DOE Hydrogen and Fuel Cells Program

Fuel Cell Technologies Program

DOE Office of Energy Efficiency and Renewable Energy

Phone: (202) 586-2336

E-mail: Sunita.Satyapal@ee.doe.gov

Rick Farmer, Deputy Program Manager

Fuel Cell Technologies Program

DOE Office of Energy Efficiency and Renewable Energy

Phone: (202) 586-1623

E-mail: Richard.Farmer@ee.doe.gov

John Vetrano

Materials Sciences and Engineering Division

Basic Energy Sciences Program

DOE Office of Science

Phone: (301) 903-5976

E-mail: John.Vetrano@science.doe.gov

Guido B. Dehoratiis

Division of Advanced Energy Systems

DOE Office of Fossil Energy

Phone: (202) 586-2795

E-mail: Guido.B.Dehoratiis@hq.doe.gov

Carl Sink

Office of Gas Cooled Reactor Technologies

DOE Office of Nuclear Energy

Phone: (301) 903-5131

E-Mail: Carl.Sink@nuclear.energy.gov

Hydrogen Production and Delivery

Sara Dillich, Acting Hydrogen Production and Delivery Team Leader

Fuel Cell Technologies Program

DOE Office of Energy Efficiency and Renewable Energy

Phone: (202) 586-7925

E-mail: Sara.Dillich@ee.doe.gov

Hydrogen Storage

Ned Stetson, Hydrogen Storage Team Leader
Fuel Cell Technologies Program
DOE Office of Energy Efficiency and Renewable Energy
Phone: (202) 586-9995
E-mail: Ned.Stetson@ee.doe.gov

Fuel Cells

Dimitrios Papageorgopoulos, Fuel Cells Team Leader
Fuel Cell Technologies Program
DOE Office of Energy Efficiency and Renewable Energy
Phone: (202) 586-5463
E-mail: Dimitrios.Papageorgopoulos@ee.doe.gov

Manufacturing R&D

Nancy Garland, Acting Manufacturing R&D Team Leader
Fuel Cell Technologies Program
DOE Office of Energy Efficiency and Renewable Energy
Phone: (202) 586-5673
E-mail: Nancy.Garland@ee.doe.gov

Technology Validation

John Garbak, Technology Validation Team Leader
Fuel Cell Technologies Program
DOE Office of Energy Efficiency and Renewable Energy
Phone: (202) 586-1723
E-mail: John.Garbak@ee.doe.gov

Safety, Codes & Standards

Antonio Ruiz, Safety, Codes and Standards Team Leader
Fuel Cell Technologies Program
DOE Office of Energy Efficiency and Renewable Energy
Phone: (202) 586-0729
E-mail: Antonio.Ruiz@ee.doe.gov

Education

Gregory J. Kleen, Acting Education Team Leader
Fuel Cell Technologies Program
Department of Energy Golden Field Office
Phone: (720) 356-1672
E-mail: Gregory.Kleen@go.doe.gov

Market Transformation

Pete Devlin, Market Transformation Manager
Fuel Cell Technologies Program
DOE Office of Energy Efficiency and Renewable Energy
Phone: (202) 586-4905
E-mail: Peter.Devlin@ee.doe.gov

Systems Analysis

Fred Joseck, Systems Analysis Team Leader
Fuel Cell Technologies Program
DOE Office of Energy Efficiency and Renewable Energy
Phone: (202) 586-7932
E-mail: Fred.Joseck@ee.doe.gov

American Recovery and Reinvestment Act (ARRA) Activities

Sara Dillich, Lead for Fuel Cell Technologies ARRA Activities
and Supervisor for Research & Development
Fuel Cell Technologies Program
DOE Office of Energy Efficiency and Renewable Energy
Phone: (202) 586-7925
E-mail: Sara.Dillich@ee.doe.gov

XVII. Project Listings by State

Alabama

II.K.14	University of Alabama, Tuscaloosa: Protein-Templated Synthesis and Assembly of Nanostructures for Hydrogen Production	267
V.F.1	CFD Research Corporation: Water Transport in PEM Fuel Cells: Advanced Modeling, Material Selection, Testing, and Design Optimization	814
V.F.1	ESI US R&D: Water Transport in PEM Fuel Cells: Advanced Modeling, Material Selection, Testing, and Design Optimization	814

Arizona

II.C.1	Arizona State University: Zeolite Membrane Reactor for Water-Gas Shift Reaction for Hydrogen Production	46
II.K.17	University of Arizona: Formation and Characterization of Semiconductor Nanorod/Oxide Nanoparticle Hybrid Materials: Toward Vectoral Electron Transport in Hybrid Materials.	275
VI.5	Arizona State University: Adaptive Process Controls and Ultrasonics for High-Temperature PEM MEA Manufacture	977

