Update on Strategic Plan for Wind Plant Reliability

DOE Wind and Water Power Program

Carsten Westergaard
Jonathan Keller

2014
What is Atmosphere to Electrons (A2e)?

1. *A technology initiative* to enable design and deployment of low-cost *smart wind power plants*.

2. *A novel U.S. Department of Energy (DOE) management construct* leveraging a diverse expertise and stakeholder groups.
How Will Smart Wind Plants Overcome These Challenges?

**Challenges**
- Wind plant energy losses of 20% or higher
- Major components not meeting 20-year design life
- Investment risk has inflated the cost of capital
- Inaccurate forecasts cost industry $300M+/year

**Smart Wind Plant Objectives**
- Increase plant capacity factors from 0.39 to 0.50
- Reduce losses from 20% to 12%
- Extend component/system design life from 20 to 30 years
- Reduce installed capital costs from 1,615 to 1,454 $/kilowatt (kW)
- Reduce cost of capital from 8.5% to 7.5% for land (larger opportunity for offshore wind)
- Improve day- and hour-ahead forecast accuracy by 10%–20%

**A2e LCOE Impact**
- $65/megawatt-hour (MWh) to $42/MWh (39% reduction from 2014 to 2030)

Note: Starting points and trajectories (2014-2030) for A2e objectives and LCOE targets are from the 2014 NREL LCOE Memo to WWPTO, which builds from the Wind Vision study, the 2013 Wind Market Report, and WWPTO LCOE analysis.
Fiscal Year (FY) 2014 Execution Timeline

Major accomplishments to date

1. Completed external merit review
   – External reviewers were quite pleased with A2e’s direction towards wind plants

2. Completed integrated strategic plan
   – Ready for external merit review in February 2015

3. Completed many meetings with external stakeholders, both domestic and international, in industry and academia
   – Topics included: high-fidelity modeling, verification and validation framework development, experimental campaign design, aeroacoustics, advanced controls, reliability, design methods, data archival and portal, performance risk, uncertainty, and finance

4. Realigned FY15 portfolio to reflect A2e priorities
   – Capacity to initiate new starts limited by flat funding levels.

Why is Wind Plant Reliability Important for an R&D Program?

- Reliability is a fundamental discipline that affects all aspects of LCOE:
  - Operational expenditure (OpEx) costs – scheduled and unscheduled
  - Financing – through lack of reliability and subsequent uncertainty
  - Annual energy production (AEP) – through unavailability
  - Capital expenditure (CapEx) costs – through overdesign/underdesign and testing

- The potential:
  - O&M is estimated to be 25% of revenue for land-based wind
  - U.S. wind O&M is a $1.6B-$3B market on its way to become a $5B market
  - Direct CapEx improvement potential is currently unknown

- The opportunity:
  - Aggregated data over larger volumes and cross-sections will reduce uncertainty and fill in knowledge gaps not otherwise available for the individual
  - Support an industry supply chain as it is changing towards more standardization (similar to the car/aerospace hybrid industry) and new products
  - Need for smart fleet management tools supporting an evolving O&M industry.
The Life of Components in a Wind Plant

The expectation:
• Infant mortality
• Random failures at constant rate
• Opportunity for life extension

What we fear:
• "Black swan" events shorten life and prevent future opportunity

What we could achieve:
• Monitor and quantify remaining life
• Reduce quantifiable uncertainty by understanding failure and events.
## Environmentally Induced Reliability Events

The data on environmental is not quantified at this stage and are fleet average. I.e. icing is a regional effect.
Aggregating data over larger volumes and cross sections will reduce uncertainty and fill in knowledge gaps not otherwise possible for the individual. Fundamental knowledge gaps relating to reliability exist all the way from the wind plant aerodynamics level to the part microstructure level. Although the wind industry has improved tremendously over the past two decades, there is a need to support the supply chain as it changes towards more standardization to achieve a vehicle or aerospace style of reliability. Existing design standards no longer support the growing wind industry at the plant level and do not enable effective risk management at any level. The role of DOE is to identify opportunities that can reduce existing uncertainty and preempt future uncertainty for owner/operators.

The vision of the Wind Plant Reliability focus area is:

**Reliable delivery of electricity and significantly reduced costs by increasing inherent reliability and reducing remaining useful life uncertainty.**
Work Package #1

**Continuously validate assumptions in interaction with industry.**
The reliability collaboratives (RCs) have been proven effective and are highly valued by industry.

They provide organization that industry needs, driven by laboratory technology leadership and fundamental research delivered by the resulting separate WPs investigating common issues without breaching proprietary considerations in the areas of rotors, drivetrains, actuators, and electrical delivery systems.

They will be supported by benchmarking against aggregated data to select research objectives and develop requirements for standards.

From a national perspective, benchmarks will continue to drive reliability transparency and the success of the industry. This WP will drive prioritization of the other WPs and deliver a national database and benchmark for owners.
Benchmarking and Analysis

Stakeholders have different insights but no overarching insight

- North American Electric Reliability Corporation (NERC) (future)

OEMs only have own platforms and generally only in warranty period

- Typical component supplier

Suppliers to multiple OEMs and nonwind applications have large amounts of detailed knowhow

Data depth/amount

- CREW
- Blade Reliability Collaborative (BRC)
- Gearbox Reliability Collaborative (GRC)

Typical OEM

Advanced owners

Owners have multiple platforms from multiple OEMs
Define the external challenge and its impact.