Arkansas

II.G.7	University of Arkansas, Little Rock: PEC-Based Hydrogen Production with Self-Cleaning Solar Concentrator.	154
XII.9	FedEx Freight: Fuel Cell-Powered Lift Truck FedEx Freight Fleet Deployment	1316

California

II.C.2	University of Southern California: Development of Hydrogen Selective Membranes/Modules as Reactors/Separators for Distributed Hydrogen Production.	53
II.F.1	Science Applications International Corporation: Solar High-Temperature Water Splitting Cycle with Quantum Boost.	102
II.F.1	Thermochemical Engineering Solutions: Solar High-Temperature Water Splitting Cycle with Quantum Boost	102
II.F.1	University of California, San Diego: Solar High-Temperature Water Splitting Cycle with Quantum Boost	102
II.F.3	Sandia National Laboratories: Solar Hydrogen Production with a Metal Oxide-Based Thermochemical Cycle	112
II.F.3	Jenike and Johanson: Solar Hydrogen Production with a Metal Oxide-Based Thermochemical Cycle	112
II.G.1	Stanford University: Nano-Architectures for 3 rd Generation PEC Devices: A Study of MoS ₂ , Fundamental Investigations and Applied Research.	123
II.G.1	Board of Trustees of the Leland Stanford Junior University: Nano-Architectures for 3 rd Generation PEC Devices: A Study of MoS ₂ , Fundamental Investigations and Applied Research	123
II.G.2	Stanford University: Semiconductor Materials for Photoelectrolysis	129
II.H.3	J. Craig Venter Institute: Hydrogen from Water in a Novel Recombinant Oxygen-Tolerant Cyanobacterial System	195
II.H.4	University of California, Berkeley: Maximizing Light Utilization Efficiency and Hydrogen Production in Microalgal Cultures	200
II.J.4	Physical Optics Corporation: Photochemical System for Hydrogen Generation.	225
II.K.1	Stanford University: SISGR: Using <i>In vitro</i> Maturation and Cell-free Evolution to Understand [Fe-Fe]hydrogenase Activation and Active Site Constraints	228
II.K.12	University of California, Santa Cruz: Hydrogen Generation Using Integrated Photovoltaic and Photoelectrochemical Cells	260

California (Continued)

II.K.20	California Institute of Technology: Fundamental Optical, Electrical, and Photoelectrochemical Properties of Catalyst-Bound Silicon Microwire Array Photocathodes for Sunlight-Driven Hydrogen Production	283
III.1	Sandia National Laboratories: Hydrogen Embrittlement of Structural Steels	299
III.5	Lawrence Livermore National Laboratory: Demonstration of Full-Scale Glass Fiber Composite Pressure Vessels for Inexpensive Delivery of Cold Hydrogen	316
III.5	Spencer Composites Corporation: Demonstration of Full-Scale Glass Fiber Composite Pressure Vessels for Inexpensive Delivery of Cold Hydrogen	316
III.8	HyGen Industries: Development of a Centrifugal Hydrogen Pipeline Gas Compressor.	331
III.14	Lawrence Livermore National Laboratory: Thermodynamic Modeling of Rapid Low Loss Cryogenic Hydrogen Refueling.	358
III.14	Linde LLC: Thermodynamic Modeling of Rapid Low Loss Cryogenic Hydrogen Refueling	358
IV.A.8	Sandia National Laboratories: Tunable Thermodynamics and Kinetics for Hydrogen Storage: Nanoparticle Synthesis Using Ordered Polymer Templates	416
IV.A.8	Lawrence Livermore National Laboratory: Tunable Thermodynamics and Kinetics for Hydrogen Storage: Nanoparticle Synthesis Using Ordered Polymer Templates	416
IV.C.2	University of California, Los Angeles: A Joint Theory and Experimental Project in the Synthesis and Testing of Porous COFs/ZIFs for On-Board Vehicular Hydrogen Storage	439
IV.C.7	H2 Technology Consulting LLC: Weak Chemisorption Validation	464
IV.C.9	University of California, Los Angeles: Hydrogen Storage in Metal-Organic Frameworks	474
IV.D.1	Jet Propulsion Laboratory: Hydrogen Storage Engineering Center of Excellence	479
IV.D.1	California Institute of Technology: Hydrogen Storage Engineering Center of Excellence	479
IV.D.4	Jet Propulsion Laboratory: Key Technologies, Thermal Management, and Prototype Testing for Advanced Solid-State Hydrogen Storage Systems	494
IV.D.4	California Institute of Technology: Key Technologies, Thermal Management, and Prototype Testing for Advanced Solid-State Hydrogen Storage Systems	494
IV.E.4	Sandia National Laboratories: Analysis of H ₂ Storage Needs for Early Market Non-Motive Fuel Cell Applications	554
IV.E.7	H2 Technology Consulting LLC: Best Practices for Characterizing Engineering Properties of Hydrogen Storage Materials	567
V.D.1	Jet Propulsion Laboratory: Advanced Cathode Catalysts and Supports for PEM Fuel Cells	699
V.D.4	University of California, Riverside: Extended, Continuous Pt Nanostructures in Thick, Dispersed Electrodes	719
V.D.4	Stanford University: Extended, Continuous Pt Nanostructures in Thick, Dispersed Electrodes	719
V.D.5	Jet Propulsion Laboratory: Nanosegregated Cathode Catalysts with Ultra-Low Platinum Loading	723
V.D.7	University of California, Riverside: The Science and Engineering of Durable Ultralow PGM Catalysts	734
V.D.8	Lawrence Berkeley National Laboratory: Molecular-Scale, Three-Dimensional Non-Platinum Group Metal Electrodes for Catalysis of Fuel Cell Reactions.	738
V.E.2	Lawrence Berkeley National Laboratory: Durability Improvements Through Degradation Mechanism Studies	788
V.E.7	Lawrence Berkeley National Laboratory: Accelerated Testing Validation	810
V.F.2	Sandia National Laboratories: Development and Validation of a Two-Phase, Three-Dimensional Model for PEM Fuel Cells	818
V.F.2	Lawrence Berkeley National Laboratory: Development and Validation of a Two-Phase, Three-Dimensional Model for PEM Fuel Cells	818
V.F.2	University of California, Irvine: Development and Validation of a Two-Phase, Three-Dimensional Model for PEM Fuel Cells	818
V.F.6	Lawrence Berkeley National Laboratory: Transport Studies Enabling Efficiency Optimization of Cost-Competitive Fuel Cell Stacks	837