Environmental conditions have a large impact on reliability. In the design and siting phases, they are dealt with through the standards and siting exercises assuming relatively generic conditions.

There may be regional understanding of lightning, icing, erosion, extreme winds, and corrosion, but no linkage to the actual consequences that are important to insurance providers, owners, designers, and eventually design standards. This WP will characterize the effects of U.S.-specific weather events on reliability.
Lightning: Regional Risk Variation

  - Based on data from 2,800 “small turbines” in northern European Union (<15 days) and inner Germany (<35 days of thunderstorms)
  - Annual failure rate 0.4% to 1.4%
- United States has 5 to 100 days of thunderstorms, 0.3% to 5%
- Midwest has ~55 days with an annual failure rate up to 3%
- Subconclusion:
  - Fleet average without considering regional exposure is fairly meaningless
  - A well document standard for normalization combined with a national fleet average could improve our understanding
  - Many U.S. owners have more accumulated experience than what the IEC standard is based upon.

Sources: NOAA.gov, Cannata 2014, Coffery 2014, Nissam 2013, LM Wind power
Lightning: Technology Bias and Size Bias

- Lightning risk, according to IEC TR 61400-24 and ported from building code, suggest risk is proportional to height squared, including landscape topology.
- Experience shows much higher height dependency (~R^4).
- On the flip side, improved lightning protection systems are reported to have as much as tenfold improvement.
- Subconclusion: Historical fleet average will not predict the future without significant considerations to technology and size correction.

Sources: Cannata 2014, Coffery 2014, Green 2014, LM Wind power
Directional Analysis of System Control and Data Acquisition (SCADA) Data

Power “Rose”

Variability “Rose”
Operational Quantification

- Observation: High power extraction relative to average performance occurs with low variance.

- If low variance equals low rates of fatigue and wear, then low rates of failure should be observed as a function of direction.

- Working hypothesis: Direction plays a major role and is a simple way to quantify power and reliability.

- Can we link data mining of SCADA and apply a simple metric for reliability?
Perform research to increase inherent reliability.

The major activities in the rotor and drivetrain are an outgrowth of existing DOE research. In contrast, major activities in power conversion and grid interconnection are a result of industry feedback.

Each technical work package contains testing and modeling activities as directed by the reliability collaboratives and benchmarking and is focused on delivering the data and knowledge for the supply chain to increase the inherent, or baseline, reliability of components, the wind turbines, and the plant connection to the electrical grid.
1.5-MW Testing and Modeling

• Measurements and tests
  – Main shaft (input) and high-speed shaft (reaction) torque and bending loads
  – No need for component (gear tooth or bearing race) instrumentation
    • Models predict component stresses accurately, given the loads
  – Rotor, tower, meteorological tower, and SCADA data to characterize turbine operational state
  – Actual controller action can differ widely from design assumptions
  – A 2.5-MW dynamometer, DOE 1.5-MW turbine, and controllable grid interface are stepping stones to field tests

• Analysis and modeling
  – Process loads to characterize design load cases and transients
    • A2e reference load distribution
  – Develop and model generic drivetrain to explore design deficiencies.
Develop tools and practices producing inherent reliability.

Scheduled and reactive maintenance require significant effort. There is a lack of accurate diagnostic and prognostic capabilities in the wind industry; however, these capabilities are critical for optimized O&M strategies and reduced O&M costs.

State-of-the-art operations centers at OEMs have increased the availability of wind plants to 98%–99% by intense monitoring, immediate responses, and sophisticated escalation procedures. The costs have risen, however, and proactive practices are only in their infancy stage.

This WP will deliver methodologies and analysis capabilities to move from reactive to proactive maintenance, starting with obtaining metrics for major component severity damage levels to quantify remaining useful life.
Work Package and Focus Area Interactions

**INPUT**

- Continuously validate assumptions in interaction with industry, through collaborative industry benchmarks
- Define the external challenge and its impact
- Focus on select scientific research of importance to increase inherent reliability
- Develop tools and practices producing inherent reliability
- Disseminate in interaction with industry and other stakeholders, through collaborative industry benchmarks

**OUTPUT**

- Atmospheric science, plant aerodynamics
- Controls and experimental campaigns
- Controls
- Environment and turbine-turbine driven reliability
- Structure and materials
- Monitor, plan, operate, and apply new methods
- Methods
- Tools
- Best practices
- Fact-based risk assessment
- Integrated system design input
  - Computational tools input/validation
  - Fact-based validation for standards
  - Environmental site risks map

**Feedback loop**

- Fact-based risk assessment
- Integrated system design input
  - Computational tools input/validation
  - Fact-based validation for standards
  - Environmental site risks map
- Atmospheric science, plant aerodynamics
- Controls and experimental campaigns
- Controls
- Environment and turbine-turbine driven reliability
- Structure and materials
- Monitor, plan, operate, and apply new methods
- Methods
- Tools
- Best practices
- Disseminate in interaction with industry and other stakeholders, through collaborative industry benchmarks