California (Continued)

V.F.7	Lawrence Berkeley National Laboratory: Fuel Cell Fundamentals at Low and Subzero Temperatures	841
V.G.1	Jet Propulsion Laboratory: Novel Approach to Advanced Direct Methanol Fuel Cell (DMFC) Anode Catalysts	846
V.G.2	QuantumSphere Inc.: Novel Materials for High Efficiency Direct Methanol Fuel Cells	850
V.G.4	University of California, Riverside: Advanced Materials and Concepts for Portable Power Fuel Cells	858
V.I.1	Jet Propulsion Laboratory: Resonance-Stabilized Anion Exchange Polymer Electrolytes	872
V.J.2	Honeywell Aerospace: Development of Thermal and Water Management System for PEM Fuel Cell	883
V.K.2	Intelligent Energy: Development and Demonstration of a New Generation High Efficiency 10 kW Stationary PEM Fuel Cell System	894
V.K.3	University of California, Davis: Research & Development for Off-Road Fuel Cell Applications	899
VI.3	UltraCell Corporation: Modular, High-Volume Fuel Cell Leak-Test Suite and Process	968
VI.9	Quantum Fuel Systems Technologies Worldwide, Inc.: Development of Advanced Manufacturing Technologies for Low Cost Hydrogen Storage Vessels	995
VI.9	Lawrence Livermore National Laboratory: Development of Advanced Manufacturing Technologies for Low Cost Hydrogen Storage Vessels	995
VII.3	Mercedes-Benz Research & Development North America, Inc.: Hydrogen to the Highways – Controlled Hydrogen Fleet and Infrastructure Demonstration and Validation Project	1027
VII.6	University of California, Irvine: California Hydrogen Infrastructure Project	1040
VII.9	California State University, Los Angeles: Sustainable Hydrogen Fueling Station, California State University, Los Angeles	1050
VIII.1	Sandia National Laboratories: Hydrogen Safety, Codes and Standards R&D – Release Behavior	1061
VIII.2	Sandia National Laboratories: Risk-Informed Safety Requirements for H2 Codes and Standards Development	1067
VIII.4	Sandia National Laboratories: Hydrogen Materials and Components Compatibility	1075
VIII.5	Sandia National Laboratories: Component Testing for Industrial Trucks and Early Market Applications	1079
VIII.6	Steele Consulting: National Codes and Standards Coordination	1083
VIII.10	City of Santa Fe Springs: Hydrogen Safety Panel	1100
VIII.12	California Fuel Cell Partnership: Hydrogen Emergency Response Training for First Responders	1107
VIII.13	Lawrence Livermore National Laboratory: Hydrogen Safety Training for Researchers and Technical Personnel	1110
VIII.14	Intelligent Optical Systems, Inc.: Hydrogen Leak Detection System Development	1114
IX.3	University of California, Berkeley: Hydrogen Education State Partnership Program	1139
IX.6	Humboldt State University: H2L3: Hydrogen Learning for Local Leaders	1148
IX.9	California State University, Los Angeles: Hydrogen and Fuel Cell Education at California State University, Los Angeles	1158
IX.10	Humboldt State University Sponsored Programs Foundation: Hydrogen Energy in Engineering Education (H ₂ E ³)	1161
IX.10	University of California, Berkeley: Hydrogen Energy in Engineering Education (H ₂ E ³)	1161
IX.15	University of California, Berkeley: Hydrogen Technology and Energy Curriculum (HyTEC)	1180
IX.15	Humboldt State University: Hydrogen Technology and Energy Curriculum (HyTEC)	1180
X.1	Sandia National Laboratories: Fuel Cell Mobile Lighting	1191
X.2	Longitude 122 West, Inc.: Economic Analysis of Bulk Hydrogen Storage for Renewable Utility Applications	1196
X.6	Oorja Protonics, Inc.: Direct Methanol Fuel Cell Material Handling Equipment Demonstration	1209
X.8	Lawrence Livermore National Laboratory: Incorporation of Two Ford H ₂ ICE Buses into the Shuttle Bus Fleet	1214
X.9	Sandia National Laboratories: PEM Fuel Cell Systems for Commercial Airplane Systems Power	1217

California (Continued)

XI.4	Sandia National Laboratories: Analysis of the Effects of Developing New Energy Infrastructures	1244
XI.4	Andy Lutz: Analysis of the Effects of Developing New Energy Infrastructures	1244
XI.11	Lawrence Livermore National Laboratory: Energy Informatics: Support for Decision Makers through Energy, Carbon and Water Analysis	1270
XII.2	Jadoo Power, Inc.: Jadoo Power Fuel Cell Demonstration	1291
XII.4	Electricore, Inc.: Solid Oxide Fuel Cell Diesel Auxiliary Power Unit Demonstration	1297
XII.5	Alteryg Systems, Folsom: Demonstrating Economic and Operational Viability of 72-Hour Hydrogen PEM Fuel Cell Systems to Support Emergency Communications on the Sprint Nextel Network	1300
XII.6	Peek Site-Com, Inc.: PEM Fuel Cell Systems Providing Backup Power to Commercial Cellular Towers and an Electric Utility Communications Network	1304
XII.6	Jeffrey Rome and Associates: PEM Fuel Cell Systems Providing Backup Power to Commercial Cellular Towers and an Electric Utility Communications Network	1304
XII.12	University of California, Irvine: Highly Efficient, 5 kW CHP Fuel Cells Demonstrating Durability and Economic Value in Residential and Light Commercial Applications.	1325

Colorado

II.A.2	National Renewable Energy Laboratory: Distributed Bio-Oil Reforming	29
II.C.3	Colorado School of Mines: High Performance Palladium-Based Membrane for Hydrogen Separation and Purification	58
II.D.1	Colorado School of Mines: Advanced Hydrogen Transport Membranes for Coal Gasification	62
II.D.3	United Technologies Research Center: Advanced Palladium Membrane Scale Up for Hydrogen Separation.	69
II.E.4	National Renewable Energy Laboratory: Renewable Electrolysis Integrated System Development and Testing	92
II.E.4	Spectrum Automation Controls: Renewable Electrolysis Integrated System Development and Testing.	92
II.E.6	National Renewable Energy Laboratory: Hour-by-Hour Cost Modeling of Optimized Central Wind-Based Water Electrolysis Production	98
II.F.3	University of Colorado: Solar Hydrogen Production with a Metal Oxide-Based Thermochemical Cycle	112
II.F.4	University of Colorado: Solar-Thermal ALD Ferrite-Based Water Splitting Cycle	118
II.G.2	National Renewable Energy Laboratory: Semiconductor Materials for Photoelectrolysis	129
II.G.3	Lawrence Livermore National Laboratory: Characterization and Optimization of Photoelectrode Surfaces for Solar-to-Chemical Fuel Conversion.	134
II.G.5	MVSystems, Incorporated: Photoelectrochemical Hydrogen Production	146
II.G.6	National Renewable Energy Laboratory: Critical Research for Cost-Effective Photoelectrochemical Production of Hydrogen	150
II.G.8	National Renewable Energy Laboratory: Photoelectrochemical Hydrogen Generation from Water Using $\text{TiSi}_2\text{-TiO}_2$ Nanotube Core-Shell Structure	160
II.G.12	National Renewable Energy Laboratory: Photoelectrochemical Materials: Theory and Modeling.	176
II.G.13	Synkera Technologies Inc.: Nanotube Array Photoelectrochemical Hydrogen Production.	181
II.H.1	National Renewable Energy Laboratory: Biological Systems for Hydrogen Photoproduction.	185
II.H.2	National Renewable Energy Laboratory: Fermentation and Electrohydrogenic Approaches to Hydrogen Production	190
II.H.5	National Renewable Energy Laboratory: Purdue Hydrogen Systems Laboratory: Hydrogen Production	203
II.I.1	National Renewable Energy Laboratory: H ₂ A Production Model Updates	207
II.K.5	National Renewable Energy Laboratory: Structural, Functional, and Integration Studies of Solar-Driven, Bio-Hybrid, H ₂ -Producing Systems.	240

Colorado (Continued)

II.K.8	National Renewable Energy Laboratory: Regulation of H ₂ and CO ₂ Metabolism: Factors Involved in Partitioning of Photosynthetic Reductant in Green Algae	248
II.K.21	National Renewable Energy Laboratory: New Directions for Efficient Solar Water Splitting Based on Two Photosystems and Singlet Fission Chromophores	286
III.4	National Renewable Energy Laboratory: Hydrogen Delivery Analysis	312
IV.C.7	National Renewable Energy Laboratory: Weak Chemisorption Validation	464
IV.D.1	National Renewable Energy Laboratory: Hydrogen Storage Engineering Center of Excellence	479
IV.D.2	National Renewable Energy Laboratory: System Design, Analysis, Modeling, and Media Engineering Properties for Hydrogen Energy Storage	486
IV.E.5	National Renewable Energy Laboratory: Analysis of Storage Needs for Early Motive Fuel Cell Markets	558
IV.G.1	National Renewable Energy Laboratory: Purdue Hydrogen Systems Laboratory: Hydrogen Storage	585
V.A.1	National Renewable Energy Laboratory: Analysis of Laboratory Fuel Cell Technology Status – Voltage Degradation	605
V.A.7	National Renewable Energy Laboratory: Enlarging the Potential Market for Stationary Fuel Cells Through System Design Optimization	634
V.B.1	National Renewable Energy Laboratory: Effect of System Contaminants on PEMFC Performance and Durability	640
V.B.1	Colorado School of Mines: Effect of System Contaminants on PEMFC Performance and Durability	640
V.C.1	Colorado School of Mines: Membranes and MEAs for Dry, Hot Operating Conditions	662
V.C.6	Colorado School of Mines: Novel Approaches to Immobilized Heteropoly Acid (HPA) Systems for High Temperature, Low Relative Humidity Polymer-Type Membranes	685
V.C.9	BekkTech LLC: Lead Research and Development Activity for DOE's High Temperature, Low Relative Humidity Membrane Program	696
V.D.4	National Renewable Energy Laboratory: Extended, Continuous Pt Nanostructures in Thick, Dispersed Electrodes	719
V.D.9	National Renewable Energy Laboratory: Tungsten Oxide and Heteropoly Acid Based System for Ultra-High Activity and Stability of Pt Catalysts in PEM Fuel Cell Cathodes	745
V.D.9	Colorado School of Mines: Tungsten Oxide and Heteropoly Acid Based System for Ultra-High Activity and Stability of Pt Catalysts in PEM Fuel Cell Cathodes	745
V.D.9	University of Colorado: Tungsten Oxide and Heteropoly Acid Based System for Ultra-High Activity and Stability of Pt Catalysts in PEM Fuel Cell Cathodes	745
V.G.1	National Renewable Energy Laboratory: Novel Approach to Advanced Direct Methanol Fuel Cell (DMFC) Anode Catalysts	846
V.G.1	Colorado School of Mines: Novel Approach to Advanced Direct Methanol Fuel Cell (DMFC) Anode Catalysts	846
V.I.2	Versa Power Systems: Advanced Materials for RSOFC Dual Mode Operation with Low Degradation	876
V.L.6	Colorado School of Mines: Biomass Fuel Cell Systems	927
VI.1	National Renewable Energy Laboratory: Fuel Cell Membrane Electrode Assembly Manufacturing R&D	959
VII.1	National Renewable Energy Laboratory: Controlled Hydrogen Fleet and Infrastructure Analysis	1017
VII.5	National Renewable Energy Laboratory: Technology Validation: Fuel Cell Bus Evaluations	1036
